GETTY CENTER LIBRARY

# INDEX.

## LIST OF ILLUSTRATIONS.

ADVERTISING MACHINE, 780
Air-pump, 497
Alarum, 424
Aphengescope, 236
Appliances for Work, 136, 180
Arch, Lattice Girder, 276
Arches, 96, 205, 376
Armourers' Hammers, 807
Ash-pan, 566

BACKSTAY, 237
Balloons, Toy, 134
Banjo Case, 139
Bank, 492
Barometer, 477
Bassinette, 274
Bath, A Folding, 645
Battery Plates, 36
Bellows, Fletcher's, 356
Bell-ringer's Table, 380
Belt (Leather) Joints, 779
Bench Stop, 229, 647
Bench and Tool Chest, 223
Bending Brass Treads, 441
Bent Iron, Hall Lamp, 321
Bevels, Instrument for, 299
Billiard-cue Tip, 203
Bird Cage, 59
Blinds, Venetian, 86
Blow-lamp, 269; -pipe, 282, 356, 810
Boiler, 317, 589, 812
Boiler Pump, 684
Bookbinding, 28
Book-box, 2, 37
Book-rest, 648
Bookshelf, 252, 520, 565, 685
Boot for Shortened Leg, 490
Boot Repairing, etc., 12, 112, 201, 280, 345, 405, 516, 534, 796; Heels, 637, Bottle Top, 252 [796; Lasts, 253, 301
Box, Folding, 504
Brackets, 198, 520, 811
Brass-melting Furnace, 429
Bread-cutter, 526
Bristles, 716
Bromide, Apparatus for Making, 558
Bunsen Burner, 636
Butter Cooler, 826

CAGE, FOR SQUIRREL, 365; Rat, 382
Camera Lucida for Micro. Sketching,
Camera Obscura, 396 [326
Candelabrum, etc., 593
Candlestick, 43
Cane, Grooving, 510
Canoe, Canvas, 412
Canopy for Bed Hangings, 241, 242
Canvas, Stretching, 644
Cap, Paper, 43
Carpet Planning, 22
Carpenter's Rule, 381
Carpentry, Stage (*see Stage*)
Carts, Newspaper, 78; Oxford, 525; Tip-cart, 401, 403
Case for Stuffed Birds, 44
Cask Tilter, 266
Casket, 409
Castors, 410; Ball-bearing, 218; Cantilever, 106; Fixing, 507
Castor-pin, 699
Ceiling Panels, 825
Chain-coupling Link, 759
Charcoal Heater, 574
Chess-board, 770
Chicken-rearing Appliances, 737
Child's Carriage, 426
Chimneys, 281; Pot, 266
Chuck, 490, 604
Clock Case, 385, 387, 473, 811
Clocks, American, 236; Gravity, 820; Sand, 333; Water, 699
Closet for the Hall, 145
Clothes Pegs, Novel Use for, 250
Clothes and Tool Chest, 156
Coil, Dr. Spanner's Induction, 282
Coil heated from Register Grate, 221
Colour for Cornice, etc., 210
Colour in our Homes, 689
Compass Work, 231
Concrete Building, 60
Coop for Hen, etc., 788
Copying Machine, 554
Cordage (*see Knotting, etc.*)
Cork Ornaments, etc., 761
Cornice, 210; Frieze and Dado, 667
Cottages, Plan of, 724
Counter Case, 301
Cowl, 266
Cramp Boards, 253
Cramps, 21, 299, 619
Creaser, 270
Crests, 29
Cricket Bat Splices, 75
Curves, Methods of Striking, 475
Cycles, 524; Anti-vibrator, 407, 525; Bearings, 571; Crank and Shaft, 620; House, 573, 585; Parts, 812; Stand for Training, 635 (*see also* Cycloidal Curve, 238 [*Safety Bicycle*)
Cyltine Manifold Copier, 554

DADOES, 715, 753
Damp Course, 556
Decoration of, Fireplace, 651; Study,
Design for Corner, 637 [617, 618
Design for Embossed Work in
Design for Sign, 397 [Leather, 817
Designs for Repoussé Work, 305, 377
Desk and Chair, 29
Diamond Pattern Lumber, Machine
Die for Stamping, 651 [Cut, 170
Distance Register, 460
Doll's House, 221
Doors, Posts of, 629; Sliding, 412
Dove-cot, 289
Dovetailing, 285, 389, 637, 691
Draught-board, 745 [235
Drawers, 310, 792; Irregular Form,
Drawing, Mechanical, 105
Drawings for Patent Office, 215
Dresser for Kitchen, 529, 530
Drinking-flask, 666
Drying-horse for Boots, 313

EAR-RINGS, 20, 101, 164, 165
Easel, Artist's, 350, 478, 614
Egg Saucepan, 422
Eggs, Incubation of, 737
Elbow-pipe, Marking, 477
Electric Bell, 804; Lines, 700, 733
Electric Lamps, 27 [757
Electrical Appliances, 465, 584, 661, 668,
Engines:— Hot-air, 570, 586, 717; Launch, 346; Petroleum, 618; Quarter H.-P., 89, 260, 261, 328, 329, 420, 501, 581, 708

FAIRY BELLS, 572; to Piano, 28
Fastener for Shirt Studs, 90
Fender, Kitchen, 219; Scroll for, 349
Fiddle Case, 423
Fire-guards, Wire, 601
Fireplace, 449, 760
Fitment, Hanging, 565
Flower, Box, 203; Holder, 505; Stand,
Foot-warmer, 806 [107
Force-pump, 717 [732
Forge, Portable, 705; Blacksmith's,
Fountain, Self-acting, 657, 748
Fowls'-house, 62, 673
Frame for Coins, 285
Framework Testing, 326, 426, 533
Framing, Hints on, 68
Fret Machine, 155, 461, 478, 540, 827
Fretwork, 39, 41, 546, 637, 763
Fryer for Fish and Potatoes, 476
Furnace, Section of, 637
Furniture:— Armchair, 661; Bedroom Suite, Combination, 341; Bedstead, 317, 413, 645; Bookcase, 159, 236, 317, 353, 565; Chair and Desk, 29; Chair, Antique Dutch, 790; Corner Bookcase, 652; Hanging Bookcase, 663; Cabinet, 433, 434, 577, 579; Card-table, 745; Coal-box, 75, 440; Commode, 555; Couch, 236; Couch-bedstead, 413; Desk and Chair, 29; Drawers, Chest of, 792; Fender, 219, 349; Hall-stand, 49, 50; Hat or Clothes Stand, 266; Hat-stand of Rails, 213; Jewel Cabinet, 109; Medicine Chest, 233, 520; Mirror, 653, 664; Music Canterbury, 3, 4, and Frontispiece; Ottoman Couch, 204, 824; Secrétaire, 643; Sofa-bedstead, 317; Table, 121, 404, 808; Umbrella-stand, 213; Wardrobe, 105, 177; Wash-hand Stand, 251; Whatnot, 369; Writing Cupboard, 1, 2, 3; Writing Table, etc., 353

GALVANOMETER, 318, 430
Garden, Arches, 740, 741; Decoration, 129; Label, 218; Tool-house, 225
Gas Bag, 172; Globes, Wire, 533
Girder, "Fish-belly," 163
Glass Bevelling, Shapes for, 40
Glass Case, Framing, 493
Glass, Cutting, 476; in Furniture, 117;
Greenhouse, 363 [Lead Pattern, 685
Grindstone, 450
Gun-rack, 60, 494; 110-ton, 382

HAIR CURLING AND CRIMPING, 619
Hall-marks, 521
Hall and Staircase, 709; Lantern, 320
Halving, 691
Harness, Pad, 743; Top Hame, 487
Hat Pegs, 517
Helioscope, 526
Hen-coop, 108
Hive Observatory, 285
Hive for Transportation, 12
Homacoustic, The, 762
Honey Extractor, 298
Hot-water Fitting, 13, 252, 397, 742

INCUBATOR, 75, 561, 605, 609, 731, 796
Inlaying Monogram, 395, and *see M*
Iron Joists, Fixing Wood Floor, 573

JACK, POPE'S CARRIAGE, 138 [563
Joints, Mortise, Tenon, and Halved,

KELTIC ORNAMENT, 721
Kiln, 93
Knotting, Spliceing, and Working Cordage, 65, 137, 200, 245, 309, 361, 469, 552, 553, 613, 677, 725

LABOUR-SAVING APPLIANCES, 441
Lace Frame, 430
Lamp, 253; for Lantern, 597; Wicks,
Landing Nets, 775 [Trimming, 26
Lantern, Cabinet, 316; Carrier, 685; Curtain, 205; Lamp for, 597; Microscope, 749; Objective, 219
Lathe, 453, 569, 714; Attachment, 666; Chuck, 490, 604; Headstock for, 813; Mandrel, 430; Overhead, 716;
Lead Joint Runner, 425 [Treadle, 621
Lenses, 461
Limelight Apparatus, 220
Lithography, 149, 231, 232, 297, 450, 451
Locomotive Steam Chest, 316

MACRAMÉ BOARD, 681
Machines and Appliances:— Advertising, 780; Appliances, 136; Bundling Firewood, 590; Dovetailing, 692; Drilling, 10; Mitring, 9, 170; Planing, 346; Squaring, 9; Wire Crimping, 120
Magnesium Lamp, 62
Mandoline, 777
Mantelboards, 265
Masons' Work, 96, 98, 185, 265, 324, 376
Mast, Scarfing, 523
Mat Making, 750
Meat Safe, 216
Medicine Cupboard, 233, 520
Metronome, 628
Microscope, 749, 796; with Polariscope
Microscope Lamp, 51 [fitted, 631

## An Illustrated Magazine of Practice and Theory

### FOR ALL WORKMEN, PROFESSIONAL AND AMATEUR.

[*All Rights reserved.*]

Vol. III.—No. 105.] SATURDAY, MARCH 21, 1891. [Price One Penny.

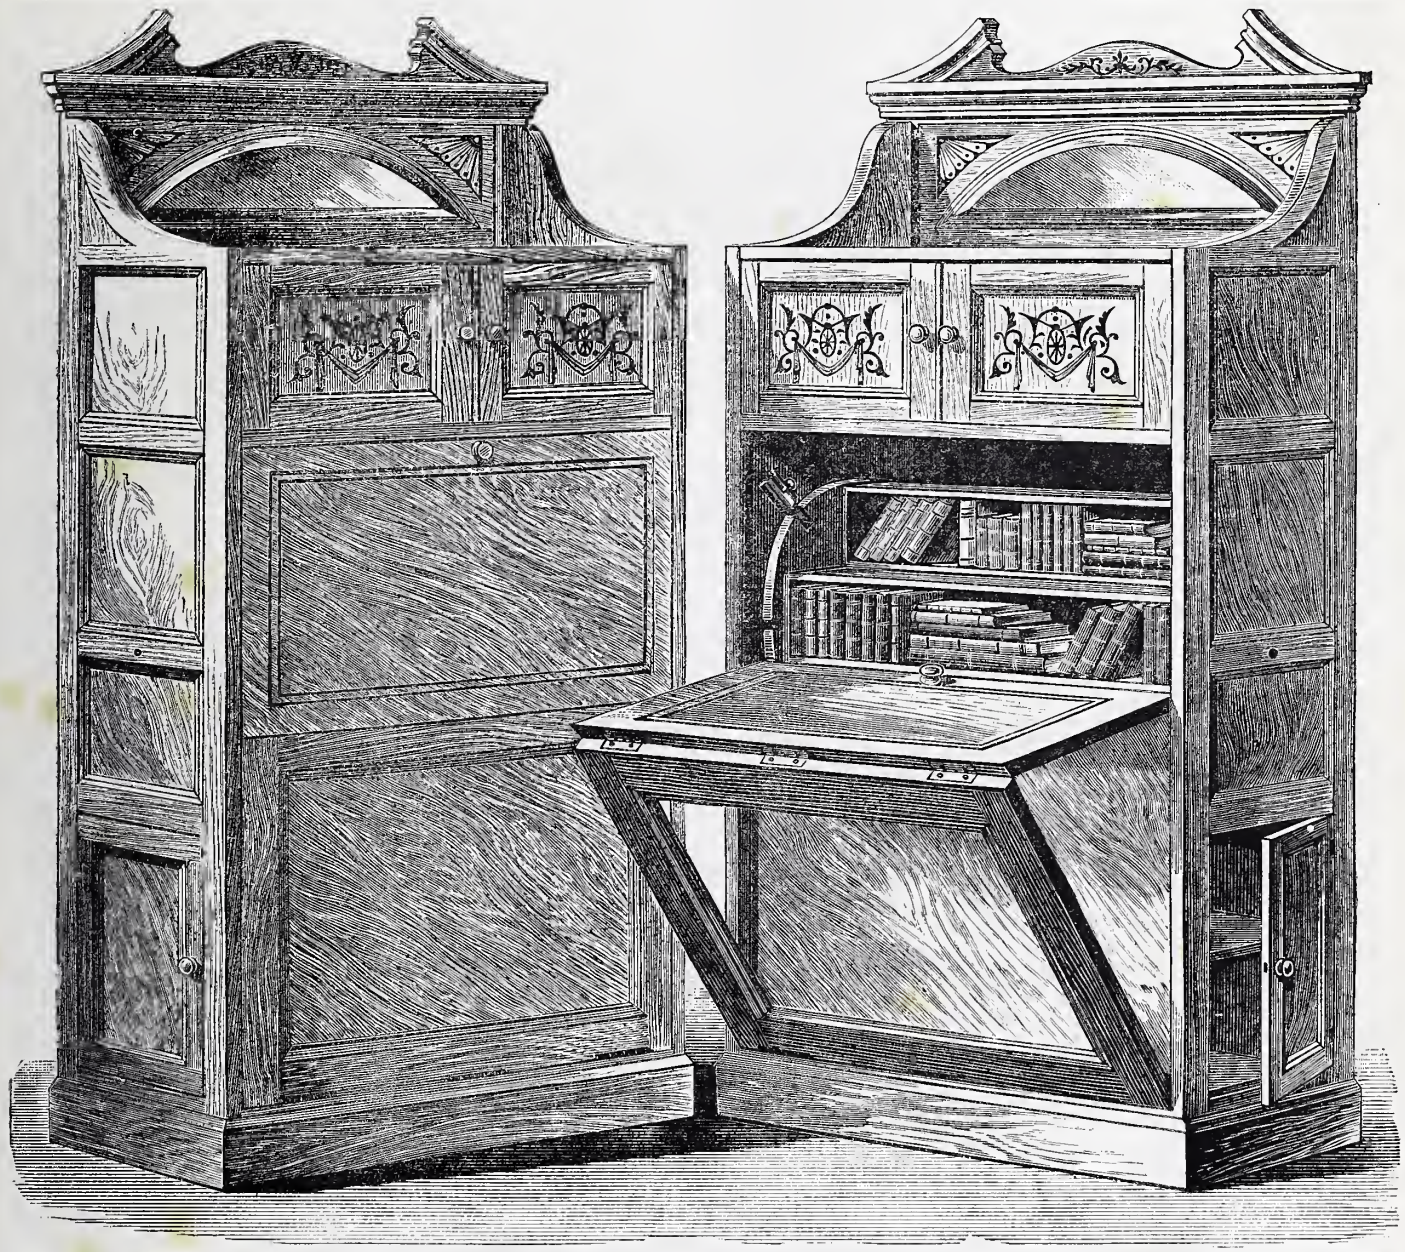

Fig. 1.—Cupboard closed.] [Fig. 2.—Cupboard open.

A WRITING CUPBOARD, WITH ADJUSTABLE WRITING FLAP AND BOOKSHELVES REVOLVING HORIZONTALLY.

## A WRITING CUPBOARD, WITH ADJUSTABLE FLAP AND BOOKCASE REVOLVING HORIZONTALLY.

BY JAMES SCOTT.

Utility of Cupboard—Construction—Bookcase and Book Boxes—Small Cupboard at Top—Plinth—Dimensions and Mode of Making—Backboard—Doors—Pediment—Revolving Bookshelves—Writing Flap—Finishing.

Many a man may find such an article as I have designed for this week a welcome addition to his home. I say "home," because I have specially intended it to be of more service there than in business departments, although in the latter it would certainly be found very useful. In most offices, however, the adjustable writing flap would not have much advantage over the ordinary writing-desk tables, as very few men indeed would like to clear the papers from it every night in order to shut up the cupboard.

But, as before said, in the home it may find a welcome. There are several persons who find it a matter of necessity, or perhaps pleasure, when they are within their homes, to write or study occasionally; and this combined bookcase and writing table, possessing, as it does, a few advantages over

ordinary articles of the kind, will enable them to do so as comfortably and conveniently as possible.

As may be seen by a glance at Figs. 1 and 2, very little trouble will be occasioned to put the article into position for use as a writing table or bookcase. The cupboard has, in front, a flap and a rather wide framing hinged together. In opening the cupboard, the catch at the top of the flap is released, and an arrangement (of which more will be said later on) prevents the top edge of it coming from between the cupboard sides, with the natural result that (the bottom of the lower framing being hinged as in Figs. 1 and 2) the flap is adjusted on the slope, and is adequately supported by the lower framing, etc.

The framing is much to be preferred to a solid board, as there will then be sufficient accommodation for the knees of the person who may be writing at the article.

The other feature of the cupboard, and one that will, I think, be considered a novel and useful one, is that of the bookcase being so made and fixed as *to revolve horizontally*. The advantage of this feature will, perhaps, be readily conceived. A series of boxes, of which one is shown in Fig. 16, all of one size, or of different dimensions (provided, in the latter case, space is properly allotted for their movements), are pivoted between two circular boards, which, in their turn, are pivoted to the sides of the cupboard. A person may be occupied writing at the desk, and find it necessary now and again to make reference to some particular volume or paper in his possession. With the ordinary secretary bookcase, supposing the volume required was on the top shelf, this would necessitate his rising from his seat; and in the present case, with so large a writing flap, this would be found doubly inconvenient; but as the shelves revolve horizontally, the volume can be obtained by turning the boxes until that one in which it is contained comes round to the front.

If all the book boxes are the same size, and are generally proportionately stocked, whenever the hands were taken from the case after revolving it, it would remain steady; but as differently sized boxes may be used, or, if all one sized are made use of, some shelves might be well filled, while others were half empty, I have shown how the case can be kept steady by means of a bolt fitted within the cupboard, which will enter into notches or holes in the edges of the two circular boards at the ends of the case. It will be best to countersink the heads of *all* pivots, so that none of them may interfere with the free revolutions of the boxes.

In Figs. 3, 4, and 5, I have given elevations of three bookcases; in one diagram showing equally sized boxes, and in the other two, boxes of different dimensions. Other sizes may be made, but they will have to be worked out very carefully, for in revolving, unless proper space is allowed for the movements of each box, some will knock one against another. My diagrams are drawn to 1¼ in. scale, and those who understand scales will have no difficulty in finding what size each is intended to be. Here are a few hints, however, for those who do not understand scales, and who, by their ignorance are unable to arrive at any conclusions concerning what, at some time or another, may have been, or shall be, said. If ¾ in. scale is alluded to, all that need be done is to have a narrow piece of card or paper, and from an ordinary rule or measure indicate upon it a sufficient number of spaces, each ¾ in. long, and divide the first space into twelve equal parts. For any other scale, this same method should be followed, of course making each scale the length of the figure given, and always dividing the first space into twelve equal parts, which will represent inches. When a drawing or diagram is said to be drawn to a certain scale, the rule with that scale marked upon it should be used to measure the diagram or drawing, every large space representing a foot, and every small space an inch. These remarks may seem to some unnecessary, but I have personally met with men who have thanked me for the simple information. I shall give the dimensions of the equally sized boxes in due course, but shall leave the others to the reader.

I have represented in my design a small cupboard at the top, which may be found convenient for a good many purposes, but, of course, I need not say that it is not indispensable.

The suggestion of the bookshelves revolving, as shown in the design, may be turned to use separately and apart from the writing table, such as adapting it upon a table within a case, with either one or two doors on one side or on each side.

Sketches of one way of making the plinth are shown in Figs. 10 and 11. The latter represents a top view of it, and the former an under view, showing corner blocks inserted to add to its strength, and also to which castors (if they are required) may be screwed.

Fig. 16.—One of the Hanging Book Boxes.

The length of it will be 46½ in., the width 20 in., the depth 5 in., and thickness of boards, say, ¾ in. To this is screwed the top carcass.

I have intended the sides of the cupboard to be "mock"-panelled—*i.e.*, a whole board with beading mitred and glued on to it; but, of course, with this article, properly panelled sides may be used, as the only boards joining them crossways will be the top and bottom boards and the board forming the bottom of the top cupboard. The shelf at the bottom of the job need only fit loosely on to a ridge screwed inside the cupboard to support it.

The length of the cupboard sides in front will be 62½ in., and at the back 75 in.; the width 18 in.; and the thickness, I think (as the job is really so open), no less than 1½ in. The small doors at the bottom might each be 22 in. long and 15 in. wide.

The top and bottom boards of the article, and the bottom board of the small top cupboard, will each be 42 in. long and 18 in. wide (all my measurements in this paper allow sufficient for joining), and about ⅞ in. thick. The sides are joined together in front at the bottom half of the article by a board 42 in. long, 26 in. wide, and ¾ in. thick. This board will be necessary to form a background for the knee-framing, unless, in place of the latter, a whole board is used, which I certainly do not advise, on account of the inconvenience it will create. The board should be joined at a distance from the edges of the side boards equal to the thickness of the front framing.

I always prefer the back board of an article of this kind to be made as one whole thick board instead of thin matchboard. The height of it should be 62½ in., the top edge of it thus coming flush with the top surface of the top boards.

The doors of the top cupboard will each be 19¾ in. long, 10½ in. wide, and ⅝ in. thick. Panels of, say, ⅜ in. stuff, nicely inlaid, carved, incised, or stencilled, will rob the article of some of its plainness. I have not intended this small cupboard to have a division down its middle; a piece of moulding will be glued on to one of the door edges, as shown by A in Fig. 18.

The pediment and the top back board containing the looking-glass are shown in Figs. 8 and 9. The top edge of the larger back board must be cut to receive the bottom of this part, which should be screwed to the larger back board and to the back edge of each side board. The height from the bottom edge to the top of the straight moulding will be about 15 in.

The revolving bookshelves or boxes now claim attention. Two circular boards, each 18 in. in diameter, and about 1¼ in., or even 1½ in., thick, are pivoted with good, strong pegs to the inside of the job. On the outside these pivots need not show, my sole purpose for showing them in my drawings being merely to indicate their position.

Taking the boxes represented in Fig. 3, the length of them will be 36½ in. or 37 in., according to the thickness of the circular boards, the depth 7 in., the width 6 in., and the thickness of the boards composing them ½ in.; the pivots connecting them with the circular boards being driven through precisely the spots I show, each one being at 2 in. from the edge of the circular boards. When fitted in its proper place, the bookcase will, if equally weighted, as I said before, remain in the position it may be left after turning it round; but a bolt, or something similar, is to be preferred, and whatever is used must work only in the *edge* of the circular boards, and *not on the surface*, as in the latter case it would interfere with the free movements of the boxes, and they would thus become utterly useless. A bolt need only be fitted on one side, unless very heavy books are within the case. It will be fitted as in Fig 12, and the edge of the circular board may be either as in that diagram, *i.e.*, with holes drilled into it, or, as in Fig. 13, with notches. To further support the case, I should advise the screwing to the sides of the article, directly underneath the circular boards, of stout pieces of board, as in Fig. 6.

I should not recommend the fixing of a board underneath the bookcase, other than that shown in Fig. 2, as if one is used, should a book or paper accidentally fall from the boxes, great difficulty would be experienced in getting it up again; whereas, should one fall, if the article is made as I intend it to be, it would lodge upon the lower shelf, and thus be very easy to get at.

I do not say that the present article, so far as the bookshelves are concerned, would be found desirable where it is not necessary to write at the same time as referring to the books; although, after all, little extra trouble would be required to obtain a book by drawing down the flap than would be caused by opening an ordinary bookcase, the extra trouble being that, unless the book wanted was in view, the shelves would have to be turned; but, as before said, this is a decided advantage when sitting at the desk.

Attention must now be given to the writing flap. A very convenient size for it will be 39 in. by 18 in. It will be hinged

to the under framing as shown; which latter might be 26 in. wide, with a moulding round its inner edge. The flap I have represented as having a couple of lines incised round it. Of course, a moulding would be entirely out of the question.

If the flap were lined with ornamented leather, or leather cloth, it would not be found an objectionable feature of the article when closed, and would certainly be better for writing purposes than the bare wooden surface. The thickness of the flap and framing should be about ¾ in.; and here let me add that both will work better if the edges which meet are canted and hinged as in Fig. 15. A neat, strong catch will be required to keep the flap up as in Fig. 1.

A groove must be cut from just underneath the top cupboard to the top edge of the front board, in each side board, as in Fig. 7. Behind the writing flap, at each side near the top edge, will be a peg, as shown in Fig. 17. The protruding end of this peg will be inserted in the groove A A, and it is this that will keep that part of the flap always between the cupboard sides.

I have not provided any place for stationery; but, if considered inconvenient to keep it in one of the revolving boxes, a compartment could be fitted in front between the cupboard sides and under the top cupboard, where it would not interfere with the freedom of the book-boxes.

## A HANGING MUSIC CANTERBURY IN FRETWORK.

BY J. W. GLEESON-WHITE.

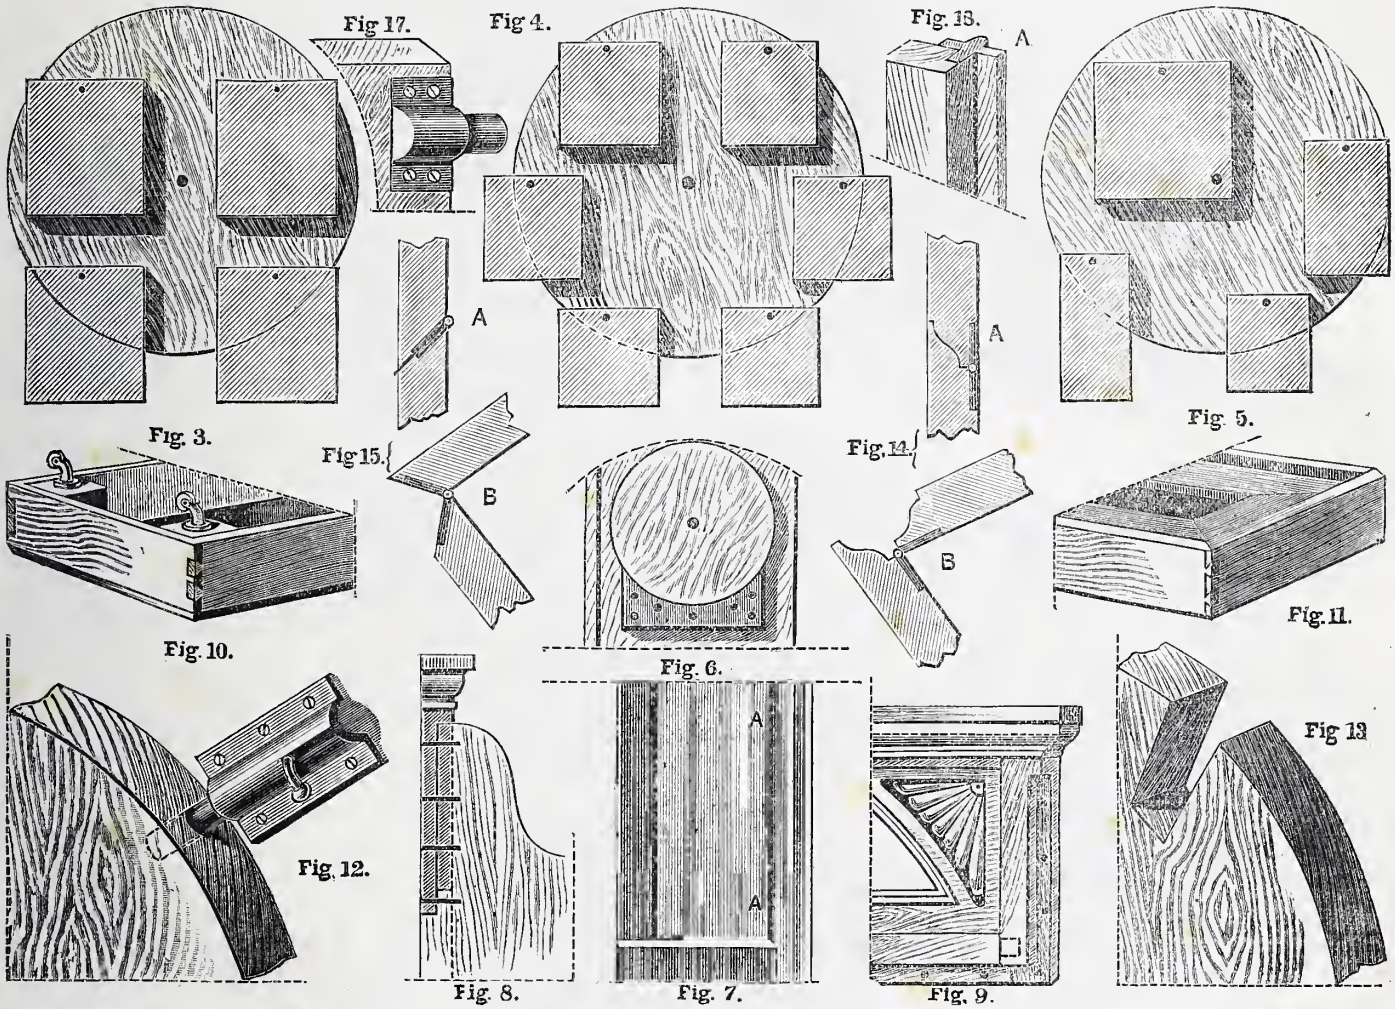
[*For Illustration of Canterbury complete, and Full-size Working Drawings of Parts in Fretwork, see Supplementary Sheet presented with this Number.*]

Why a whatnot with receptacles for music is called a Canterbury it boots not to inquire. Enough that it be so, and that, whilst explaining the meaning of the article to be constructed after the annexed design, it was easier to use the accepted word. Anything less suited for its actual purpose ought to be difficult to parallel, yet, even as Herbert Spencer points out in his first chapter of a "Study of Sociology," it is an unfortunate truth that we all make shift with ineffective but conventional articles, when a little common-sense, or ingenuity of a very mild degree, would fit them for their purpose to a far greater extent.

The orthodox Canterbury does hold a series of bound volumes of folio music in a fairly satisfactory way—that is, if music books must needs repose upon their edges, in a different fashion to ordinary volumes. But our music in daily use (or, at all events, the newest pieces) is seldom, if ever, bound into stiff volumes; and to contain a quantity of sheet music, there is no word to offer in its defence. It is ill adapted for sorting, as the divisions are too capacious; it damages the music, lets in dust, and, above all, the pieces slide under each other in a maddening way too painfully familiar to need description. There are, it is true, Canterburies that take the form of cupboards for music, with duly panelled shelves. These are admirable when the quantity at hand is sufficient to fill them; yet they offer too much space for the average amateur, and too little for the professional or really rabid music lover, who, like his cousin, the bibliomaniac, knows no bounds to the appetite once it is acquired.

The structure herein to be set forth is for the lowest mean average—the possessor of, say, a hundred pieces of sheet music, more or less—and the problem to be solved: required, a conveniently placed receptacle, fitted to keep the music sorted into its several varieties—songs, dance music, pianoforte solos, duets, and so forth—readily accessible, and sightly enough in itself to add to the adornments of the apartment.

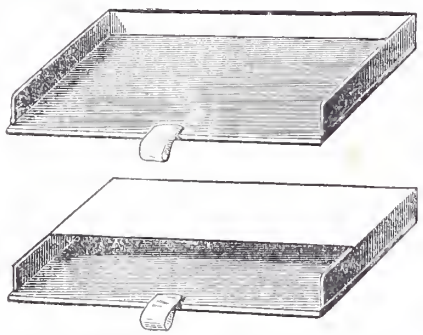
Of all mechanical methods of decorating wood, fretwork is, perhaps, the most general and the least exacting in its demands. No art knowledge is required; patient accuracy in each of its simple stages—in the tracing of the design, the sawing itself, and final polish—will produce work that is, so far as it goes, satisfactory and decorative.



**Figs. 3, 4, 5.—Different sized Book Boxes drawn to 1½ in. scale. Fig. 6.—Wooden Block under End of Circular Board. Fig. 7.—Groove in Side Board. Figs. 8, 9.—Side and Front Elevation respectively of Glass Frame. Figs. 10, 11.—Under and Top Part respectively of Plinth. Fig. 12.—Bolt in connection with Circular Board. Fig. 13.—Notch in Circular Board in place of Hole. Figs. 14, 15.—Two Ways of connecting Writing Flap with Lower Frame—A, Erect; B, in Position to write upon. Fig. 17.—Small Peg behind Flap. Fig. 18.—Moulding on Edge of Door.**

Like humanity, it has its faults—it harbours needless matter in the wrong place; but do not we, physically and mentally? It is spiky, and apt to be intrusive, catching in lace and dusters—easily paralleled in life. It is not so strong as it looks, and has dozens of those failings which an American humorist says he loves, because they make him feel a brother to every man he meets. If you go against its grain, it is short-tempered; if you go with it, it is obtuse; and so an excellent homily of mediæval style, full of laboriously trifling affinities, might be evolved, with some cudgelling of brains, from the much used, yet much abused, minor art dubbed fretwork.

For many reasons, in place of the usual Canterbury, a set of shelves to hang at a convenient height near the piano was thought to be more useful. If a violinist is a member of the family, they would, placed on the wall at a suitable height, support his music desk. In this way, the whole thing becomes a bracket with many shelves, and has space for bric-à-brac on the top one. When artificial light is used, such a place is likely to be more handy than the usual groping in one's own shadow at the ordinary Canterbury.



Trays or Drawers for Music.

Certainly, the old-fashioned article has an enlarged knife-box aspect, as though it were meant to be carried about. But, not to speak of its peripatetic use in crowded thoroughfares—which is absurd—did any one ever meet another so laden? My own notion is that it would break off at the first attempt to lift it from its native floor, while the absurd little quadruped, with its four dumpy legs in the air, would be a funny sight, even if it survived the unusual transit.

But why attempt a crusade against the unprotected and helpless piece of furniture? It is better to leave it to its friends, and introduce its would-be successor.

The weight of sheet music is not trifling. That so ephemeral a thing as the average modern song should be so heavy in bulk is astonishing. Yet, to make good its pretence to be worth two silver shillings, it must needs be on stout paper. Consequently, strength must be the aim, and the fretwork sides which support the whole weight should be cut out of wood—preferably three-ply wood—not less than a $\frac{1}{4}$ inch thick, and of fairly hard quality.

It will be seen that the design is planned so as to take shelves at a very short distance apart. If the size of the whole side piece is too large for the machine, the bracket portions may be cut separately, and fixed below the bottom shelf.

The top railing at the sides and back may also be cut in detached portions and fixed, as the brackets. In this case, the uppermost and lowest shelves should project slightly, and be finished with a moulding round sides and front.

It would greatly facilitate reference to its contents if false drawers or trays, of thin wood or cardboard, covered with cloth, as shown, were fitted to each recess. If preferred, these sham drawers might be developed into actual drawers, bearing each on its front the emblazoned legend of its contents.

But these additions will easily suggest and recommend themselves to workers according to their several needs. For instance, if the suggestion of its serving to support a music desk should be carried out, not only might a fretwork desk adorn its top, but brass candle sconces might be added at its sides.

For choice of wood, bearing in mind that some number of feet are needed, the most economical and effective plan would be to ebonise the whole, and thus allow common deal to be used for the shelves and uncut portions, or at best cheap mahogany.

Aspinall's enamel on fretwork is possible, if great care be taken in rubbing down the surface of the wood, using repeated applications of scalding water; and after each has thoroughly dried, taking off the grain which thereby swells up with fine glass paper, a good surface might be secured, on which the enamel could be used with a really good effect. How far a naturalistic painting of the leaves and fruit forms would be pleasant, I cannot say personally. In one out of a thousand persons who has an instinct for colour, it might be a delightful novelty; but I fear me that the nine hundred and ninety-nine would achieve an egregious failure.

Whatever its shortcomings, it is possible that the completed article will be found as admirable to those who may construct it as it has been to its creator.

## THE VIOLIN: HOW TO MAKE IT.

BY J. W. BRIGGS.

INTRODUCTION—WOOD FOR VARIOUS PARTS—BELLY, BACK, RIBS, NECK AND SCROLL, BASS-BAR, SOUND-POST—BLOCKS—LININGS AND PURFLING—OUTSIDE AND INSIDE MODELS: HOW TO MAKE THEM.

**Introduction.**—A great writer on the subject has divided mankind into two classes—those who play the violin and those who do not. It is almost unnecessary to say that the violinists are in a minority; but if those who do not perform on this instrument continue to encourage those who do, there will be little cause for dissatisfaction.

It is not my purpose in these lessons to attempt to trace the origin of the violin—writers without number have used their pens for this purpose—but the fact remains that the instruments brought to a state of perfection never exceeded, if even equalled, came from the workshops of the Cremonese masters, and have earned for them almost immortal fame. The effectiveness of the violin, when handled by a competent performer, is so obvious that a person must indeed be devoid of all musical feeling who is not influenced thereby.

No matter what the theme—a rollicking jig or a sublime adagio—no instrument better fitted to give expression to the feelings has yet been invented. Its melodious strains may for a time be drowned by the blare of the cornet or the blasts of the trombone. Now and again the liquid notes of the flute or the oboe's plaintive wail may divert the ear of the listener, whilst the full and sweet melody of the clarionet is not to be ignored. The ear, however, soon becomes tired of these, although they add pleasing variety, and it is the violin alone which never becomes monotonous. In the orchestra it reigns supreme. To dwell further on the merits of this most fascinating instrument would only be too easy and congenial, but in a publication like WORK something more practical is

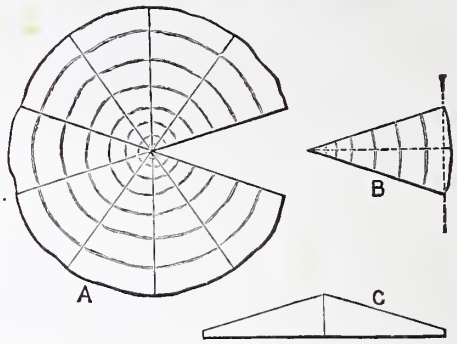


Fig. 1.—A, Section of Sycamore or Pine, cut on the quarter; B, Piece marked for sawing down; C, Ditto, jointed, ready for Use.

required. We will therefore proceed with the construction of our instrument.

It is a matter worthy of consideration that although the science of acoustics has kept pace with other branches of knowledge, the efforts of the great masters have not been improved upon, and the best results have been obtained by following as closely as possible the lines laid down by the Cremonese makers during the seventeenth century. Though opinions differ as to the relative merits of the various outlines and models, I propose to take for granted that the outline, measurements, and *f* holes of "Stradivarius" are the best, and to describe to the best of my ability the methods on which I work, and giving, as occasion requires, all the full-size working drawings, and a short

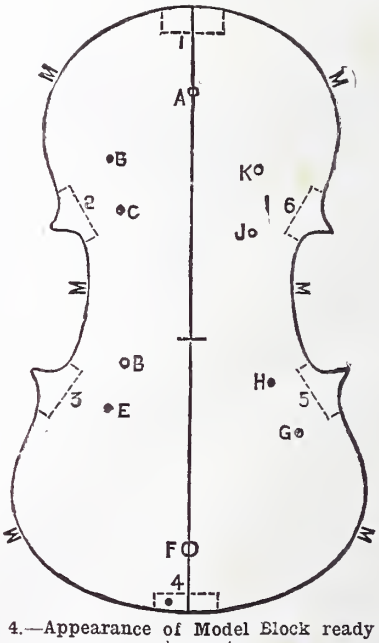

Fig. 4.—Appearance of Model Block ready for sawing out.

description of the tools specially needed when making a violin. I hope, in the pages which follow, to make myself clearly understood; should I fail to do so, it will be a pleasure to me to give, if possible, further explanation on any point which may seem obscure. There must, in dealing with a subject like this in a purely technical way, and free from all romance, be a danger of appearing

tedious; should this occur, I must plead my desire to be explicit as a sufficient excuse.

**Wood for Various Parts.**—It is most essential when setting about making a good violin that you have the very best materials from which to make it. Notwithstanding all the arguments in favour of artificially prepared wood, I am convinced that that which has been naturally seasoned is by far the best, and most likely to improve with age and use.

*Belly.*—For the belly we require a **V** or wedge-shaped block of clean, even-grained Swiss pine, 15 in. long by about 5 in. broad, 2 in. thick at one edge, and tapering to about $\frac{3}{4}$ in. at the other. This block should be cut on the quarter: this mode of cutting is shown in Fig. 1.

This gives the reeds or veins, which are portions of the concentric rings, running vertically through the wood in the direction of its thickness. The same result is also obtained by using the middle board, but in this case the two halves of either back or belly would not necessarily correspond in grain or in figure; and as we are going to work with a half pattern, from a centre line, let us have the wood cut as at B, Fig. 1. It is only when cut on the "quarter" that pine gives the beautiful mottled and silky appearance known as "flower."

The table from which the belly is to be made should, when jointed and planed true (as at C, Fig. 1), be $\frac{5}{8}$ in. thick at the ridge.

Care should be taken when selecting this wedge to see that it has been "riven" or split, so that the fibres have run in their natural direction.

*Back.*—The back is generally of sycamore, cut also on the quarter: the stripes or bars in sycamore show at their best only when cut in this way. These strong bars or waves are termed the "figure." The piece for the back should be 15 in. long, $1\frac{3}{8}$ in. thick at one edge, and about $\frac{5}{8}$ in. at the other. Good back wood is very valuable, and the pieces are therefore cut so fine, that there is very little margin for waste.

*Ribs.*—The "ribs," or sides, are of sycamore, and may easily be purchased in strips, cut for the purpose, 15 or 16 in. long, by $1\frac{3}{8}$ in. broad, and about $\frac{1}{12}$ in. thick. They should not require much cleaning up before being ready for use.

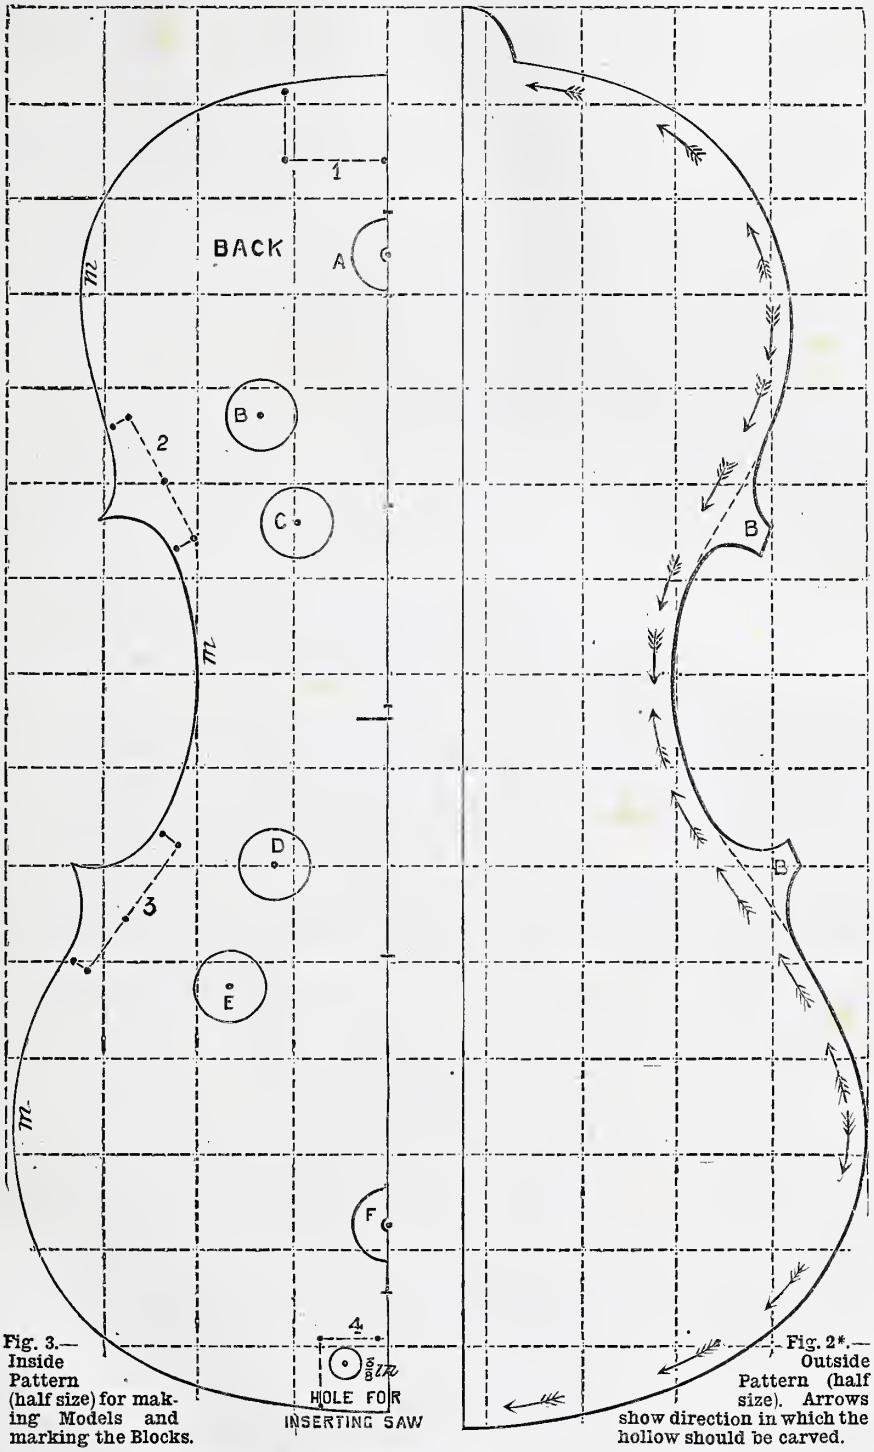

**Fig. 3.—Inside Pattern (half size) for making Models and marking the Blocks.**

**Fig. 2*.—Outside Pattern (half size). Arrows show direction in which the hollow should be carved.**

*Neck and Scroll.*—To carve the scroll is one of the most difficult operations to be encountered when making a violin throughout; and as it greatly beautifies or entirely spoils (as the case may be) the appearance of the whole instrument, I think it would be better for you to buy a neck with the scroll already cut; but as some of my readers may like to try their hand, I shall give, as well as I can, instructions for doing so later on.

*Bass-Bar.*—The bass-bar is one of the most important parts of a violin, and on its dimensions and position depend to a large extent the tone of the lower strings. It is made of similar wood to the belly, and in the rough should measure 11 in. long by $\frac{1}{4}$ in. thick and 1 in. deep, the reeds running vertically through its depth and parallel the whole length of the bar. It should be placed parallel with the joint of the belly, under the left foot of the bridge.

*Sound-Post.* — The sound-post is a round piece of fine-grained Swiss pine, $\frac{1}{4}$ in. diameter, and *about* $2\frac{3}{16}$ in. long. Its proper position (varying as it does in nearly every instrument) is difficult to determine; but it is usually just behind the right foot of the bridge. It should be just long enough to stand firmly before the violin is strung, and the grain should cross that of the belly.

*Blocks.*—These should be made of nice clean pine, an inch thick, from the middle board, if possible, as they will then be on the quarter, and will cut much cleaner. The grain runs vertically from back to belly. They are for affording support to the neck and end pin, for holding the ribs together at the corners, and to strengthen the fiddle generally.

*Linings.*—The twelve pieces of lining are put in to strengthen the ribs, and to give a greater gluing surface for attaching back and belly. They may be made from either pine or sycamore, and are $\frac{1}{16}$ in. thick and $\frac{1}{4}$ in. broad. I much prefer sycamore for linings, as it is not so liable to splinter when necessity arises to have either back or belly removed.

*Purfling.* — Purfling may be bought from violin makers or dealers at about 1d. per foot, and is generally made of two thin strips of wood, dyed black, with a strip of white wood between, the whole being about $\frac{1}{16}$ in. thick and $\frac{1}{12}$ in. deep. Some of the great makers used whalebone for making the black parts of purfling.

**Outside and Inside Models: How to Make Them.**—There are two ways in which a set of violin ribs may be put together: viz., inside an outside model, or outside an inside model. The latter is, I think, much superior to the former, being far handier and safer; but both models may be made from the same piece of wood, and with very little extra trouble. You should procure a piece

* To enable readers to furnish themselves at once with Full-size Working Drawings of all diagrams given half size, as Figs. 2 and 3, such diagrams have been divided into half-inch squares for enlargement on paper divided into inch squares. If any difficulty is experienced in dividing paper into squares for the purpose of making the enlargement, some of Letts's Sectional Paper on the scale required should be purchased.—ED.

of well-seasoned straight hardwood, as beech, birch, or sycamore, 17 in. long by 9½ in. broad at one end, tapering to 8½ in. at the other, and 1⅜ in. thick. Plane this piece perfectly true in length and breadth, and finish it 1$\frac{5}{16}$ in. thick at the broad end, tapered to 1¼ in. at the narrow end. Now make a line down the middle from end to end with a steel marker, or an ordinary bradawl sharpened to a fine point. Afterwards trace the line with lead pencil to make it more legible.

Cut out the patterns Figs. 2 and 3, in zinc or thin wood, taking care to have all the marks on Fig. 3 quite distinct. Place the pattern, Fig. 3 (which in future shall be called the "inside pattern"), exactly to the centre line on the block, and an equal distance from each end, and carefully, but decidedly, trace round the pattern with the marker, following with lead pencil. Then mark through the pattern the position of each block, as shown by the dotted lines in Fig. 3, and also the centres for the holes, A to F. Now turn the pattern over, and mark the other side in precisely the same manner; on the accuracy of this operation the ultimate balance of your fiddle depends. When ready to be sawn out, your block should bear every one of the marks which appear in Fig. 4. With a ⅜ in. bit bore the hole for inserting the saw. The models can now be cut out with a bow saw, but a much better plan is to get it cut at a sawyer's, with a "fret" or a "jigger" saw, making a cut of $\frac{1}{12}$th of an inch, and going exactly round the line, M, M, M, subsequently cutting out the recesses, 1, 2, 3, 4, 5, 6.

The edges of both models should now be trimmed up, which must be done by placing each of the models edgeways in a wood vice, and, using a file, one end in each hand, taking out all the small ridges which the saw has made, still keeping both models square to the side on which the outline was traced. Write distinctly on both models the word *back*: this will avoid much confusion that might otherwise arise. Next, with a ¾ in. bit, bore the holes, A to K. You should now square the centre line down each of the end block recesses 1 and 4, and with a straight-edge make another centre line the entire length of the other side of model. We now have two well-finished models (inside and outside); and before proceeding further, we had better consider the question of what tools we shall require. For this, however, we must wait for the next paper.

## KNOTTING, SPLICING, AND WORKING CORDAGE.

BY LANCELOT L. HASLOPE.

### Introduction.

Antiquity of Art of Knotting—Cordage, to What Applied—Laying Fibres of Rope—Yarns — Strands — Principle of Rope Making—Réaumur's Experiments on Laying up Fibres of Rope—Size of Rope—Calculation of Strain.

The art of knotting has been said to be "probably as old as human fingers," and there is no doubt that mankind must always have used some kind of knot to join the sinews of animals, fibres of plants, or strips of hide that, in ancient days, formed a substitute for the endless variety of cordage in use in the present day. It is needless to enlarge on the importance of a knowledge of knotting, as hardly a day passes, even in private life, but we have to make a knot of some kind; and, of course, to the fisherman and seaman, whether amateur or professional, the subject is one of paramount interest. This being so, it seems strange that so little, comparatively speaking, has been written on the subject. I trust these articles will go far to remedy this defect, and to supply what I believe to be a real want. Even those of my readers who have not much occasion for working cordage will, I think, still find the subject an interesting one. They will be surprised to find what a large number of knots the skill of man has invented, many of them being highly ingenious, and capable of being used in various ways for decorative as well as useful purposes. The importance of being able to make a knot rapidly and correctly, and, at the same time, the one best suited for the purpose for which it is intended, cannot be over-estimated. Human lives, to say nothing of property, have over and over again been sacrificed to ill-made knots, and I believe there are few things of an ordinary kind that will better repay the trouble of learning than how to work cordage successfully.

The generic term cordage comprehends a vast variety of different kinds of rope, from the cable of a man-of-war to the fine "snooding" of the sea fisherman. It is also composed of a great diversity of materials. The most common substances from which it is made are hemp, flax, cotton, manilla, and coir. It is outside our present purpose to go into the process of the manufacture of rope in anything like detail, but the succeeding pages can hardly be fully understood without some knowledge of the construction of cordage; I shall therefore give a few particulars as to the various parts that form a rope.

If the fibres of which a rope is composed were laid parallel to one another and fastened at the two ends, the combined strength of these fibres would be better utilised than by any other means—in other words, they lose strength by being twisted or "laid up." But, on the other hand, the length of the fibres being at most but a few feet, their utility in this state is very limited, to say nothing of the inconvenience of using them in this way. To obviate this difficulty, the fibres are first twisted into "yarns;" these, again, are laid up into "strands," a strand being formed of several yarns; and, finally, three or more strands are formed into a rope. As I have before said, the strength of a rope is diminished by the twisting of the yarns, and this being the case, it is important the yarns should be very carefully laid up, so as to bring an even strain on every part. This should be borne in mind when rope is chosen. It should also not be laid up too hard—that is, it should only have sufficient twist in it to prevent the fibres from being drawn out without breaking; anything more diminishes unnecessarily the strength of the cordage, and should be avoided.

Ropes are generally made of three strands laid right-handed, or "with the sun," as it is termed aboard ship. They are then called "hawser-laid." If they are made of four strands laid right-handed, they are termed "shroud-laid." A cable-laid rope is made of three hawser-laid ropes laid up left-handed; it therefore contains nine strands. It will be seen from the foregoing that the size of a rope is regulated by the quantity of yarns that compose the strands, and not by the number of strands that it contains.

The principle of rope making is very readily shown by holding the ends of a piece of twine or whipcord, about a foot long, in each hand and twisting it so as to increase the lay. If the twine be now slackened by bringing the hands nearer to one another, a loop will first form in the middle of the twine, and it will continue to twist itself up into a compact cord which will not unlay, as the tension to which the strands have been subjected causes friction between them, which holds them together. In other words, the tendency of each part singly to unlay, acting in opposite directions, is the means of keeping them together when joined.

Some very interesting experiments were made by Réaumur, the purposes of which were to ascertain the loss of strength occasioned by laying up the fibres of various substances, one or two of which I shall give.

1. A thread, consisting of 832 fibres of silk, each of which carried 1 dram and 18 grains, broke with a weight of 5 lbs., though the sum of the absolute strength of the fibres is 104 drams, or upwards of 8 lbs. 2 oz.

2. A skein of white thread which bore a weight of 9 lbs., when twisted into a cord of two strands, broke with 16 lbs.

3. Three threads were twisted together, their mean strength being nearly 8 lbs. It broke with 17½ lbs., whereas it should have carried 24 lbs. These experiments abundantly prove that though we gain in convenience and portability by twisting the fibres, we lose greatly in the strength of the resulting rope.

In speaking of the size of a rope, the circumference and not the diameter is alluded to. Thus, a three-inch rope would be less than an inch in diameter.

It is often required to know the amount of strain that we may fairly expect a rope to bear. I therefore give an useful formula for calculating it.

Multiply the circumference of the rope in inches by itself and divide the product by five, and the result will be the number of tons the rope will carry. For example, if the rope be five inches in circumference, $5 \times 5 = 25 \div 5 = 5$, the number of tons the rope will carry.

When the strain that a rope will bear is alluded to, it must be understood that a steady haulage is meant, for if the strain comes suddenly on a rope, as when a weight attached to it is allowed to fall suddenly, its resisting power is greatly diminished. This is easily demonstrated by giving a sudden jerk to a piece of twine, when it will part at once, though all one's strength, steadily applied, fails to break it. Knots always more or less diminish the strength of a rope, particularly when they are badly made; so that where as much strain as the rope will bear is likely to come upon it, care should be taken to use none but the strongest knots. The Alpine Club, in the report issued by them of some experiments made on ropes, recommend for joining two ropes the fisherman's knot, and for loops the fisherman's eye.* Probably these knots will bear as much strain as any.

If we require to know the weight of any description of cordage, we can ascertain it, if hawser or shroud-laid, by multiplying the circumference of the rope in inches by itself and by the length of the rope in fathoms, and dividing by 420; the result will be the weight in cwts. For example, to obtain the weight of a six-inch rope 120 fathoms long, $6 \times 6 = 36 \times 120 = 4{,}320 \div 420$, makes the weight of the rope 10 cwt. 1 qr. 4 lb.

* Illustrations of these knots will be given with subsequent papers, and will be found, the former in Fig. 11, and the latter in Fig. 16.

The rule for cable-laid rope is somewhat different. In this case, multiply the circumference in inches by itself and divide by four; the product will be the weight of the rope in cwts.

In practising knotting it is as well to use a tolerably firm material, such as whipcord, for small common knots, or, still better, small fishing line—of course, I mean line used for sea fishing. Either of these can be tied up and undone over and over again without injury to the stuff, which is not the case with twine; it is also more easy to see which way the parts of a knot lie in the harder material, and then to find out whether the turns are properly made or not. In the case of more complicated knots, particularly those where the strands of the rope have to be unlaid to form the knot, such as a wall knot or a Mathew Walker, I should advise that three strands of fishing line be used, about a foot long each. If a seizing be put round them in the centre, so as to hold them firmly together, we have a good representation of a rope with the strands unlaid ready for working. A knot can be made and unmade as often as required in this way, without the strands suffering any detriment, which is not the case with the strands of a rope, which, from their loose nature, will seldom bear knotting more than once or twice. I have adopted this plan myself with great success in making the illustrations for these articles. If desired, the knots can be made as above described and kept for future reference. In string also it is better to use hard laid stuff at first, but when these matters are thoroughly understood, knots can be made on any sort of cordage without difficulty.

## HOW TO STROP A RAZOR.

BY P. B. H.

A few years ago I could never keep a strop for a longer period than about nine months, as, during that time, it got so cut up that it was, comparatively speaking, worthless. A kindly hint from a friend some five years ago saved me a deal of expense in strops, as, since then, I have used the same one, and there is now only one cut in it, which was made when quite new, just before the hint was given.

As I am certain a few hints on this subject will be useful to some of the many readers of this journal, I shall endeavour to enlighten them by the following description and sketches.

The regular strop is a flat piece of wood about 1½ in. wide by 12 in. long, with a handle cut out at one end. This wood, with the exception of the handle, is covered on both sides with leather about ¼ in. thick. The surface of the leather of the one side, being covered with some sharpening composition, generally flour of emery, is dark. This side should always be kept moist by every now and again adding a drop or two of oil, and, at greater intervals, a little flour of emery, in order to keep up the sharpening properties. The other side is simply of plain smooth leather for finishing off the razor after being sharpened on the first side.

The method of procedure is as follows:—Raise the strop slightly by placing the end on its case (as shown in sketches), or any other convenient object, so that a complete stroke can be given to the razor. Then, with the dark side uppermost, and the razor in the position shown at B in Fig. 1, draw it upwards, and, at the same time, across the surface of the strop till it takes the position C (Fig. 2).

As on the turning of the razor at this point depends whether the strop is cut or not, care should be taken to follow the directions carefully. There is a great

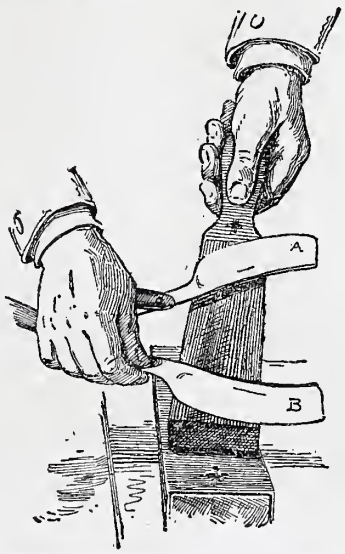

**Fig. 1.—Showing commencement of Down Stroke (A) on Strop, and commencement of Up Stroke (B).**

temptation to lift the razor bodily from the strop at the end of each stroke and turn or reverse it with the cutting edge pointing downwards, which is the principal cause of the strop being cut. The turning should be done at the end of the upward and downward stroke *on the back* of the razor, which should never leave the surface of the strop. During the reversing the razor should be slid sideways on the strop so that the heel rests on it, as at A (Fig. 1), ready

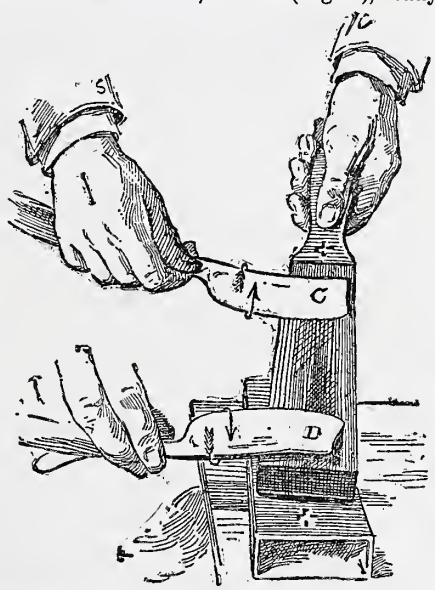

**Fig. 2.—Showing completion of Up Stroke (C) on Strop, and completion of Down Stroke (D).**

for the downward stroke, which is performed as above; the razor at the end taking the position D (Fig. 2), ready for turning in the direction of the arrow, at the same time being pushed forward till it takes the position shown at B, the position from where we started. The blade should never completely leave the strop. After a few strokes upwards and downwards, the strop should be reversed, and the same process performed on the smooth side, when the razor should now be found fit for use. The razor should be held perfectly flat on the strop during the operation. Another great point, in keeping a razor in good condition, is to dry it well with a towel immediately after use, and then draw it a few times over the smooth side of the strop. This takes off any moisture before putting it away. On every good strop and case there is some distinguishing mark to show which way the strop should be put back. I have shown a cross in my sketches. Care should be taken that these two marks always coincide—that is, that the dark side of strop, when put in the case, always touches the one side; otherwise the clean smooth surface of the strop will get emery on it, which will be very detrimental.

## WIRE-WORK IN ALL ITS BRANCHES.

BY JAMES SCOTT.

### Introductory—Crimping and its Inventor.

By the courtesy and practical knowledge of a particular friend, I am in a position to lay before my readers details of a trade different and distinct from that which for many months past I have been permitted to represent.

As most of my readers will doubtless be aware, I have striven my best to give them designs of folding and combination furniture, which, in many cases, I am glad to understand, have met with approval. In making public these designs I have not tendered any excuse for my conduct, nor attempted to defend myself against the friendly, yet unpleasant, accusations of trade acquaintances, who have made remarks to the effect that I have been influencing the trade in a wrong direction, for a certain extent, by giving these designs to the amateur; for the designs being original, I asked neither any body or any thing, except my own conscience, as to what purposes I should place them to; and I have no cause to regret that, with the permission of the Editor, I have given them to the readers of Work.

But as I am entering upon the description of a trade, for correct particulars of which I must rely upon and be indebted to my above-mentioned practical friend, I feel that I must say a few words upon this question of amateur *v.* professional. My worthy fellow contributor, Mr. Clarkson, has mentioned in his articles upon "Bookbinding" (see page 69, No. 57, Vol. II.) that these two classes will never clash, and I firmly believe that as *classes* they never will; but it is an undeniable fact that in many instances members of one or other of these two classes look with contempt, distrust, and very often, I regret to say, hatred, upon the members of the opposite class.

This should not be. Work is a magazine which has been established for the benefit of both bodies, and I am pleased to believe that, through its instrumentality, each body is beginning—in fact, has already begun—to look with a friendly and favourable eye upon the other body.

It is rather late for me to make these remarks concerning Work's mission, but, as I before hinted, I have never taken the opportunity of saying anything of this nature before, for the simple reason that such might have been construed into an

excuse on my part for giving designs to the amateur in my professional capacity.

As an illustration of the harmlessness of the average amateur, I will take an instance from the articles I propose giving under the title of "Wire-Work." Let us suppose I have placed these details before the readers in a plain, straightforward, under-

Fig. 1.—Wire as crimped in Machine.

standable manner (and I am sincere in saying that I trust I shall do so), and that an amateur has grasped sufficient instruction to enable him to make, say, a pair of wire baskets for himself, and that he has decided to make them. Will he not require the material preparatory to the making of the baskets? and will he not have to purchase that material from the wire trade? Certainly. Then whence comes the supposed detriment this inoffensive amateur has created? "Why, from the fact that he is about to make

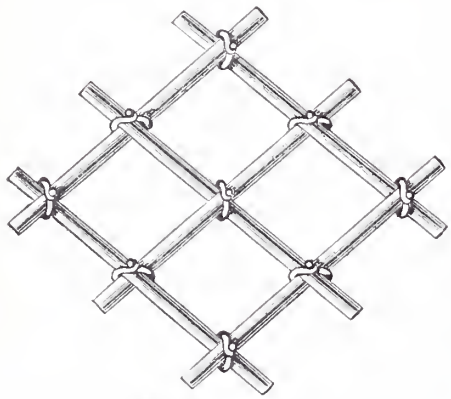

Fig. 2.—Old Method of making Wire Trellis.

articles which he should purchase already made, and thereby encourage industry," I fancy I can hear some disgusted wire-worker murmur.

Now, what does encouraging industry mean? I hide behind common-sense when I say that if people buy what they *want* they are pleasing themselves, and have not the encouragement of industry as their motive. But if they purchase what they do not particularly require, but *may* make *use* of, then they *are* encouraging industry.

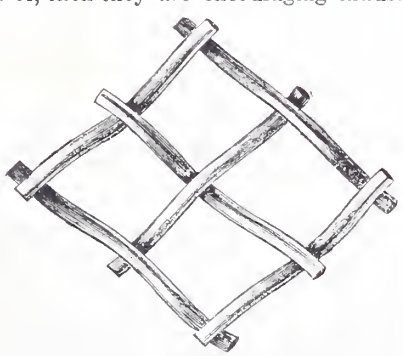

Fig. 3.—Formation of Trellis with crimped Wire.

But this practice is no more to be commended as a stimulus to trade than the purchase of goods at a bazaar—both are but species of charity.

Now, it is a fact that the amateur I am taking as an example may never have dreamt of having a pair of baskets previous to reading my article upon that subject, although he may have seen hundreds during his lifetime; he may make them because he finds pleasure in such work, but when he has made them and exhausted the pleasure of so doing, he will not destroy them, but will find further pleasure in their possession.

The result, then, is that the much abused amateur does not harm any trade he may select to work occasionally at, but, on the contrary, does good to it—very little, perhaps, but still the fact remains.

Then, am I only going to give these details in order that, perhaps, a few amateurs may gain sufficient insight to enable them to while away an hour or so now and again? I don't know. What blissful ignorance! I am going to tell my readers all that my friend tells me and explains to me by experimental lessons. I do not suppose the professional wire-worker to gain much benefit, but I do hope that young beginners in this trade will find my remarks of assistance, as being supplementary to their master's instructions; and I do also hope that many amateurs may experience pleasure from this trade as well as from others.

Many who are in the Birmingham wire trade will remember with respect the name of Mr. Thomas Bellamy, who quitted this life some years back, and who was the inventor and patentee of the crimped or corrugated wire now so extensively used in many branches of wire-working.

His invention consisted of crimping, by aid of machinery, wire intended to be placed together to form fences, garden borders, hen coops, fire guards, etc. The old method of making such things was that of placing the wires over and under each other, and then securing them at their junctions by means of tying with pieces of wire. The amount of labour this process entailed can be imagined by the examination of a piece of work so made, or "put together," as it is technically termed. To simplify matters, Mr. Bellamy stirred his inventive faculties, with the result that he was deservedly enabled to considerably increase his business and his fortune by patenting his ideas.

One end of a coil of straight wire (this sentence sounds somewhat paradoxical and Irish, but my meaning will be conveyed)—one end was put in his machine and drawn through it, coming out at the other side crimped as shown in Fig. 1 and various other diagrams. This was then cut up into the required lengths, which when put together across each other in the same way as the old method, were held together by their own unison, requiring no ties at the junctions, as did the former pattern. After being fitted into their frames, they were as firm and more artistic (if I may be permitted to use the expression in this direction) than were the straight wires. The amount of labour saved by this invention was simply enormous. Whether this fact was beneficial to the trade workers or no I will not venture to discuss, but, in the belief of a notable theologian, who wrote to that effect some time ago in a weekly magazine (which I will not name, for fear of being accused of attempting to advertise), machines are commendable in every trade, by reason of *creating* labour in the particular trades wherein they are introduced, and also in others. In Figs. 2 and 3 are shown the old method and the crimping method respectively.

Various members of Mr. Bellamy's family are still in the same trade, although they have left their native town and are scattered in different directions, and it is to one member to whom I am indebted for my present facilities of giving the following instructions.

I shall arrange the descriptions under two heads—viz., "Plain and ornamental wire-work," and "Wire-work in conjunction with metal mouldings and wood." The first part shall contain explanatory details of the construction of such articles as fire guards, pea guards, rat traps, fences, hen coops, baskets, gas globes, etc., which are composed solely of wire and iron rods; while the latter part will consist of the descriptions of such things as cages, sieves, dish covers, fenders, etc., with which metal mouldings and wood are usually connected.

## FIXING TOPS OF TABLES.

BY H. HINGE.

In making tables for kitchen, dining-room, and all kinds that have any size about them, it very often happens, after all precautions have been taken with the wood that forms the top, in a little while the joints break and open, and what was once a good job now becomes an unsightly thing. The cause of this disaster, of course, is the wood not being dry. What is dry? It has been proved by experience that wood which has been cut years and jointed to form a large top, when it has been in a warm kitchen it has

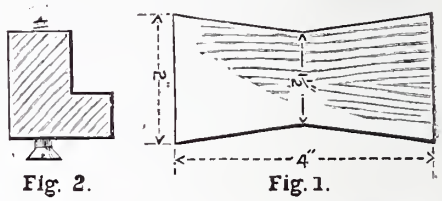

Fig. 2. Fig. 1.

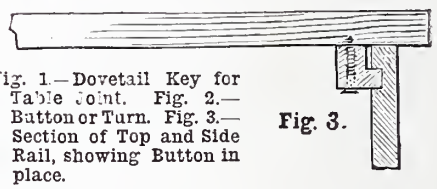

Fig. 1.—Dovetail Key for Table Joint. Fig. 2.—Button or Turn. Fig. 3.—Section of Top and Side Rail, showing Button in place.

Fig. 3.

"gone," the workman has been blamed, and the wood called anything but good. Different ways have been tried both in jointing and fixing the top on, but the following method is one which will allow a top to shrink or go any way without breaking the joints or the top becoming unlevel:—Before the table is framed together, get the rails which go into the legs, and placing them on your bench top edge towards you, inside up, with a plough and $\frac{3}{8}$ in. iron, cut a groove from end to end. There should be about $\frac{3}{4}$ in. of wood clear on the top edge before the groove commences. Serve all your rails like this (if you have any drawer rails in your table, you will see they can be done the same way); frame your table up in the usual way, prepare your top by slip-jointing it, and if you want a really good job put in three dovetail keys in each joint. Those who do not know what a keyed joint is may learn that it is made in the following way:—The joint is made first by planing the edge of the board straight and true till it fits close to its fellow board; it is then glued with good *hot thin* glue, and well rubbed to get the glue out and get it close. After having stood, say ten hours, to set, some keys are made out of $\frac{3}{8}$ or $\frac{1}{2}$ in. oak or mahogany, say 4 in. long, shape of Fig. 1. One of these is then "let in" flush with the top on the under side about 4 in. from the end. Of course, they should fit well on the sides, but a little liberty at the ends is preferable. These are glued in, and when dry, levelled off; in long joints it is necessary to

put in three, four, or five, according to length of top. It is generally acknowledged that this is the best joint for woodwork where practical, having the advantage over all joints which are dowelled or tongued, it being so much easier to get a good close joint. To fasten on the table-top, make, say a dozen, hardwood buttons or turns (Fig. 2). These should be made 1½ in. long out of 1 in. stuff, and notched so that they will fit in grooves in the rails, and room left for a screw to go through into the top. When fixed, which is done by placing the table-top on your bench under side up and putting the frame on the top of it legs up, and placing your buttons into the grooves, send a screw through the other end. Fig. 3 is a section of the side rail, showing the button in its place. It will easily be seen that a top fastened down in this manner can move along the grooves as the wood dries without either warping or breaking the joints and still be fastened down. This method will commend itself at once for many things which require to be held firm and yet allow the wood to shrink for amateur and all kinds of workmen.

*** *The different parts are similarly lettered in each Fig. to show their identity.*

## A NEW MITREING AND SQUARING MACHINE.

BY A "CONSULTING ENGINEER."

I HAVE lately had the opportunity of inspecting a very simple and efficient machine for the above purposes, which has been invented by Mr. Wm. Hutchens, of Penzance, who has applied for and obtained a patent for the same.

The machine consists of a metal bed or sole plate, which supports and carries the working parts and the material to be operated upon, and which is, or may be, placed or supported on a suitable stand at the height most convenient for performing the work. The working parts consist of a movable plane or part of metal or other suitable material, which works on the bed or sole plate over a guide or groove formed therein, which is so arranged by means of suitable cutters as to cut or plane whilst moving in either direction. The cutters are provided with suitable means for regulating and adjusting the depth of cut, and readily removing and replacing them for sharpening or other purposes. On the under side of the moving part to which the cutters are attached a toothed rack is formed, into which a toothed sector or pinion wheel gears. This sector or pinion works on a short horizontal shaft or stud, to which a partially rotating or vibrating movement is given by means of an adjustable lever, and a projecting part or parts on the under side of the part containing the cutters fits into the groove or guide, and so keeps it, when in motion, in the proper position to do the work.

On and to the bed or sole plate is placed and attached the adjustable guide or fence which regulates the angle or bevel at which the material is to be cut, and by means of set screws it may be adjusted and firmly held in the required position.

In the accompanying engraving, Fig. 1 is the plan, Fig. 2 a front sectional elevation on the line *a b*, and Fig. 3 an end elevation, the like parts in each being denoted by the same letters of reference in each Fig.; A A is the bed or sole plate; B, the movable part containing the cutters and arrangements for fixing and adjusting the same, shown where the upper part is broken off; D, the adjustable fence or guide, and the screws, $C^1$, $C^2$, $C^3$, for holding and adjusting the same, which, when set square with the face of the plane or moving part, enables the ends to be squared; E, the groove or guide in which the projections or parts on the plane, or part B, work; F, F, the separate parts, projections, or pieces which work in the groove or guide E, and the screws *f*, *f*, which hold the same in place; G, in Fig. 2, shows the rack on the under side of B, into which the pinion quadrant or sector H gears; I, the horizontal shaft or stud on which the part H is attached; K, socket on end of shaft through which the adjustable lever L passes, and is fixed by the set screw M. The adjustable counterweight and set screw are shown at N in Fig. 3. The parts on which part of the arrangements connected with the cutters work are shown at O, O in Figs. 2 and 3.

By the use of this machine, mitres of 10 in. by 5 in. have been shot with the greatest ease, and it will work on the smallest sizes of material with as much facility as on the larger. It is made in several sizes, to suit the demands of customers, and has been awarded two silver medals at the Falmouth and other exhibitions in the West. The prices, complete, are very moderate, and vary from £5 10s. each, according to the sizes of the machine. It is so arranged that narrower or wider irons may be used in each machine, and it can be seen and tested at Messrs. Engert and Co.'s Picture Frame and Moulding Factory, 75, City Road, London, E.C. I can safely say that it is such a machine as ought to be in every workshop where mitreing of any kind has to be done, as it will quickly repay its cost by the superiority of the work done and the speed and convenience with which it may be carried out. Its utility is obvious, and without doubt it will very soon come into general use.

## HOW TO FRENCH POLISH.

BY DAVID DENNING.

FULL directions for polishing furniture and other woodwork by means of waxing and oiling having been already given, no doubt there are many readers who will welcome the appearance of directions for the more difficult process of French polishing, by means of which the highest possible gloss may be given to suitably prepared wood. At the outset, let it be said, for the benefit of some, that varnishing and French polishing are by no means the same. The one can be done by any person with little or no practice, and is not suitable for any but the commonest articles of furniture, the other cannot be done properly without considerable practice and care; but when skilfully

managed, it enhances the beauty of nearly all kinds of wood. If badly done, it is often rather a blemish than otherwise, so that the beginner, if he be wise, will not attempt to polish anything of value till he has gained some little experience by practising with comparatively unimportant articles. I do not want to discourage amateurs and novices, but it would be only a false kindness to tell them that they can at once proceed to polish well by attending to instructions. However clearly these are given, they cannot give the knack and experience, which can only be gained by practice. Many beginners, I am aware, labour under the mistake of supposing, because they cannot get the same beautiful polish that is seen on the best furniture, that there is something wrong, either with the stuff they are using, or with their method. Without saying that one or the other, or perhaps both, might not be capable of improvement, the defects are probably principally owing to want of practice. The disappointment, no doubt, is somewhat emphasised by having noticed the easy—not to say lazy and seemingly effortless—way in which an experienced polisher brings up the brilliant even gloss. As a matter of fact, French polishing, like playing the fiddle, is not difficult when the knack has been acquired; but this cannot be got at once. The actual directions may no doubt help towards success; but they are unable to do more, and though every effort will be made by the writer to omit nothing of importance, it is quite impossible to foresee every trifling difficulty which individual readers may encounter.

To a certain extent, the polisher's calling has, perhaps, suffered in the hands of amateurs and novices, who have not had opportunities of learning in a practical workshop by the amount of mystery which sometimes seems to enshroud it. To practical polishers, the complicated recipes for stains, polishes, etc., which are often published for the benefit of the amateur seeking information, are a cause of wonderment. They are among the things not generally known in the workshop, but as many of them are elsewhere vouched for, they may be admitted on due report of being useful somewhere.

The ingredients of the various preparations are generally few and simple, and success certainly does not necessarily lie in complication and multiplicity of mixtures.

Although it may be said that, roughly speaking, each kind of timber requires different treatment, the general manipulation is very similar for all. In the main, it consists of coating the wood with a thin film of shellac, either pure or in mixture with other gums and resins, and getting a gloss on the film as brilliant and durable as possible. Before this can be done the wood generally has to be prepared, and various other minor details attended to. For example, the grain, or rather the pores, of open grained wood must be stopped, or, as is generally said, filled, to get a perfectly smooth surface, and to prevent the excessive absorption of the liquid polish. Then there are some woods the appearance of which is improved and enriched by oiling them before applying the polish. This, to a certain extent, darkens them, giving a mellow look, and, as is said, brings up the figure. The different treatment of the ordinary furniture woods will be named in the course of future papers; at present only general treatment can be dealt with. The place in which French polishing is done, or rather the temperature and atmosphere of the place, are of considerable importance. The work cannot be done properly in a cold damp room or outhouse. Warmth especially is absolutely necessary, so that a room which will do well enough for ordinary manual work may not do for a polishing shop. If the place is too cold, the polish as it sets on the wood gets chilled, and becomes more or less opaque and cloudy-looking. Slight chill may, to a certain extent, be cured, but the best way is to avoid it altogether by working in a warm room. By way of forestalling possible inquiries addressed to "Shop," I may as well say that I cannot tell what the minimum temperature should be, and I expect very few polishers could. As a rough guide, it may be said that an ordinarily comfortable temperature of a living room is about the thing. During warm summer weather a fire is not necessary, in the winter time it is. For the rest, if the polisher notices that his polish "chills," he must increase the heat of his room. As chill will sometimes happen in the best regulated shops, it may be satisfactory to know that if as soon as it is observed a moderate amount of warmth be brought near the surface the chill will probably disappear almost directly. A small article, of course, may be taken to the fire, but with anything large this course would naturally be inconvenient. A good plan in such cases is to hold something warm a short distance from the chilled surface, but on no account must it be allowed to touch, or the heat be great enough to burn, the polish. A common plan, but not altogether a good one, for obvious reasons, is to hold a piece of burning paper near the chill. Another cause of chill is from the article being polished being too cold or damp. It is, therefore, always necessary to make sure when a stain has been used that the wood has become thoroughly dry. It may be suggested that an ordinary flat iron is very useful for small patches or local chills.

Not less important is the employment of suitable materials both in the polish and in what, for want of a better word, may be called the tools of the polisher's art. These latter are of the simplest possible description, and consist almost entirely of wadding or cotton wool and soft linen or cotton rags from which the rubbers to apply the polish are made, and a few bottles, etc., to keep the various polishes, stains, and their ingredients in. The exigencies of space, however, require that consideration of these and other matters must be left to a future occasion.

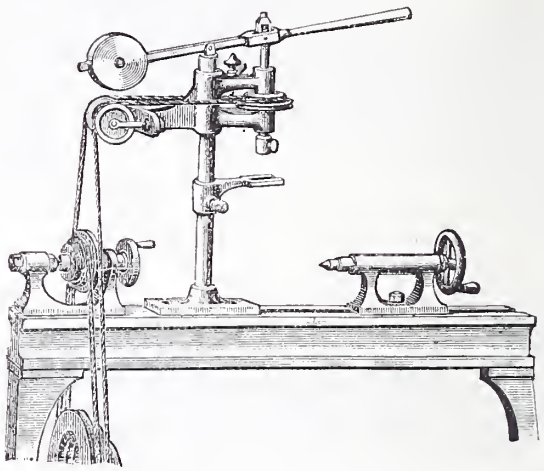
## OUR GUIDE TO GOOD THINGS.

*** *Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

### 1.—The Britannia Company's Lathe Drilling Machine.

My attention has lately been drawn to the Britannia Company's Lathe Drilling Machine, and it seems to be such a handy appliance, and so desirable an aequisition for everyone who owns a lathe, that I think it well worth while to make special mention of it here. The Britannia Company supply several kinds of drills, well calculated for the performance of all kinds of work, heavy and light; but this, as far as I am aware, is the only one which they manufaeture as a special adjunct to the lathe. Its eonstruction, and the manner in which it is fixed on the lathe and driven by the lathe treadle, as well as the manner in which the drill is held and actuated, and the object to be drilled presented to the drill point, are all so clearly shown in the accompanying illustration, that there is really no occasion for me to deseribe them in detail. All that need be said now is that it can be used on any sized lathe, which is a desidcratum, and driven either from below, if for a treadle lathe, or from an overhead pulley. The price of the machine for lathes up to 6 in. centre is £2 2s. Those who utilise the lathe as a motive power for fret sawing should buy this maehine.

Doubtless many a reader of Work, who possesses the Britannia Company's well compiled and effeetively illustrated Catalogue of Engineers' Tools, Amateur Lathes, etc., supplied, the larger one at 1s., and the smaller one at 6d., will have felt some surprise when he has noted the large number of machines and appliances of



**The Britannia Company's Lathe Drilling Machine.**

various kinds that are manufactured and sold by the Company, many of them—especially the lathes, planing machines, and shaping machines—being of enormous size and power, and well-nigh of boundless capacity. And more than this, he must have thought, if he thought at all, that a Company which turned out such powerful and heavy engineers' tools and machines as these, so numerous and so constantly improved and improving that they are known, like eonviets—I trust the Company will forgive the simile—by numbers and not by names, must be one of considerable importance, possessed of large, well-equipped workshops, endowed and backed with almost inexhaustible resources, and finding daily bread for a very large number of hands. My anticipations in these directions were in no way disappointed when I visited Colchester not long since for the purpose of looking over the Britannia Company's works, at the invitation of the courteous and energetic manager, Mr. T. M. Bear, who is at onee the mainspring and motive power of the whole affair. Nothing but a personal inspection is suffieient to show the magnitude and extent of tho work turned out in the Company's extensive and well-ordered factories, in which are to be seen immense workshops, densely, but not inconveniently, oecupied with a variety of machines in motion—one, a screw-cutting maehine, stretching over the whole width of the principal workshop—fashioning, shaping, planing, and cutting the different parts of the numerous machines on order with a rapidity and ease that would appear simply wonderful to anyone unaccustomed to their action. Indeed, one might say that some hundredweights of iron

introduced at one end of the factory comes out a finished machine at the other. I regret that space fails me to speak more at length of the special machines manufactured there, and the handsome, well-lighted, and capacious drawing-rooms, pattern-rooms, and other necessary offices attached to the workshops. One thing, however, I am bound to mention; and that is the order which prevailed throughout the factory, and the attention every man paid to his work, apparently taking the utmost interest in what he was doing, and in looking to the machine that was working under his care. When scattered here and there among the machines, the hands in the employ of the Company did not appear to be very numerous; but this idea, as far as I was concerned, was soon wiped out when the dinner-hour came, and the bell gave the signal to cease work, and from 150 to 200 men soon gathered from all parts of the workshops, and poured out through the factory gates, without crowding and without undue noise, about three abreast, in a continuous stream, which kept going for some time before the factory was left to the manager and myself, and a dead silence followed, which offered a marked and marvellous contrast to the busy hum of active workers and moving machinery that had prevailed a few minutes before.

### A Corner for Those who Want to Talk It.

*** *In consequence of the great pressure upon the "Shop" columns of* WORK, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* WORK *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### I.—Letters from Correspondents.

**On Learning Marbling.**—F. P. (*Newport*) writes:—"Can you spare me space in which to reply to our friend's (R. A. D.) letter upon the above subject, appearing in page 175 of Vol. II.? My answer to W. H., therein alluded to, is condemned as 'bad advice' by one who, from the general tone of his, nevertheless useful, letter believes himself competent to write thereon. The pith of both W. H.'s query and answer in 'Shop' referred to the *cost* of learning. The *practical* value of all that has heretofore appeared in WORK upon any subject few will question, and the 'value for money' aspect of this wonderful weekly pennyworth needs no consideration. Time again will show how far the writer was justified in allocating to a future series of papers the premier position for '*small cost* and practical usefulness.' Respecting, however, the definite courses that were suggested to the learner, I would ask, Does not 'a clever marbler' imply a capable, experienced, and trained craftsman? If it does not, to the thinking of friend R. A. D., surely he is unfair (doubtless unintentionally) to the writer in inferring and construing the same to mean an *incompetent* worker—one who pretends to imitate that which he has never seen, much less studied; in short, any poor craftsman, down to the paper-stainer's boy, who marbles sixpenny sienna (?) at the rate of some 36 feet by 21 in. per minute! F. P. would give place to no reader of WORK in impressing the necessity of studying from Nature; but the 'matter-of-fact' side and technical aspect must not be overlooked. Is not the name of any great art-worker usually connected with his master? 'Nature' can scarcely be expected to teach an individual how to handle his brushes and tools, and what are the nature, properties, and values of his pigments and vehicles. Carry the inquiry still further, and let me give a definite instance:—I have a friend who is sufficiently an artist (unprofessional) in water-colours to have his work hung at the Academy. Surely we might say such an one can only now learn from Nature! My friend thinks otherwise, since he cheerfully pays a half-guinea to watch a professional master paint for an hour an imaginary landscape or a study of foliage. If there is sense in this action, surely a clever master is no danger to a would-be marbler; and I venture to assert, had R. A. D. been so fortunate as to be the pupil of a clever marbler like Mr. Moxon, Mr. Kershaw, or the late Tom Nichol, in more Northern latitudes, be would be a far better *practical* marbler than he is now—however able he may be. I am honestly obliged to my critic for reminding me of the *translation* of Van der Burg's work; and his information *re* the Technical School justifies his writing. I will only humbly endeavour to offer him some useful information in return. A prominent literary worker and marbler (from 'Nature') of forty years' experience gives an authoritative opinion of the above work, worth quoting as against the patronising laudation of R. A. D.:—'There is a Dutch work, price £2 10s., in which *some of the specimens are fairly good* (my italics), but the letterpress instructions are difficult to follow out, being a translation from the Dutch.' Now a few final queries for my critical friend. If this Dutch work is valuable and worth following, as he says, would not the *personal* instructions of either of the brothers—doubtless 'clever marblers'—be of more value? If there is only 'one class of its kind in the United Kingdom' for the would-be marbler to study at, and that in Kennington Park Road, what are all the poor provincials to do? Can they go into the streets and lanes to study rouge roi, jasper, and porphyry from 'Nature'? And if they could, would not there be *something* still to learn about the manipulation of tools, colours, and the varnishing, felting, and polishing? There are two other good collections also worth mentioning of natural specimens—the Geological Museum in Jermyn Street, London (Marbles), and the Royal Botanical Gardens at Kew (Woods), so that the 'City and Guilds, etc.,' very fine collection (all honour to it, however) is not quite alone in its magnificence. Let me here ask R. A. D., and all other earnest believers in work of any kind, to give the contributors of this paper a 'fair hearing,' or rather reading. Surely R. A. D. could count upon the publication of useful information without misconstruing and wrongly characterising so practical and common-sense an answer as, I believe, I have shown to be that which he condemns as 'bad advice.' If 'marbling' is ever to become as popular again, as a decorative feature in buildings, as it was thirty years ago, I venture to opine that it will not be due to the marble studies and paintings of L. Alma Tadema, and such other gentlemen who may spend time *ad lib.* copying pieces of marble upon paper, etc., at the 'Kennington Park Road' class (excellent imitations although they may be), but rather will it be due to those workers who can apply their imitative faculties in a *practical* manner, and offer, not solely minute and slavish imitations, but as much *natural effect* of colour and figure as the very primary and ever-present considerations of cost and comparative values will allow."

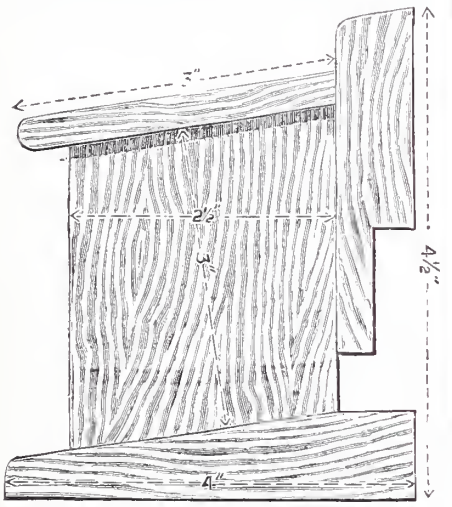
**Home-Made Joiners' and Blacksmiths' Lathe.** Fig. 1.—General View of Lathe. Fig. 2.—B, Plan of Heads; X, Section of Cast-Iron Plates. Fig. 3.—A, Elevation of Front Headstock with Section of Bed.

**Home-Made Joiners' and Blacksmiths' Lathe.**—PRACTICAL JOINER writes:—"Having been a subscriber to WORK since its commencement, I have noticed many inquiries regarding lathes, their construction, etc., especially home-made ones. I have copied one in our shop, made by my father, and which has been in use exactly sixty years. It is drawn in perspective—perhaps not very perfectly, I never having learnt that branch of drawing. I trust my fellow-workmen will be able to understand it. The maker was a joiner in a country village, with, I must confess, a talent for fitting. The lathe is 10 in.; centres partly wood, partly cast iron; the bed is of hardwood plank, 8 in. by 3 in., with a cast-iron top nicely planed, and fitted to the top of wooden bed. This makes an excellent job. The poppet slips beautifully along it. The fixed heads are also wood and iron, the end standard being carried up high enough to form the back bearing; the front ones checked in between the two planks, and a piece of dry wood fitted nicely in between the two, and bolted together, making the whole perfectly rigid and steady. The sliding head is of cast iron, and is the most difficult part to construct. This head was bored out with a flat boring bar, with a piece of half-round wood at the back; after each cut, a piece of thickish paper is put in between the wood, and on the bar, and so on. I bored a small engine cylinder with this same tool, and succeeded perfectly. The mandrel runs in brass bearings; these brasses are fitted into cast-iron plates, the front of which is seen on elevation at A, Fig. 3 (end view of iron bed is also seen here). A section of this plate is also seen in drawing marked X. B is a plan of heads showing the whole construction. The bearings are held down by a flat bar and two nuts. This plate is much thinner where it is fitted into the head than where it supports the bearings. These plates require careful fitting, being kept flush with the top of the wooden heads, and fixed with large screws. The mandrel is 15 in. long, 1⅛ in. thick at front bearing, ⅞ in. at back one, with collar as shown, and back centre to tighten up. The fly-wheel is 30 in. diameter, of cast iron, with a wooden rim fitted compactly and firmly round the iron; the grooves, four in number, are turned on the wooden rim, and being turned on its own axle, ensures perfect truth in running. The top pulley is about 10 in. diameter, smallest speed being 4 in. A brass dividing plate completes it. The main axle is 1¼ in. square, with two cranks. The bed of this lathe is 10 feet long, but the cast-iron part is only 6 feet, the remainder being carried out in wood, fitting well with the iron, as we seldom work so far back. The lathe is capable of very heavy work—such as wheel naves, or hubs, as they are called in England; these are from 8 in. to 12 in. diameter. We also turn all our wheels not exceeding 20 in. on it; it also carries a circular saw, 12 in. diameter, which is one of the most useful tools in a country shop. I have seen the hand or foot-power saw condemned in print. All that I can say is we would not lose ours on any account. The speed and accuracy with which 2 in. deal can be sawn, for instance, into such stuff, would rather astonish the eloquent advocate of the rip saw; it is not only the speed, but they are so accurately done that they can be dressed up with the plane in no time. I know what it is to dress up hand-saw work; as we say down here in Roxburghshire: 'it is nae better than it's caa'd.' Then for cutting tenons

it is first-rate; in order to dress a 12 in. saw lightly, it requires the band from a 24 in. speed to the 10 in. one. But I am afraid I am wandering, or maybe maundering away from my text. Any competent workman would have no difficulty in making such a machine; one man made it, and this in the year 1830, when there were no such tools as can be had now. The general idea was taken from a popular cyclopædia of that time, and, honestly speaking, it has not cost us over twenty shillings for repairs; and the parts which failed were of birchwood, these being the two cross feet and the top pulley. I shall be glad to answer any questions regarding this lathe, if anyone should try his hand."—[This is a capital latbe. It must have been a stunner sixty years ago. In these days, cast iron is so cheap and easily worked, I doubt whether it would be a saving to make such a latbe of wood now. If I am "the eloquent advocate of the rip saw," I should want to know, before modifying my opinion thereon, whether our Roxburghshire joiner can drive that 12 in. saw with his unassisted foot when ripping 2 in. deal for blind slats. He may, perbaps, at a speed ratio of only 10 to 24, which is very slow. Query: Wbat is tbe most advantageous speed for a circular saw driven by *one man?* As, however, PRACTICAL JOINER turns up naves of 8 in. to 12 in. diameter, I rather think he must be in the habit of calling upon one or two others to help bim tread; or, does he use the engine the cylinder of whieh he bored? A 6 in. or 8 in. saw is very hard to drive when cutting 2 in. wood at ordinary speed; do we make a mistake in running our saws so fast?—F. A. M.]

## II.—QUESTIONS ANSWERED BY EDITOR AND STAFF.

**Hive for Transportation.**—BAR FRAME, J. J., AND OTHERS.—BAR FRAME asks for a description of a hive which would be suitable for moving to the heather by rail or boat; and, as I have such a hive in my possession, a short account of it will probably be acceptable to others as well as to BAR FRAME. It is a twin hive, capable of accommodating a couple of strong stocks, but, if it is thought too heavy in this form, it might easily be made half the length, when it would do for a single hive, and be more easily carried about. Twin hives, however, possess tbe advantages of economising heat, and being almost as easily made as single ones while doing the work of two. To make this hive, I first construct a box of inch stuff, 17 in. by 31 in. internal measurements. It is 9 in. high, and the bottom is nailed on, plenty of good glue being applied to every joint. Before the bottom is nailed on, I cut a doorway ⅜ in. high and 8 in. long out of each end. I also strengthen



Hive for Transportation. End of Porch.

the bottom with three or four cleats nailed across. It is to be understood that the bottom is planed flush with the sides all round. I next prepare the inner sides, which are to support the ends of the frames, and give the hive double walls. These are two in number, 3¼ in. long, ⅝ in. thick, and 8¾ in. high. They are bevelled on top, leaving about ⅛ of an inch to support the frames, or a strip of tin might be tacked on for the same purpose, in which case the inner sides would be 8½ in. high, the tin bringing them to 8¾ in. These sides are next nailed in place, leaving a space between them of 14½ in.; nails should also be driven up through the bottom into tbese sides, to give additional strength to the structure. The ⅝ in. space between the inner and outer sides may now be filled with cork-dust, chaff, or some other non-conductor of heat, and a small strip of wood nailed on top to keep it down. So much for the body of the hive, which will require a well-fitting dummy to keep the stocks apart. The roof I make on the Cowan principle, sloping from 4½ in. to 9 in. in height; in the breadth of the hive, the top is covered with ½ in. boards, placed edge to edge, covered with calico and painted. If three crates of sections are used, a riser 8½ in. high and the size of the body-box will be required. Plintbs break the joints between body-box, or riser and roof. Tbe hive is now complete, except for the alighting board and porch, whieb I make in one. As it is rather more difficult to describe than the body part of the hive, I give an end view of it (see sketch). I first cut pieces, which I may call the ends, to about the dimensions given in the figure, but this can be varied much. I then nail the top and back in place, having previously rebated the place for the doors in the latter; the alighting board comes last, and projects back far enough to support tbe runners. The length is about a foot, and the entire porch is secured to the hive with a couple of screws. It can thus be removed when a journey is in contemplation, and replaced with the greatest rapidity. I have now fulfilled BAR FRAME'S requirements in describing a hive handy to carry about, if the eaves are not made too wide; strong, and with few parts; and able to keep out tbe cold and rain at the heather. If it is made balf the length, it would be still more handy, but heat would not be so much economised. I hope observatory hives will be treated of in due time.—APIS.

**Plant Case for Window.**—DEW.—To give full details for making a case sucb as you require would

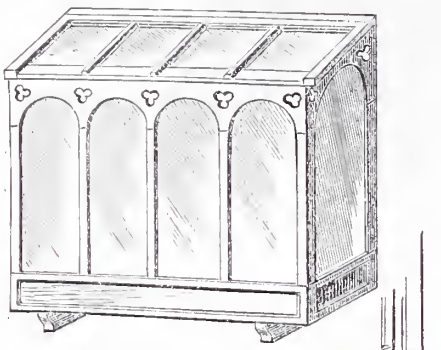


Fig. 1.

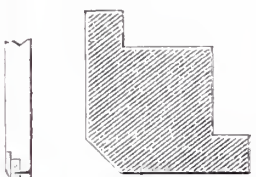

Fig. 3.

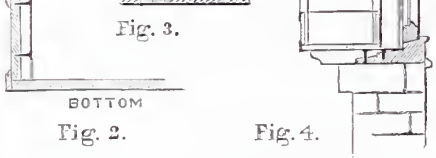

Fig. 2. Fig. 4.

Plant Case for Window. Fig. 1.—Side and End Elevation of Case. Fig. 2.—Section of Box, showing Fitting of Corner Post. Fig. 3.—Section of Corner Post. Fig. 4.—Section of Case and Window.

take up too much of the space available for "Shop" replies, but the following brief description may, with the aid of the sketches, furnish you with sufficient particulars for your purpose. Fig. 1 shows the appearance of the finished case, the lower part of which consists of a box made to fit the width of the window in which it is to be placed. This box is made of ⅞ in. wood, and is about 6 in. deep, the bottom being firmly screwed to the sides and ends. Slips of ½ in. wood, 1¼ in. wide, and having a small moulding or a plain chamfer worked on one edge, are then planted on to the outside of the box, so as to form panels on the front and ends, the piece on the top edge projecting ⅜ in. above the box to form a rabbet for the glass. The corner posts are then fitted in their place by cutting them away as shown in Fig. 2, and fixing them by means of screws. These posts are of the section shown at Fig. 3, and can be chamfered on the edges. Fig. 4 shows a section tbrough the case and window when in position, two brackets being fitted to the window-sill and firmly screwed down to it, upon which the case rests, being also secured at the top by means of two iron straps screwed on the woodwork of the case and window. The roof of the case should come just above the bottom of the top sash, so as to allow of its being pulled down if required. A piece of wood of the same tbickness as the roof is fitted close to the window-glass, and the roof is hinged to it, and can then be opened at the front. The semi-circular tops of the front and end openings are cut out of a piece of ½ in. wood, which is let in flush with the corner posts and bars, trefoils being cut out to lighten the appearance; the glass goes right up behind this wood, and covers the trefoil holes; or a very good effect can be obtained by cutting away the plain glass behind the holes and putting in blue or red glass; if your case is seen from the road, this is worth doing. Of course, a zinc lining is required to prevent the damp injuring the woodwork, and a pipe should go through one corner of the bottom to let away any surplus water. Use yellow deal if possible, and prime thoroughly with two coats of thin white lead before painting. I think these few hints will give you an idea how to proceed, but if you find any difficulty in tbe course of the work, write again.—G. LE B.

**Glazing Cuffs and Collars.**—LAUNDRY.—There are various ways of doing this. Putting a little gum arabic into the starcb is considered to give a nice glaze. Another way is with wax—into a pint and a half of boiling water in a saucepan put an ounce of wax; melt over the fire. When it has stood a few minutes to cool, stir into it half a pound of starch, previously mixed with a little cold water; the wbole to be boiled and stirred for half an hour. The wax starch thus prepared is to be used cold. We believe, however, tbat the glazing substance most used at the present day is borax. Some borax is dissolved in a saucer, the linen is starched in the usual way, an iron is passed over it, a clean rag is dipped in tbe borax and rubbed over the face of the article, and the ironing then finished.—S. W.

**Boot Soling and Welting.**—S. T. (*No Address*).—Round the sole a little wider than tbe last: any way, at the heel or outside joint. The breadth of the feather is decided according to tbe substance of the upper; but for medium work it must be about ¼ of an inch; and to make this feather, a strip of the leather must be taken away, and the lighter you want the sole to look when finished, the more of this you take away at A (Fig. 1). A line should be drawn round about ⅛ of an inch from the edge, and the awl put in here in holing, as B, and brought out at C. Tbis is all done on a board, not on the last, as an insole is fitted. For Question 1 you say a "turned pump." All pumps are turned, but all turned shoes are not pumps, and as you ask in Question 4 if you should start sewing at "the left-band corner of the heel," I conclude you mean what are called "sew-rounds"—that is, it is sewn all round while it is inside out, whereas the heel of a pump is made after the shoe is turned to its right side out. The sole should be tacked to the last with four tacks (the sole being grain side to the last), and then the upper lasted on with tacks, as you would for a welt: only use small tacks, and the tops must be lasted inside out. The sole should be fitted for this class of work to such a nicety (that is, have a very clean-cut edge), that after it is turned and second lasted it should need only to be coloured and ironed. The stitches for a gent's should have about five to the inch, and you should commence stitching at the corner of tbe heel, sew up one side of the waist, round the foreport, down the other side of the waist, and then round the heel. The feather for a broad welt can scarcely be too narrow—in fact, it must be sewn full, or its beauty is spoilt; and after the welt is sewn in, it should be beaten up, not between "two bammers," but with a welt-beater in the left hand and the hammer in the right. A welt-beater is generally made from

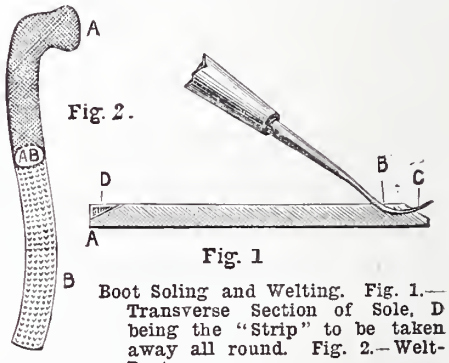

Fig. 2.

Fig. 1

Boot Soling and Welting. Fig. 1.—Transverse Section of Sole, D being the "Strip" to be taken away all round. Fig. 2.—Welt-Beater.

an old rasp, beaten out while hot, and turned over, as in Fig. 2, and A is put between the upper and welt, and B forms the handle.—W. G.

**Shading Marquetry.**—J. K. (*No Address*).—Such shading as you refer to may be done with hot sand, heaped up in the centre of the veneer you wish to shade, if it is large enough. All such work requires "dodging." It cannot be done mechanically. It may also be managed by heating a piece of iron till it is hot enough to brown the wood when held near it. Use either tbe end of the poker or a piece of wire, according to tbe size of the work. I cannot say how your old specimens are done without seeing them, and very likely I should not be able to tell even then, as no doubt old workers had their own methods of doing out-of-the-way jobs like this one, just as they do now. When an operation is a common one, one or more recognised methods are generally practised, because they have been found the best for obtaining a desired result; but in exceptional cases the worker must be guided by his experience. This will sufficiently guide you, whether you are merely asking from curiosity or because you wish to imitate the work. In this latter case you may be glad to know that the shading may be done with ordinary water-colour paint on the surface, after the veneer has been laid and cleaned up.—D. D.

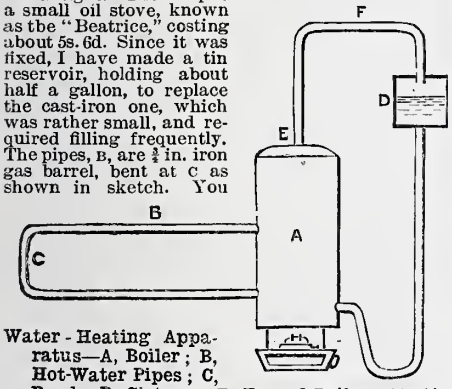
**Fretwork.**—F. G. (*London, N.*).—No elementary articles on this subject have appeared yet, but some are in course of preparation.—D. A.

**Hand Camera.**—E. T. (*Bruntcliffe*).—They vary a little in detail, but both are useful instruments. Abrahams, in Aldersgate Street, has a very simple and workable one—the movement of one lever changing the plate and fixing another ready for exposure.—D.

**Painting Inside of Aquarium.**—JACK OF ALL TRADES.—Try Aspinall's enamel; choose the colour you think will best suit the aquarium and put on three coats, allowing each sufficient time to dry, and do not put in the fish until you have had it filled with water for, say, a fortnight, changing the water every two days during that time. A friend of mine has recently treated an aquarium similar to yours in this manner; it has now been in use about six months and is perfectly watertight, while no apparent harm has been done to the fish.—G. LE B.

**Austin-Leclanché Battery.** — J. A. (*No Address*).—The ingredients and all other accessories required for making and fitting up the Austin-Leclanché Battery can be obtained from Whitney's, the Science Depôt, City Road, London; also of Caplatzi, 3, Chenies Street, Tottenham Court Road, W.C. Either of these will favour you with their price lists for inspection by enclosing postage. The price of Mr. Caplatzi's list is 2d.—H. E. A.

**Water-Heating Apparatus.**—A. H. H. (*Birmingham*).—You do not state the size of the building you propose to heat, but I imagine from your query that it is a small fernery or window conservatory. A friend of mine fitted one with hot-water pipes as shown in sketch, and he is perfectly satisfied with it. I will describe it as he made it, but you need not follow it in all details, as he had the saucepan and lamp by him, and you may have something else that will do as well. The boiler, A, consisted of a two-gallon tin saucepan with the handle removed and the lid soldered down. Any other utensil will do as well, providing you make it water-tight. The lamp is a small oil stove, known as the "Beatrice," costing about 5s. 6d. Since it was fixed, I have made a tin reservoir, holding about half a gallon, to replace the cast-iron one, which was rather small, and required filling frequently. The pipes, B, are ¾ in. iron gas barrel, bent at C as shown in sketch. You



**Water-Heating Apparatus—A, Boiler; B, Hot-Water Pipes; C, Bend; D, Cistern; E, Top of Boiler; F, Air-Pipe.**

can, if you choose, use two bends, or two elbows joined with a nipple to form the bend, but you will find it cheapest and best to have it bent. The boiler must be placed either below or on a level with the pipes, as shown in sketch. You can run the pipes to suit your convenience, providing you take the pipe from near the top of the boiler, and return it to the bottom, as shown. If you run the pipes above the level of the boiler, it will be best to take the pipe from the top of the boiler, E, and run the air-pipe, F, from the highest point in the flow-pipe. You ask for dimensions of tank, but in a low pressure apparatus no tank is required, except for convenience of filling, as there is scarcely any loss of water. My friend used a cake tin for the cistern, and ran ½ in. composition gas-pipe to supply the boiler. The air-pipe is ¾ in. composition, and this must be carried above the level of the cistern. It need not be carried over the cistern if not convenient. The hot-water pipes are tinned at the ends and soldered into the boiler, but if you do not mind a little extra expense, it will be best to solder unions into the boiler, and connect the pipes to them. If you do this you will have no difficulty in making your connections, and will be able to disconnect and re-connect boiler easily at any time. If you find any difficulty, I shall be glad to assist you if you write again.—T. W.

**Bicycle.**—CYCLOS.—Complete sets for making diamond frame safety, consisting of tubes, stampings, hubs, ribs, tires, chain, forks, brackets, saddle, pedals, spring, and every item to complete the machine, can be bought of the St. George's Cycle Company, Upper Street, Islington, London, for the sum of 90s. I cannot say what parts are finished, but should say the hubs and bottom bracket are. Of course, the rims, tires, chain, saddle, etc., are finished. If CYCLOS will write to above address, they will give him a catalogue and list wherein the prices of all rough and finished parts are given. If CYCLOS is not much of a mechanic, he should get as many of the parts machined for him as possible. After that he may have difficulties, but no special ones, providing he reads up a treatise on the subject.—A. S. P.

**Clock Cleaning and Repairing** — P. H. B. (*Highfield*).—You did not enclose the letter you wished forwarded to PRACTICAL HAND.

**Speculum Grinding for a Newtonian Telescope.**—W. B. (*Bruntcliffe*).—I presume that you are acquainted with the principle of the instrument; if you are not, look it up in any elementary handbook on optics. Here is a rough diagram showing the arrangement of the mirrors and lenses. You will see that the light which falls on the large mirror, A, is reflected in a cone, which, before it reaches a focus, is intercepted by the small mirror, and turned aside through the eye-tube, D, to the eye-lens, E. The large mirror, A, called the *speculum*, and the small mirror, B, called the *flat*, will have to be ground and polished. If the speculum is to be, say, 6 in. in diameter (which is a good size to begin with, though you may make one larger or smaller if you wish), then the *flat* will be an oval about 1½ in. in the major, and 1 in. in the minor diameter. For the present, in order that you may set at once to work, let the *flat* drop out of the question, we will confine our attention to the speculum. You will want no tools, properly so-called, at all. What has to be done is this. *Given a flat disc of plate-glass, free from flaw or defect, to dig out one surface of it to a certain parabolic curve.* And if we are to set about getting this parabolic curve in an intelligent manner, and with a prospect of success, we must first make it a sphere. So, for the moment, forget the necessity for the parabola, and state the problem more simply, thus:—*Given a flat disc of plate-glass, free from flaw or defect, to dig out in one surface of it an exact spherical concavity.* The concavity must be such that its section will be an arc of the circumference of a circle, the radius of which will be twice the focal length of the desired telescope. The focal length of a concave mirror is, roughly speaking, the distance from the centre of the reflecting surface to the point where the lines of the reflected rays intersect, or, in other words, to the apex of the cone of reflected light. Thus, with a speculum 6 in. in diameter, for which a good focal length would be 5 ft., the curve of a diametrical section of the mirror must be part of the circumference of a circle 10 ft. in radius or 20 ft. in diameter. You must really master this, because, until you have mastered it, you cannot intelligently proceed. A gauge by means of which you will be able to tell when enough glass has been ground away can be easily made as follows:—Procure a lathe 10 ft. 6 in. long. Through it, close to one end, stick a long bradawl for a pivot, by which one end of it can be fastened to the floor, while part

The dotted lines indicate the manner in which the Light from the Object is reflected from the Speculum to the Eye. Fig. 2.—A, Concave Gauge; B, Convex Gauge. In each case the curve is much exaggerated.**

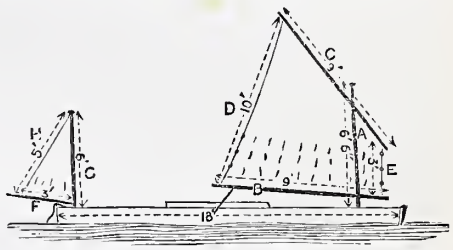
of a circle is described with the other end. In this other end, 10 ft. distant from the bradawl, fix a pointed steel tool. Underneath it, on the floor, place a 7 in. square of stout soft sheet zinc. Then, the bradawl being fixed firmly, the steel point may be made to mark the desired curve on the zinc, which must be cut with great care through the marked line, the curved edge being afterwards neatly worked together with a little wetted emery powder until they fit precisely. The straight-edge of the zinc can then be bent over (as in Fig. 2) and tapped down to keep the gauge rigid. The convex gauge, A, will fit the concave of the speculum exactly, the other gauge, B, we shall want to use otherwise by-and-by. Now for the glass. Get discs of plate glass 1 in., or better, 1¼ in. thick and 6 in. in diameter. You will be able to get them from any large plate-glass merchant, and they will cost a few shillings. The plate-glass people will cut them to a circle, but will leave the edges jagged. These edges must be smoothed down, either on a coarse grindstone, using plenty of water, or by mounting the two pieces of glass in a lathe and properly edging them. How to do this, I will tell you in another note.—E. A. F.

**Extracting Gold from Gilt Buttons.**—NO NAME.—From a jeweller's point of view, it is not worth the trouble and expense, there being so little gold put on. Even refiners do not particularly care to buy them at the low rate of 1s. per lb. I would go into the method of stripping by acid, but there are better methods I fancy in which a gilding battery is employed. Ask G. E. B. of WORK staff.—H. S. G.

**Pump Delivery, Pressure on Fittings, Contents of Tanks.**—TALBOT.—To find the quantity of water delivered in gallons per minute by a pump with a 4 in. barrel, multiply the length of stroke in feet by the number of *effective strokes* per minute, and by 0·5454. For a 5 in. barrel, replace the multiplier 0·5454 by 0·8522. This applies to any kind of pump. If the pump is double acting, all the strokes will be effective, but if single acting, only half of them. To find the pressure per square inch upon any fittings, measure the maximum height in feet of the water level above the fitting and multiply it by 0·434. The *size* of the supply tank does not affect the question. To find the quantity of water in an oblong or square cistern in gallons, multiply together the length, breadth, and depth, all in feet, and multiply the product by 6·25. To find the contents in gallons of a round tank, multiply the square of its diameter in feet by its depth in feet, and the product by 4·9.—F. C.

**Pantograph.**—J. B. (*Southwark*).—As a pantograph can be bought for sixpence, it is not worth your while to make one, for the materials would probably cost you more. You will find some remarks on the subject in "Shop," on page 669, No. 42, of WORK, which may be of assistance to you.—D. D.

**Canoe Sails.**—T. P. (*Islington*).—I submit rough sketch of sail plan that would suit canoe of dimensions given. The best article on canoe sails, etc., is in "Canoe and Boat Building," by Stephens, published by *Forest and Stream* Publishing Company of New York. A licence on the river Thames for a canoe from January 1st to December 31st is £2.—L. Y.



**Canoe Sails.**

**Mother-of-Pearl for Inlaying**—W. B. (*London, E.C.*).—The mother-of-pearl can be obtained from Mr. Henry Chatwin, 30 and 31, Darwin Street, Birmingham. He will also supply you with prepared shell of any thickness for saw-piercing, and will also cut it into shape if you like. The prices will be willingly given on application if details of thickness and quantity required are sent. The tools to work it that you will require are saws and files, all descriptions of which, including the polishing materials, can be obtained of Messrs. Cotton and Johnson, 14, Gerrard Street, Soho, London, W. Here is some idea of the cost: Saw-blades, from 3d. per dozen; piercing-saw frame, from 3s. upwards; file, about 6d., although you can get small ones down to 1½d. each. With these you should be able to get the shell into shape—that is, if you have it already slit to your desired thickness. If you wish to work from the shell direct, which I do not advise, you must go in for a hack-saw as well. With any or all of these tools use water or soapy water. To polish it, when you have done filing it, you must first get rid of the file marks with a piece of pumice-stone, ground flat, and water; then follow on with finely powdered pumice-stone and water, or oil, or better still with sulphuric acid and water. Vinegar will do if the acid is not to hand. The powdered pumice can be applied by means of a cloth lap (see a previous answer on polishing opals, etc.), or a leather buff, to be bought for a few pence at Gerrard Street; or even a piece of rag wrapped round a piece of wood. With this you must obtain quite a regular and smooth, but dull, surface. The next step is with similar tools, *not* the same, but to use powdered rotten-stone with any of the before-mentioned fluids. The final polish is best given with the palm of the hand, on which powdered rotten-stone is rubbed. Fine whiting may also be useful in place of rotten-stone. I think I will close this reply by mentioning a suitable pin or peg to aid you in piercing. You can get one at Gerrard Street. It is a piece of wood some 3 in. wide and 5 in. long, tapering from ¾ in. to ¼ in., and with a piece cut out like sketch. It is attached to a board or table by two screws, and projects some 4 in. from it. With this you should be able to work the thin shell without accident, for you can obtain support in any direction. One last word. Get your shell already polished if you can. The appliances and practice they have give a much better result than you will be able to get. I almost forgot to say that a grindstone will almost be necessary if you work the whole shell yourself. —H. S. G.

**Metals.**—AMATEUR.—You can get quantities of corrosive sublimate of Townson and Mercer,

Bishopsgate Street Within, or of J. Orme & Co., 65, Barbican, E.C. To make a saturated solution, dissolve ½ oz. of the corrosive sublimate in about 2 oz. of hot water. As it cools, the excess of salt will settle to the bottom, the remaining solution being saturated, and can be poured off to use, as mentioned in "Means, Modes, and Methods," page 714, Vol. II. Remember that corrosive sublimate is chloride of mercury, and very poisonous; the white of egg is the best antidote.—F. B. C.

III.—QUESTIONS SUBMITTED TO CORRESPONDENTS.

**Briar-Pipe Screws.**—C. W. B. (*Plymouth*) will be glad to be informed where to obtain bone screws for pipe-mounting, ⅜ in. up to ⅝ in. diameter.

**Papier-Mâché Doors.**—H. H. (*Cambridge*) writes:—"I have lately heard that doors of *papier-mâché* have begun to be made in Hamburg. Can any reader inform me whether or not this is the case, and where particulars relating to them can be obtained? It seems to me that such doors would be much less inflammable than doors made of wood, and could without much difficulty be made almost fireproof."

**Carved Wood Bellows.**—CARO writes:—"Can anyone tell me of a wholesale or retail address where I could get some bellows that I have carved nicely made up with brass nozzles and leather at a reasonable price; also where I can obtain similar bellows all ready for carving?"

**Ivory-Carving Tools.**—J. E. W. (*Camberwell*) writes:—"Will any reader please inform me where to get the above tools; also the lathe cutters used by carvers and stick-makers?"

**Turned Wood Cases.**—W. H. (*Stirling*) writes:—"I am in want of some cheap turned wood cases for packing a small phial in—size of case outside about 3½ in. long by 1¼ in. diameter. Can any reader oblige me with address of a maker?"

**Slate Pencil Preparation.**—R. M. (*Braintree*) writes:—"Seeing a recipe given in WORK, No. 102, for a blackboard preparation, I am led to ask for a preparation to be applied to wood or millboard, which could be written on with *slate pencil*. Something of the kind is sold, called carbon slate."

**Mice Cage.**—MART writes:—"Will anyone give me an ornamental design, with dimensions, for a white mice cage?"

**Lace Frame.**—MART writes:—"Will anyone give me a design and dimensions for a macrame lace frame?"

**Paper Machine.**—FOURDRINIER writes:—"Would any reader acquainted with the working of a Fourdrinier paper machine explain how the paper is transferred from the wire to the wet felt?"

**Castings.**—R. M. (*No Address*) writes:—"Will any reader give me some good information as to the best way of making my own castings? I want to make from 1 to 2 cwt. per day. Can I make them so as to be cheaper than 7*s.* per cwt., and what will be the probable cost of same?"

**Square Turning.**—F. W. (*No Address*) writes:—"Can any reader give me information of this kind of work? About what size wheels are used? How are the balusters, etc., fixed; and will the same wheels do for all kinds of work, or are the small articles, such as spindles, done in a different way? Do the turners use a gauge to get the mouldings to correspond on all the four sides?"

**Enlarging Drawings.**—J. W. (*Edinburgh*) writes:—"Would any reader kindly show the correct method of raising a drawing from half to full size; or the reverse, from full to half size? Say the scroll figured (page 760, Vol. II.), enclosed in a square (in rough numbers) 6 in. × 4 in. = 24 square in. If I take a half more each way, say, 9 in. × 6 in. = 54 square in., there is an excess of 6 square in. What is the rule?"

**Bright Steel and Cloth.**—STEEL writes:—"What is the best solution to stick bright steel and cloth together exposed to damp?"

**Battery.**—ELECTRIC writes:—"Would any reader oblige me with full particulars regarding the construction of a dry battery?"

IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**Electric Light.**—W. G. (*Erith*) writes, in reply to J. S. H. (*Dublin*) (see page 782, Vol. II.):—"If you have an ordinary bell-push, use a clip to keep the knob pressed down while you require the light. A cheap plug switch would be better, and may be obtained for sixpence; the necessary current may be supplied from two 3 pint agglomerate Leclanché batteries; these can be used exactly the same as in electric bell work, and will light up a 3-volt lamp for several years if only used for, say, five minutes per diem, and the current does not fall off as in the old form of Leclanchés. Of course, as many lamps as required can be used from the two cells, but only one at a time."

**Schooner Rigging.**—TEAK writes, in reply to T. C. (*Manchester*) (see page 782, Vol. II.):—"If T. C. wants a good book on Rigging, etc., let him write to the *Bazaar* Office, 170, Strand, London, W.C., for 'Model Yachts,' by J. Du V. Grosvenor, price 5*s.* 4*d.* by post."

**Cart Materials.**—W. P. (*Withington*) writes, in reply to W. S. (*Preston*) (see page 717, Vol. II.):—"I see that you are inquiring for addresses for procuring material and coach ironmongery for making a Battlesden cart. By writing to Mr. Wm. Cary, Red Bank, and Tomkinson & Co., Oxford Street, both of Manchester, you will be able to procure all that you require."

**Photography.**—C. M. V. (*Forest Gate, E.*) writes, in reply to C. E. H. (*Horwich*) (see page 734, Vol. II.):—"The method inquired for is termed 'Transparleum.' The company who introduced the process was the Continental Novelty Co., Leicester Square, London."

**Joiners' Bits.**—M. (*Bishop Auckland*) writes, in reply to A. A. W. (*Leicester*) (see page 734, Vol. II.):—"The bits used by joiners are shell-bits, centre-bits, American twist-bits, and expanding-bits. Shell-bits are semicircular, with the end turned up to form a cutting edge; they are slower in action, but not so liable to split the wood. Centre-bits have a centre point and two cutting edges, one cutting the side and the other the bottom of the hole. American twist-bits are formed like a screw, with two cutting edges, and a taper screw point; they are very quiet in action. Expanding-bits have a taper screw point, and a movable cutter for various sized holes."

**Cardboard Models.**—C. P. W. (*London, E.*) writes, in reply to J. F. (*Mullingar*) (see page 634, Vol. II.):—"So far as I can learn, there are no very exhaustive works on the subject. The only one I know of forms one of Weale's series published by Messrs. Virtue & Co., Amen Corner, Paternoster Row, E.C., and is entitled 'Practical Instructions in the Art of Modelling in Architecture,' by T. A. Richardson, price 1*s.* 6*d.* It is a very useful little treatise, but only professes to be elementary."

**Transparleum.**—DEAN FOREST writes, in reply to C. E. H. (*Horwich*) (see page 734, Vol. II.):—"In answer to your query, the name of the process of painting photos on glass which you could not recollect, is, I believe, 'Transparleum.'"

**Frosting.**—W. P. (*Withington*) writes, in reply to BETA (see page 734, Vol. II.):—"First clean the inside of the window, and polish it dry; then get some white lead, ground in boiled oil, and a little driers, and paint the window, twirling the brush round to imitate frosted glass. Do not paint too thickly, or you will obscure the light; leave for a few days to thoroughly harden; get the rule, and measure an inch next to the sash, and mark all round; get a straight staff and a blunt bodkin, and run it up on the paint by the side of the staff, thus marking the window all round; this, when well done, gives a nice finish. Stars and diamonds can be done in this way, drawing them first with a blacklead upon the paint; they should, however, be done with a geometrical preciseness, and I assure you the effect both from the inside as well as outside is very pretty. If left plain, it should, however, have a fine border, as already shown, an inch from the sash all round, to take away the plainness of the thing."

**Electric Light.**—H. E. (*London, N.W.*) writes, in reply to J. H. S. (*Dublin*) (see page 782, Vol. II.):—"From twelve to twenty large size Leclanché cells (according to resistance of lamp) will light a small incandescent lamp for from five to ten minutes at a time during a period of from twelve months to two years, according to use. An ordinary electric bell-push, or pressel, can be used, or a two-way switch, as most convenient. This is the least troublesome method."

**Hardened Putty.**—H. E. (*London, N.W.*) replies to J. G. (*Hull*) (see page 782, Vol. II.):—"If only a small quantity is wanted to be kept, put it into a vessel and cover with water. If a tub, pour a thin layer of linseed-oil over. If you wish to soften some hardened putty, knock it up with some linseed-oil with a mallet."

**Hand-Power Circular Saw.**—A. R. (*Scorrier*) writes, in reply to S. P. (*Penarth*) (see page 782, Vol. II.):—"If S. P. has plenty of money to dispense with, let him give it to the poor rather than lay it out in a machine that would be worse than useless to him for the work he wishes to do. If S. P. has no back numbers of WORK, I would advise him to get at least all the numbers of Vol. II., in which he will find both sketches and information how to drive small circular saw benches for cutting shallow stuff. But he must not expect to cut 5 in. deep, unless he has other than hand-power. To drive a circular saw by hand is not work for a man, even in shallow stuff."

**Lacquer for Brass.**—W. P. (*Withington*) writes, in reply to PATIENCE (see page 734, Vol. II.):—"Take 2 oz. of shellac, and dissolve in one pint of alcohol, coloured with turmeric; this turns the lacquer yellow. Clean the brass, and polish well off; then place it in a warm oven or before the fire, and apply this lacquer with a camel-hair brush. Keep the article in a warm place until the lacquer is quite dry, or it will be dull and lustreless."

V.—BRIEF ACKNOWLEDGMENTS.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—E. C. (*Redruth*); OLD PAINTINGS; J. C. B. (*Gt. Ayton*); C. C.; SELF-HELPER; MACHINERY MARKET; S. E. (*Chelmsford*); R. C. (*Exeter*); GIMEL; C. G. (*St. Albans*); A. M. (*Rochdale*); H. E. L. G. (*Liverpool*); A. B. (*Edenfield*); IRIS; W. C. # "WORK" EXHIBITION.

## DISTRIBUTION OF PRIZES.

THE STATIONERS' COMPANY having kindly placed

STATIONERS' HALL

at the disposal of Messrs. CASSELL & COMPANY for the Distribution of the Prizes gained at the recent "Work" Exhibition, Notice is now given that the

MEDALS, PRIZES, AND CERTIFICATES

will be given away on

TUESDAY, MARCH 24, at 8 p.m.,

At STATIONERS' HALL,

*STATIONERS' HALL COURT, E.C.*

All Exhibitors who can conveniently attend are invited to be present, and will be admitted on production of their Admission Ticket to the late Exhibition or Visiting Card bearing their registered number.

Each Exhibitor will be entitled to bring a friend.

WORK

*is published at La Belle Sauvage, Ludgate Hill, London, at 9 o'clock every Wednesday morning, and should be obtainable everywhere throughout the United Kingdom on Friday at the latest.*

3 STOPS

# THE WONDERFUL ORCHESTRAL ORGANETTE

(BY ROYAL LETTERS PATENT.) *Hundreds of Testimonials.*

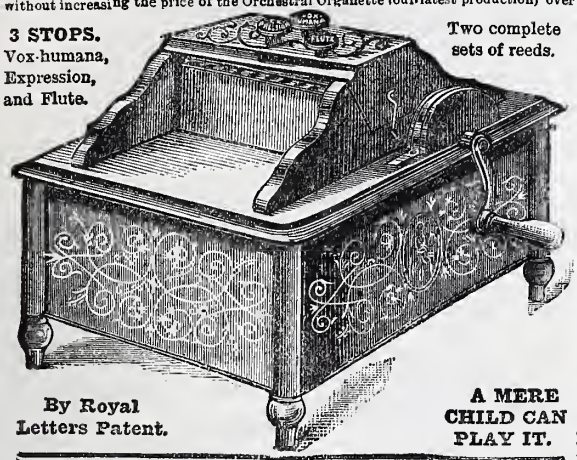
3 STOPS

## A FOUR GUINEA ORGANETTE FOR ONLY 35s.

WE are the sole Proprietors in the United Kingdom for this New and Wonderful Instrument. Having for many years manufactured and sold enormous quantities of Automatic Reed Organs, Organettes, &c., it has ever been our aim to produce at a low Price an Organette capable of a VARIETY OF TONES, the Organettes heretofore placed before the Public having but a limited compass, and but one range of tone. While we have given universal satisfaction, we still have had as our motto, "Excelsior," and now can exclaim, "Eureka!" because, without increasing the price of the Orchestral Organette (our latest production) over other instruments in the market, we have succeeded in producing the very ACME OF MUSICAL INVENTION, an instrument with as much variety of tone as an organ costing £25. The illustration gives you but a faint idea of general make and finish, but every Orchestral Organette is supplied with 28 FULL SIZED AMERICAN ORGAN REEDS, the same size and quality as those used in a cabinet organ. The reeds are placed in a novel manner (patented) over a double suction bellows, and are controlled by THREE STOPS, as follows, viz., Flute, Expression, and Vox Humana. The music is produced by perforated sheets, which pass around the Organette in endless bands, enabling a tune to be played over and over again without stopping, furnishing the GRANDEST ORCHESTRAL EFFECTS, either in sacred, secular, dance, or vocal music, affording a rich, sonorous, and powerful accompaniment to the voice, requiring absolutely no skill in the performer, and THE RANGE OF MUSIC AND TONE IS PRACTICALLY UNLIMITED. By the manipulation of the stops, a tone as soft and sweet as a zephyr, or a loud, long and swelling melody may be produced; trills and high falsetto, as well as reverberating bass, and all manner of pleasing combinations at the will of the performer.

**3 STOPS.** Vox-humana, Expression, and Flute.

Two complete sets of reeds.



**By Royal Letters Patent.**

**A MERE CHILD CAN PLAY IT.**

We wish to introduce one of these Orchestral Organettes in every town and village in the United Kingdom. We caution you against the many worthless automatic instruments being sold under various names. We are the SOLE PROPRIETORS OF THE ORCHESTRAL ORGANETTE (*ne plus ultra*) and you must order direct from us or through our authorised agents. Remember, the Orchestral Organette is NOT A TOY, but a LARGE and POWERFUL INSTRUMENT, built exactly on the principle of CHURCH ORGANS; they are made in the most substantial manner, highly polished, and decorated in gold. The reeds are the product of machinery costing thousands of pounds, and are so powerful they produce sufficient volume of music for the drawing-room, chapel, lodge, or ball-room. There is nothing about them to get out of order. They positively improve with age, producing richer and sweeter tones after having been used a few years. For HOME ENTERTAINMENTS THEY ARE UNSURPASSED. Bear in mind that each instrument has FOURTEEN MORE REEDS than any other Organette in the world, and they are ORGAN REEDS, and the special feature is THREE STOPS, a characteristic of no instrument except a costly organ. Our regular price for the Orchestral Organette is £4 4s. Having just put it before the public, we will sell a limited number to the readers of this Paper at £1 15s., provided the above Coupon is cut out and sent with order not later than the date given in it, and we furthermore agree to REFUND THE MONEY and PAY CARRIAGE to anyone not entirely satisfied after receiving it. By the aid of the Stops—viz., Expression, Flute, and Vox Humana, there is not a piece of music which cannot be played with all the varying effects of an orchestra; a false note is an impossibility, and the most difficult operatic air is played with as much ease as the most simple hymn. In many homes will be found a Grand Piano or Organ, with not an inmate of the household, even the most expert player, who can interest company on either so well as a child of three years old can on the ORCHESTRAL ORGANETTE. Remember any tune can be played with artistic effect by anyone, young or old. You can play DANCE, SACRED, OR SENTIMENTAL MUSIC with as much effect as that produced by a FIRST-CLASS FOUR-PIECE ORCHESTRA. Remember our regular price is £4 4s., but as we have found a well pleased customer our best advertising medium, have decided to sell a limited number, as an introduction to the readers of this paper at £1 15s., provided the order is received not later than the date printed in the Coupon immediately beneath the illustration of the Organette. We will give a selection of MUSIC FREE with each instrument. Send Money and Coupon by Registered Letter, Crossed Cheque, or Money Order to J. DRAPER, Manager, British Organette Co., Blackburn. For 2s. extra the Organette will be sent to any part of the United Kingdom, *Carriage paid.* List of tunes and Testimonials sent anywhere free. Visitors can inspect the Factory daily from 9 a.m. to 7 p.m. Saturdays close at noon.

*N.B.—Above time is extended for Foreign Customers.*

COUPON 678a.

REGULAR PRICE, £4 4s.
REDUCED PRICE, £1 15s.
GOOD UNTIL MAY 1ST, 1891.

*Signed*, J. DRAPER.

Any reader of this paper who forwards this Coupon before the date named herewith can receive ONE Orchestral Organette at reduced price of £1 15s.

**£500 CHALLENGE.**—We will give £500 to anyone who can prove that we ever solicited a testimonial, or that any in our Catalogue are not genuine. During Oct., Nov., and Dec., 1890, we received 500 testimonials for our Orchestrals. Surely this speaks for itself.

**FLUID WATER RESISTING GLUE** (*Patent*) PATENT TINS.

*Invaluable for all Out and Indoor Repairs.*

**FLUID WATER RESISTING GLUE** (*Patent*) PATENT TINS.

No Brush—No Boiling—Will securely join Wood, Glass, China, Metale, &c.

*By Post, 8d. and 1s. 3d. per tin. Through Ironmongers, Chemists, Chandlers, &c., 6d. and 1s. per tin.*

**Manufactured only by** THE WATERPROOF GLUE CO., 62, Dale St., LIVERPOOL.

**Cassell's Classified Catalogue** will be sent on request post free to any address. *Cassell & Company, Limited, Ludgate Hill, London.*

# A WONDERFUL MEDICINE.

# BEECHAM'S PILLS

Are universally admitted to be worth a Guinea a Box for Bilious and Nervous Disorders, such as Wind and Pain in the Stomach, Sick Headache, Giddiness, Fulness and Swelling after Meals, Dizziness and Drowsiness, Cold Chills, Flushings of Heat, Loss of Appetite, Shortness of Breath, Costiveness, Scurvy and Blotches on the Skin, Disturbed Sleep, and all Nervous and Trembling Sensations, &c. &c. The first dose will give relief in twenty minutes. This is no fiction, for they have done it in countless cases. Every sufferer is earnestly invited to try one Box of these Pills, and they will be acknowledged to be

**Worth a Guinea a Box.**

FOR FEMALES THESE PILLS ARE

"A priceless boon, a treasure more than wealth; the banisher of pain, the key to health."

These are FACTS testified continually by members of all classes of society, and one of the best guarantees to the nervous and debilitated is,

***BEECHAM'S PILLS have the Largest Sale of any Patent Medicine in the World.***

Prepared only by the Proprietor, T. BEECHAM, St. Helen's, Lancashire, in Boxes 9½d., 1s. 1½d., and 2s. 9d. each. Sold by all Druggists and Patent Medicine Dealers everywhere. *N.B.—Full Directions are given with each Box.*

# FRETWORK FOR AMATEURS OF BOTH SEXES AND ALL AGES.

Eclipse Design, No. 102.

Wall Bracket. Price 5d.

THE MOST PROFITABLE AND FASCINATING OF ALL HOME PASTIMES. EASILY LEARNT.

J. H. SKINNER & Co. having *Dissolved Partnership*, are offering their *Enormous Stock*, including 250,000 FRETWORK PATTERNS and 100,000 ft. of Solid and Three-Ply FRETWOOD, Veneers, &c.; 1,000 Gross of FRETSAWS, besides an immense quantity of TOOLS, OUTFITS, &c., as a special inducement to their customers to order at once.

**4,500 1s. Books of Fretwork Patterns**, each containing Twelve Large Sheets, beautifully lithographed, none of which would be sold retail at less than 2d., and many at 3d. and 4d. each; also

**1,200 2s. 6d. Books of Fretwork Patterns**, containing Twenty Sheets, 19 in. × 12 in., of new designs, many of which would retail at 6d. each. These Books,

**£375 in Value, will be GIVEN AWAY.**

Amateur customers ordering 5s. worth of designs from Catalogue will be presented with one of the above 1s. Books. Those ordering 10s. worth will receive a 2s. 6d. Book.

**An Allowance of 10 per Cent.** *in goods* will be made on all mixed orders for Wood, small Tools, Saw Blades, and Designs, amounting to 10s., and **15 per Cent.** on orders amounting to 20s. and upwards. NOTE.—*This reduction does not apply to Treadle Machines.*

N.B.—A SPLENDID OPPORTUNITY FOR BEGINNERS.

**Complete Fretwork Outfit**, comprising 12-inch Steel Frame, Forty-eight Saws, Awl, File, Four Designs (with sufficient Planed Wood and 1s. Handbook on Fretwork). **An Archimedian Drill**, with brass handle and Three Bits, will be **SENT GRATIS** with each Set. Post free for 3s. 6d. Outfits on Card, 1s. 6d. and 2s. 9d., post free. 6 ft. 2nd quality assorted planed Fretwood, 1s. 9d.; post free, 2s. 6d. 12 ft. ditto, ditto. 3s.; post free, 4s. 3d.

**SKATES!!!**—EVERY PAIR WARRANTED.—Sizes, 7½ in. to 12 in. No. 1, Unpolished Beech, 10d. per pair. No. 2, Polished Beech, 1s. 6d. per pair. No. 5, "Acme" pattern, all steel, 3s. per pair. No. 7A, "Caledonia" pattern, self-adjusting, one screw fastening the whole skate, the best principle, 6s. per pair. No. 8, Metal frame, with strap complete, 1s. 9d. per pair; postage, 5d. per pair. These are not rubbish; we warrant every pair.

**NEW CATALOGUES** of Machines, Designs, Wood, Tools, etc., with 600 Illustrations and full instructions for Fret-cutting, Polishing, and Varnishing, price 4d., post free. A Specimen 6d. Fretwork Design **SENT GRATIS** with each Catalogue; also a List of Designs, Outfits, Tool Chests, etc., at Greatly Reduced Prices to clear.

N.B.—All orders *must* be accompanied by remittance. APPLY—

**J. H. SKINNER & CO.,** Manufacturers of Fretwork Materials, W Department, *EAST DEREHAM, NORFOLK.*

*Kindly mention this paper when ordering.*

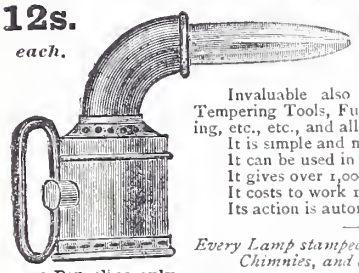
# CROWDEN & GARROD

ARE SOLE PROPRIETORS OF THE

"PAQUELIN" PATENT PAINT-REMOVING LAMP.

**12s.** *each.*

DIRECTIONS SENT WITH EACH LAMP.



Use Benzoline only.

*Thousands have been sold and give the greatest satisfaction.*

Invaluable also for Soldering, Brazing, Joint-making, Tempering Tools, Fusing Metals, Lead Burning, Pipe Thawing, etc., etc., and all Plumbers' Work.

It is simple and most effectual.
It can be used in almost any position.
It gives over 1,000 degrees of heat.
It costs to work 1d. for four hours.
Its action is automatic. No pumping is required.

*Every Lamp stamped* **V.V.** *is fitted with White Hard Metal Chimnies, and contains all the* 1890 *improvements.*

PAINTING BRUSH MANUFACTURERS AND GENERAL MERCHANTS,

*62, SOUTHWARK STREET, LONDON, S.E.*

# Bovril.

**Invaluable as a Strengthening and Invigorating Beverage.**

Indispensable for Enriching Gravies, preparing Soups, Entrées, &c.

Pure, Palatable, instantly prepared. **Bovril.**

WILL KEEP ANY LENGTH OF TIME.

*SOLD EVERYWHERE.*

*A COMPLETE NOVEL, entitled*

## "AS IT WAS WRITTEN,"

"which," says *The Graphic*, "is equally imaginative, at least equally strong, and beyond all question superior in literary and constructive skill to 'Called Back,'" is

*GIVEN AWAY* with *No. 390 (Now Ready,* price **One Penny)** of

# Cassell's Saturday Journal,

in which a New Serial Story is commenced, entitled **"Olga's Crime,"** by FRANK BARRETT, Author of "Fettered for Life," etc. etc.

No. 390 *forms a* Double Number, consisting of 48 Pages, *and contains amongst other attractive features:—*

1. **Political Leaders and their Followers.** With Facsimile Letters from the EARL OF DERBY, the MARQUESS OF HARTINGTON, MR. GLADSTONE, and MR. AKERS DOUGLAS, M.P.
2. **Major Clay's Victim.** Complete Sensational Story by JOHN K. LEYS, Author of "The Lindsays," etc.
3. **Men who have Hoaxed Themselves.**
4. **An Interview with Dr. Samuel Smiles.** Illustrated.
5. **Sergeant Von's Chase.** Serial Story. From the Diary of Inspector BYRNES, Chief of the New York Detective Force.
6. **My Experiences with Graphologists.**
7. **A Visit to the Returned Parcel Office.**
8. **Female Rogues of To-Day.**
9. **Blind Man's Buff on Horseback.** Complete Story of Adventure. By DAVID KER.
10. **Revelations about Songs and Singers.**

**N.B.—Part 91** of **Cassell's Saturday Journal**, published **April 27**, price **6d.**, will contain **144 Pages**, including the Celebrated Story, **"As it was Written."**

CASSELL & COMPANY, LIMITED, *Ludgate Hill, London.*

Prevents and relieves **INDIGESTION, FLATULENCE, DYSPEPSIA, HEADACHE**, and all other Stomachic Irregularities. **PURIFIES** the **BODY**, imparting **NEW LIFE** and **VIGOUR**. Possesses marvellous recuperative properties. Is invaluable in relieving and stimulating the overworked brain and resuscitating exhausted vitality.

# SALT REGAL.

LIEUT.-COL. HUGH BAMBER, 40, HANLEY SQUARE, MARGATE, says:—"I have now used the **SALT REGAL** for two years. I have much pleasure in stating that I have found it the most agreeable in taste of all Salines, and a certain cure for bilious headache and furred tongue, from whatever cause arising."

2s. 9d., of all Chemists and Stores, or by Post from the **MANAGER, SALT REGAL WORKS, LIVERPOOL.**

**BRIGHTENS** and **CLEARS** the **COMPLEXION**, and is highly recommended by the **MEDICAL** Profession. Corrects all **ERRORS OF DIET**, eating or drinking. Is a most pleasant effervescing morning drink, **STIMULATING** the **APPETITE**, and giving tone to the entire system.

## STENCILLED DECORATIONS FOR A DRAWING-ROOM.

BY A LONDON DECORATOR.

THE ornamental designs accompanying this paper are intended for use in conjunction with the stencilled ceiling which appeared in Vol. II., page 133 (No. 61) of WORK. As a serviceable introduction to this article, I must therefore strongly advise readers who may take a practical interest in the present effort to carefully peruse the above. In common with the ceiling design, an attempt has herein been made to meet the different circumstances of the worker's ability and requirements.

Contemporaneously with the ordinary householder's "spring cleaning" comes the house-painter's and decorator's "spring season" of work. The present is therefore a very *à propos* time to invite attention upon home embellishment; and whilst I think the work now suggested to be within the capabilities of many amateur decorators, an effort has also been made to proffer useful hints for the professional painter and decorator—both with regard to material used and resultant effects.

In the article upon ceiling design of the "Adams" type, besides explaining the useful adaptability of such disconnective ornament for our purpose, it was advised that the work

be carried out in two or three simple tints. For use with many wall-papers, a blue tint of ceiling design upon a soft cream ground was given as being very effective; whilst further mention was made of executing it in other monotone tints of terra-cotta, etc., where the cream and blue would be unsuitable. "Adams" ornament—so named after the celebrated architects, the Brothers Adams, who introduced it—is at the present time in much use for high-class and costly drawing-room ceilings. In such cases it is usually made in fibrous plaster, and then affixed to the surface. In trying, therefore, to reproduce in flat tints the effect of a delicately modelled ornament in low relief, the relative amount of contrast between the ground and design is a very important factor in the success of the work. On the one hand, we must avoid that extreme which gives a sensation of Pompeian harshness and fussiness—such as we get in simple black and white; whilst, on the other hand, the design must be sufficiently plain for the eye to follow it under all fair conditions of lighting, without the least strain to the sight. "Taste"—that highly convenient jargon in matters of individual selection—can very often be taken as an attribute of common sense; and in the above respect it will be found that decoration which is based upon the latter will generally be conceded to express the best, or "correct taste."

Turning now to the practical aspect of this decorative treatment, we will consider Fig. 1 of the illustration. Judging by the paper-stainers' new designs for the present year, we may safely state that dados for the decoration of drawing-rooms are rapidly "going out" of demand, and that deep frieze decorations are in stronger call. For the drawing-room—"with-drawing" room—pure and simple, where the apartment is but seldom used, and then only for special social purposes, a dado is certainly a superfluous feature. The notion that dados were merely the outcome of a wall chair rail, and not purely a decorative feature, is still as prevalent as it is erroneous; and the intimation that their source can be explored in the ruins of ancient Pompeii comes equally as a matter of surprise to many. Judging again, however, from the common-sense basis, we decide upon these grounds: whether the amount of elaborate work would be sufficiently displayed according to the arrangement of our furniture; whether, if we simply carry the plain treatment down to the skirting, we shall probably have any objectionable dents and finger-marks to catch and worry the eye; whether the height of wall is adapted for a dado; and so forth. This vexed question being perhaps settled in the general affirmative, I give a few instructions for its execution. With regard to these designs, it may be thought that a worker who can draw them large enough to use would probably be able to produce his own design, and *vice versâ*. Such does not, by any means, always apply. The main feature of "Adams" work is a repetition of simple forms in graceful lines; therefore, given this feature, the exact proportion of a reproduction of my illustrations is not a necessity. All wall stencil-work, if it be above the level of ornamental doggrel, must be drawn with direct regard to the size and disposition of the room, hence it follows that, with the exception of ceiling ornaments and simple borders, sets of ready-cut stencils can seldom be applied to an apartment without much re-arrangement and often mutilation of the designs. The dado given is drawn to 1 in. scale, having alternating panels 18 in. and 9 in. wide. The height above skirting to top of border is shown as 36 in.

In applying panelled dado-stencils to a room, we must look chiefly to the dado breaks, such as door frame and mantelpiece make. At these positions the panels must appear intact, and not simply starting at one angle, and finding ourselves with half a panel to put in against the door, where every eye will catch sight of it. The best plan is to measure our wall lengths, and see what size "repeat" will then come in with least trouble. The half of each panel design must be first sketched in on paper with charcoal, and then carefully drawn with all detail—remembering that we are preparing *stencilled* ornaments. In all intersections and connective parts not less than ¼ in. of space must be interposed as natural "ties"; when stencilled, these will but nicely separate the parts, without any appearance of ugly breaks. If we make the tie spaces much less the stencil will not stand the wear.

Both the dado border—a "repeat" 6 in. by 9 in.—and the bottom simple "twist" pattern must be put in after the dado. If we wish to decrease the height of the latter, the base ornament can be substituted by a couple of lines. The "fuchsia" upright margins to panels will best be put in separately, whilst the narrow panel can be easily adapted in width, as necessity may arise, by "humouring" the plain surrounding margin. All main dividing lines should be struck out with chalk line, etc., and the lines put in, lastly, with lining fitch and straight-edge. Two "repeats" of the stencil border will be sufficient to cut, and most convenient for one person to use.

The deep frieze combination of Fig. 2 can either be used as drawn or in parts. If it is wished to have a wooden frieze-picture rail, the same should be placed beneath the bottom straight line of design. If desired, the festoons can be then stencilled immediately beneath the rail, suspending the ornamental lines upon small "nail" ornaments. The main design of frieze has to be repeated on the right hand until the "vase" returns, each medallion being therefore 36 in. apart. If the cameo heads are used, the wall length of frieze must be carefully spaced out, and the medallions properly centred. Instead of the heads, simple circular pateras may be used for these positions, or relief plaques of "Lincrusta" or "Anaglyta" fixed therein. One repeat of the stencil, as shown, will be quite sufficient if we carefully set the wall-space out, stencil in all our left-hand halves, reverse and clean the stencil-pattern, and then complete the alternative sections.

Fig. 3 is a border design, to be drawn 9 in. in height, of a simple but effective design. This may be used as a border above a dado of plain colour, due allowance being made for the extra width. To produce the stencils, we must first draw the half of pattern, as illustration, on paper twice the length; then double the paper, pin it to a table, and mark over the outline with a wooden point and fair pressure. When opened, the impression of the second half will be discernible, and can then be transferred to the stencil-paper. The latter is best attained by rubbing the under side of drawing-paper over with a little dry colour before we outline the impression, and then pinning this inner side down on the cartridge-paper for a transfer of red outline by pressure as before. Fig. 4 is another border of decided horizontal lines, and is suggested for use, nine inches wide, above the wooden skirting in cases where the dado is not used.

The remaining items of our illustration in Fig. 5 refer directly to the door. The panels are proportionately those of the common four-panel door, and are placed in such a position to enable the effect of an "over-door" ornament to be fully appreciated. Where the deep frieze is used, the height of wall must be considerable to permit also of over-door ornament, and not less than, say, a foot of clear filling space should show between the nearest portions of each.

Now, a few notes respecting colours and material. In No. 53, Vol. II. of Work, an interesting illustrated paper appeared, disclosing the claims and merits of a new *tempera* paint, Church's "House Decorator"—or wall decorator, rather. The writer having, like many others, in a varied professional career, paid the purchase-money of some practical experience in connection with "patent distempers" and silicate paints, the contents of the above notice were individually taken with due caution—*cum grano salis*.* During the last few months it has been my privilege to make a pleasing working acquaintance with this new commercial product, now rapidly becoming known as "Alabastine," which is made and supplied by The Church Manufacturing Company, 127, Pomeroy Street, Hatcham, London, S.E.

To the new "Alabastine" tint circular we may now profitably give a little attention in the execution of this decorative work. A very chaste and decorative colour scheme may be carried out in this material upon the ornamental lines of my paper. For the ceiling ground, No. 7 tint may be used. Upon this admirable cream ground let the ceiling design be stencilled with No. 23, or flat paint made to that tint. The cornice may be treated in the same creams and blue. The wall may be coated right down to skirting with either Nos. 16 or 23, which will give an excellent "background" tint for drawing-room wall ornaments, the latter tint being lightened up, if necessary, for a badly-lighted apartment. The stencil dado and frieze must be executed in flat paint-stain (see article in No. 61), made with Prussian blue and raw umber to a sufficiently deep shade of soft blue, toned rather to dulness than brightness in colour. If a darker plain dado be wished, then a thin coat of flat paint of the desired colour, painted over the "Alabastine," would be the best job, and the dado border stencilled with the same colour, a darker line still intervening. For a warm treatment to a room of cold aspect, the Alabastine circular shows equally soft and pleasing tints. The frieze medallions, if painted, should be done in cream monochrome against blue background, the latter outlined with a fine line of gilding or darker blue. Where the ceiling and frieze designs may both be used, the circular panels of the former should be substituted by suggestions of the four "seasons," since the cameo heads of musical celebrities, poets, etc., must be

* Yes, our "London Decorator" objected very much to "Alabastine" when it was first noticed in Work, and I rather think he mentally placed me among the majority of the people of the United Kingdom, according to Carlyle's classification, for daring to predict a future—and a good future, too—for this new decorative material. It has taken only a twelvemonth to show that I was justified in advocating the claims of "Alabastine" to public favour. For the benefit of the readers of Work I may be permitted to say that the "Church Manufacturing Company," whose address will be found above, will readily send to any applicant their prospectus, with specimens of the various tints in which the material is supplied, including the newest additions to which allusion is made in this paper.—Ed.

the main feature of *one* portion only. The best treatment of woodwork would be enamelled-cream skirting, frame and stiles; panels in light-blue tint, flatted and lightly stippled, with ornament stencilled thereon in deep blue, and outlined with either fine gilded line or a deeper shade of blue. In the panel treatment of illustration the margin to panel would be painted a few shades darker than the remainder, and the marginal lines and corner *rose*, with also a bead on panel-mouldings, should be gilded. If something beyond the ordinary is desired for the panels, the worker may obtain a pair of the figure cameo panels made in "Lincrusta," and combine his handicraft therewith by using Alabastine in relief. To this end, cover the panels carefully with a stout white lining paper; paint these, when dry, with one coat of thin oil paint. Upon this mark the position of the panel, then coat in the panel ground with Alabastine, stippled as the flatting. Paint and finish the Lincrusta centre panel, and then work the other ornament on the lines of Gesso work, and according to the directions given with the new circular and the valuable product itself.

## ARTISTIC LITHOGRAPHY.

BY A. J. ABRAHAM.

### Printing Surfaces.

Derivation of Term—What Lithography is—Lithographic Limestone—Colour of Stone—Varieties of Limestone—Graining and Polishing—Testing Grain—Selection of Stones—Re-graining, etc.—Other Printing Surfaces—Zinc—Transfer Paper.

*Derivation of Term.*—The word lithography is derived from the two Greek words, "lith'os," a stone, and "graph'o," I write. Chromo-lithography is a further extension of the word from "chro'-me," colour.

*What Lithography is.*—Lithography is the art of drawing on a stone or other substance that is capable of retaining both grease and water, with a fatty or greasy matter, with the pen, brush, etc., in such a manner that when the stone, after being subjected to a treatment of acid, is damped with water and passed over by an inking roller, the drawing has protected the stone from the action of the acid, and has thus preserved its natural properties, which is the quality of receiving printing ink, whereas all the rest of the stone rejects the ink through the interposition of the water, which is antagonistic to grease; so, when an absorbent paper is pressed on the stone, copies can be obtained.

*Lithographic Limestone.* — There are several kinds of substances that can be used for this purpose, such as zinc, wood, etc., but up to the present time nothing has been found possessing the qualities required in greater perfection than limestone. This is found in quarries in several countries; but the best, both in quality and quantity, comes from Solenhofen, in Bavaria.

*Colour of Stone.*—These few hints being more for the use of the artist who draws on the stone, it will not be necessary to enter into the details of its chemical qualities, which really are of more use to the printer than the lithographer; but what it *is* necessary that he should know is that the stone is of different shades of colour, varying from a pale yellowish-white to a dark blue or greenish-grey. Those lighter in tone, being softer in composition, are only suitable for drawing with the pen or brush, but the darker ones being harder in substance, are more suitable for chalk, engraving, and the better class of work.

*Varieties of Limestone.*—Limestone is found varying from a line to several inches in thickness, when it can be easily cut from the surrounding earth. This is generally done in sizes suitable for commercial purposes at the quarries. As a rule, the printer will supply the artist with stones, the charge being by weight, so much per lb. according to the size of the stone, larger ones commanding a bigger price than smaller ones, stones darker in colour more than the lighter-toned ones; and those with a surface on both sides suitable for printing from are very expensive, on account of the difficulty in obtaining a stone that is of an even composition all the way through. These are termed double-faced stones.

*Graining and Polishing.*—When a stone is required for pen or brush work, it is ground level and then polished with pumice or snake-stone, and when required for chalk work, an artificial grain is given to it with ground glass or fine sand passed through sieves having holes of various sizes, according to the texture of the grain required; but as grinding the stone belongs to the printing department, all that the student need tell the printer is the size of the drawing for which the stone is required, and whether it be for ink or chalk work. It is also necessary to know whether a grain with a fine or coarse texture is required, according to the nature of the work, writings and small drawings requiring a finer grain than a larger, bolder style of work; but as the size of the sieves varies so much, and no two men grind the sand in quite the same manner, it would be impossible to state a regular size for any particular class of work; this the student can only obtain by practice and experience. A good plan would be, on trying several grains, and finding one suitable for the work in hand, to ask the printer the number used in graining that special stone, and if for any future work a coarser texture is required, subtract from it, and if for a finer grain add accordingly. This should in every case be done when the artist works with a different printer or grinder to whom he has been accustomed.

*Testing Grain.*—Before beginning his subject the student should test the grain, by making one or two marks with the chalk in different parts of the stone, when, if not found suitable, it can be easily re-grained. If made lightly, these patches do not affect the work, as they can be darkened if a deeper tint is wanted in that place, or taken away altogether if not required.

*Selection of Stones.*—In choosing stones for chalk work, see that the surface is free from veins (in appearance like a pencil-line drawn irregularly across the stone) and chalky spots (in appearance patchy or speckled in colour), as either veins or spots are apt to show when printed; but for pen work it is not of so much consequence, as the stone, being polished, does not exaggerate any imperfections such as veins, which is the case when an artificial grain is given to it.

*Re-graining, etc.* — The stone must be properly grained or polished before starting any drawing, or else old work which has been on the stone sometime may show through any new work that the artist may do. Although this does not come under the artist's supervision, still it is advisable that he should know what the result would be were the stone not properly prepared. It is sometimes necessary to reduce the thickness of the stone $\frac{1}{8}$ of an inch in cases where work has been standing for any length of time, as the ink adheres so strongly to it that it is impossible to remove it; and, of course, the longer it remains on the deeper it sinks, and unfortunately not being perceptible to the eye, it does not show, or, to use a trade expression, "work up," until it is in the printing machine. It is always better to have the stone rather larger than the paper required, in order that in printing the paper does not overlap the stone, else its edge is likely to leave a mark on the paper from the pressure of the machine.

The above subject has been perhaps enlarged rather more extensively than necessary, but as stone plays such a very important part in lithography, it cannot be impressed too strongly upon the student how particular he should be in selecting his stones, and seeing that they are properly prepared by the printer.

*Other Printing Surfaces.*—It is only necessary to touch lightly upon other printing surfaces, as the student having once mastered the art of drawing on stone, will find no difficulty in working upon foreign substances.

*Zinc.* — In reference to other materials suitable for printing purposes, zinc gains the advantage over stone in being lighter in weight, and therefore more easily moved and lifted about. It is not so expensive, and can be printed at the same time with letterpress, which is impossible with stone on account of its size. Being of a dark slate colour, however, it is very trying to the eyes, and unless the artist is sure of his work and able to judge of the different effects whilst it is in progress, he is likely to forget that the colour of the material has to correspond with white paper, and that a tint will only look half the strength on paper to what it does on the zinc, the grey shade of the surface giving an extra tone to the work, thereby softening the whole subject, which will look much harder and cruder on paper. This refers in a certain degree to stone, but not quite to the same extent, it being so much lighter in colour. The general tone of the work is not so much affected. Zinc cannot be used for lithographic purposes to quite the same extent as stone, as it does not possess those natural properties peculiar to limestone, which have been mentioned.

*Transfer Paper.*—This is a paper specially prepared with a grained surface for chalk work, and a smooth one for working with the pen, or brush, but when it is used the drawing has always to be transferred to stone before any printed impressions can be obtained. It is preferable to stone for some purposes, insomuch that whilst all drawings on the latter *must* be drawn the reverse way to the original sketch, any drawings on the above paper can be copied the same way, as they must be transferred to stone for printing purposes. This method is generally adapted for writings, legal circulars, billheads, plans, maps, architectural drawings, etc., but all artistic lithography, such as chromos, etc., should be drawn on the stone.

Having mentioned the above out of several different substances for drawing on, it will only be now necessary to deal with limestone as forming the foundation of all good lithographic printing. I will, therefore, proceed in my next paper to speak about the materials and tools necessary to the lithographic artist.

I may add that the art of lithography is one that admits of high artistic excellence, and that as it can be practised with success, and is in itself remunerative, it is well worth the attention of women, as a vocation from which a good living may be made.

## EAR-RINGS AND OTHER ORNAMENTS FOR THE EAR.

### PRINCIPALLY WITH REFERENCE TO THEIR MODES OF ATTACHMENT.

BY H. S. GOLDSMITH.

INTRODUCTION—MODES OF ATTACHMENT TO EAR—ANCIENT EAR-RINGS—TYPES OF FASTENINGS—FASTENINGS IN INDIAN WORK—EAR-RINGS HANGING TO FRONT.

*Introduction.* — The above limitation is necessary in order to keep this paper within reasonable space. It will deal with a few of the things an apprentice will soon be concerned with. These are the mechanical and technical portions, for at first the artistic merits of the ornament he has to do with will be out of his province.

If he is told to attach the hooks, etc., to the other parts that make up an ear-ring, and he has had a little previous consideration of the matter, it should follow that he will be able to turn out his work in a better form than would otherwise be the case. These reasons lead me to deal with the principles upon which the hooks and other fastenings should be made: first, in order to obtain the necessary security for the ornament; secondly, *in order to show the ornament to the best advantage* — or, in other words, to get them to hang or set properly when worn.

*Modes of Attachment to Ear.* — This kind of ornament attached by means of a hole pierced through the lobe of the ear, we shall find, gives us several classes of attachment, which we will at first divide into two—namely, those in the form of hooks or rings: that is to say, those usually understood by the name of ear-rings; secondly, those called ear-studs. The latter rest *on* the ear, while the former hang below it.

Here in England the ornaments are attached to the lobe only, but in some parts of India the ear is pierced in the upper part as well, in order to wear several pairs of ear-rings at one time; and in addition to that, the ear is sometimes slit and lengthened by wearing heavy solid ear-rings. On the outside of the slit, when the ear has become lengthened, there will be a piece of cartilage nearly as thick as a lead pencil, and this they use to clasp an ornament round, much the same that you would clasp a bracelet round an arm. These ornaments are about three-quarters of an inch long.

One can easily understand that the ladies over there do not mind large holes being made in their ears, as our ladies do, for it is a mere pin-hole in the ear that has to serve us for attaching the ornament, while there the happy jeweller can have a hole in the ear of any size, and in any part of the ear too. Seemingly this is a privilege we have lost, for in our museums there are plenty of so-called ear-rings which would require a slit half an inch in length before they could let the end of the ear-ring pass.

The other division will consist of ear-rings for unpierced ears, and there will be a little to say about them and their modes of attachment.

*Ancient Ear-Rings.*—The great number of modern ear-rings in which joints play a part is in complete contrast to those of the ancients in the British Museum, for there we find Egyptians, Greeks, and Romans taking full advantage of the natural ductility of fine gold, by bending or untwisting part of the ear-ring each time they wished to remove or attach the ornament.

A strong reason why we use joints so much is this:—The gold now worked is of a lower quality—generally very much lower—and all, or nearly all, of its ductility is gone, and in its place we have elasticity, so we cannot, even if we would, twist and untwist an ear-ring hook each time of wearing; for even if the gold would stand it without breaking, still it is not "kind," like fine gold, and would require pliers to turn the ends in with.

It would not be to our advantage to go back to fine gold for ordinary work, and the foregoing is written simply to draw attention to one of the cases in which a property or merit of the metal is used to its full advantage. In what follows we shall find that the elasticity of our present qualities is just as profitably employed as was the softness of fine gold in the old time.

*Types of Fastenings.*—With but few exceptions, most of the simple types of fastenings now in use are to be found at the British Museum, even to that which we now call the German hook; and so that there should be no mistake about the apparently topsy-turvy way this is worn, the Roman has kindly attached a pendant to it, and in so doing he has removed any doubts that we might have about it, as you can see for yourself in Fig. 1.

There are also a few specimens of a bird-shaped ear-ring (Fig. 2), in which the wire is fastened like the common facctted ear-ring (Fig. 3) which we all know.

In South Kensington are some like Fig. 4. This form seems to be made with but slight variation in Normandy, Germany (Bremen), Italy, and Spain, and its fastening is just the same as the Greek bird (Fig. 2).

Fig. 5, however, does not seem to be much followed. It is, as you see, in the form of a monster's head, with a tail formed by a coil of tapering rings. In many of them the spiral coil acts as some sort of a spring, and as a joint as well. This gives a fairly secure and practical fastening, and is used in India even at the present time. My rough sketch is taken from one as arranged in the cases at the Museum, but it would not hang in the ear like that, of course.

Fig. 6, you will note, is of a very strange form to us, although common enough in the East. This fastening possesses at least the merit of security: a state of affairs that can only be obtained this way with a fine gold pin, which, after passing through the pierced ear, is coiled round as shown in sketch.

*Fastenings in Indian Work.*—In Indian work the most general method of fastening an ear-ring, be it the shape of Fig. 6 or any other shape, or for ear-studs like Fig. 7 (this latter is drawn the actual size of many that are worn), is by means of a screw. These screws, of which the details will be shown when we come to bracelet fastenings—for they are too large for us to use for ear-rings—are obtained from double wire, coiled round a mandrel (piece of hard wire), one piece being soldered in a tube to form the female screw, the other being soldered on a peg to form the male screw.

The greater number of these screws run the other way to ours. Is this because the workman finds it comes more natural to him, just as we find a new hand will most likely chase his first screw in the lathe left-handed?

In India, also, is worn an ornament the size and shape of the ear, which is covered. The ornament is, however, perforated so that no serious impediment is offered to the wearer's hearing. Naturally the surface of such an ornament gives a good opportunity for display, and it is taken advantage of to the greatest degree.

They say comparisons are odious, and if we compare the size of ear-rings now worn

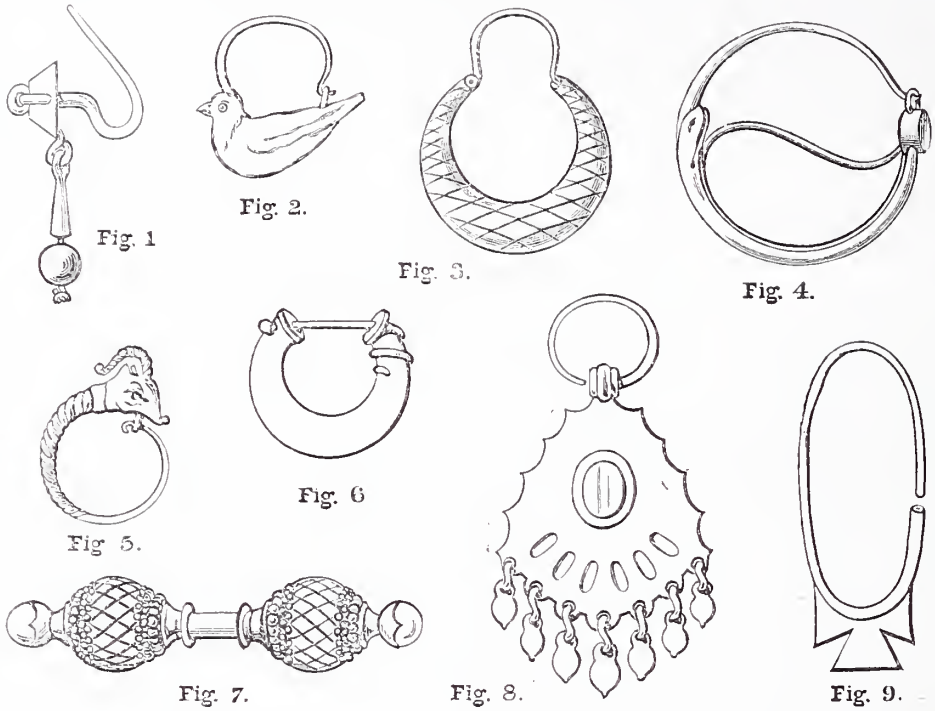

Fig. 1.—Ancient Roman Ear-Ring, with Wire the shape of the now-called German Hook. Fig. 2.—Greek Ear-Ring in the form of a Bird, the Fastening being the same as now used in Modern Jewellery. Fig. 3.—Modern English, with same class of Fastening. Fig. 4.—Modern Continental Form of same class of Fastening. Fig. 5.—Greek with Spring Fastening, the Tail acting as Spring. Fig. 6.—Greek, fastened in the Ear by threading through and coiling Spring round. Fig. 7.—Indian Ear-Stud: on Centre Piece is a Screw, to allow of separation of the End for Insertion. Fig. 8.—Russian Ear-Ring: Wire is attached the reverse way to show Edge and Back too much when worn. Fig. 9.—Sardinian, Ancient: also hangs contrary to the generally approved way.

to those of years ago, there seems to be a very decided tendency towards their gradual extinction. From a trade point of view it is to be hoped that this is not what it means; but as ladies do not in England wear rings in the nose, as some do in India, a mere decree of fashion will be enough to totally extinguish this class of ornament, and "the pearl in the Ethiop's ear" will be the only survival of a once flourishing part of our trade.

*Ear-Rings hanging to Front.*—Before entering on the particular sorts of modern fastenings, it will be as well for us to notice that although very much the greater proportion of ear-rings have their front to show to the front of the ear—that is, at right angles with the ear-ring hook—still there are just a few made to hang just the other way, and to show their edges, and possibly part of their backs, to anybody facing the wearer.

These exceptions are shown in Fig. 8 and Fig. 9, one Russian and the other ancient Sardinian—not but what plenty of others could be drawn, but these are sufficient to remind us that ear-rings are sometimes hung the other way; and to prove the rule which we seemed to learn at school is what exceptions were invented for.

As another curious fact about ear-rings, I may recall a statement made by a writer in a well-known magazine, "That at the time of the wars of Jugurtha it was the custom to wear one pearl ear-ring only, which afterwards became the sign of an acknowledged courtesan."

## A JOINER'S CRAMP AND HOW TO MAKE IT.

BY DAVID DENNING.

No joiner, cabinet-maker, or other artificer in wood but requires the aid of cramps, or, as they are often called, clamps. Comparatively little in the way of framing up can be done without them, and they are useful in a variety of ways—so useful, indeed, as to be indispensable. The amateur is addicted to the use of the best of everything if he has the wherewithal needful for the purchase; if he has not, then he must do without, unless he can contrive or make some substitute. If he can do this, he is still apt to think that he would turn out things of much better workmanship if he only had something nicer to work with. He would prefer to have an iron cramp, such as he will see for sale in the better class tool-shops, instead of the wooden affair commonly used by professional artisans. Perhaps he does not even know of the existence of these, for why should the dealer in tools proclaim the virtues of an appliance which any worker can make for himself, instead of recommending "the very superior article" which he has for sale? As to cramps, these are made of iron, either entirely or principally, and it would never answer the amateur's purpose to make them, even if he could.

I am led to make these remarks as, in the catalogue of a leading dealer who lays himself out to supply the needs of amateurs, several improved forms of cramps are named, but there is no mention of the kind generally used by practical men, although it is as good as any of the newest improvements, so called. As the young and theoretically far advanced young artisan is not above a similar weakness for fancy improvements, I may be permitted to offer him a word of advice to the effect that many a thing of venerable antiquity is quite as useful as the latest novelty. In saying this, I by no means wish to inculcate the principle of "what was good enough for my father and his father before him is good enough for me," for if we were all to act on it there could be no progress. On the contrary, when any new thing is calculated to save time or to facilitate improved workmanship, by all means adopt it. Whether the iron cramp has sufficient advantages over the older-fashioned wooden one to induce us to discard this is a question I do not feel called on to discuss with the small minority who think so. One of them, by the way, has told us in a lately published work that iron cramps are indispensable. Well, let those who think so use them, while others who know better use the equally efficacious cramp about to be described. It is no makeshift, but a good practical cramp, such as, with perhaps trifling variations, will be found in general use throughout Great Britain. As there is no better cabinet work in the world than that of this country so far as construction is concerned, it may readily be supposed that the native artisan does not employ inferior tools. Among these must be reckoned the wooden cramp. It is not difficult to make, and labour and cost will be well repaid by the result.

The form and details given are from some cramps which were being made a few days ago by one of the most experienced and able cabinet-makers with whom I am acquainted, and I know a few of them. I cannot say that cramps are any novelty to me, but when I see a good man at work I always like to watch his methods and what he is doing. My friend Thompson is not one of those narrow-minded men who would keep all his information to himself or those of his trade, under the erroneous idea that it is a mistake to let the outside public know too much; so when I said to him that, while I had been seated on a vacant bench near his, watching and chatting, the idea had come into my mind that it would be a good thing for the readers of this Magazine to be told how to make a really good cramp, he just replied—"All right, Mr. Denning, you can't do better than tell them about these I've got here." The thanks of the reader, therefore, are due to Mr. Thompson; for it may be taken for granted that those he was making were the result of as much careful thought as if an elaborate piece of furniture had been in question—that is to say, that the cramps would not have been made as they are if his experience had taught him that some little alteration would have made them more convenient or better in use. That the model is original in its details I do not say, but it is probably as good a one as could be found.

Fig. 1 shows the cramp, or rather a portion of it, for the bar is shortened off in order not to occupy undue space. In actual construction it can be extended to any reasonable length. All that is really essential to assist in understanding the construction is shown. On examination, the cramp is seen to consist of a bar the lower edge of which is serrated to form a series of stops for the sliding-piece shown on the right, while on the left is a fixed head with a screw through it.

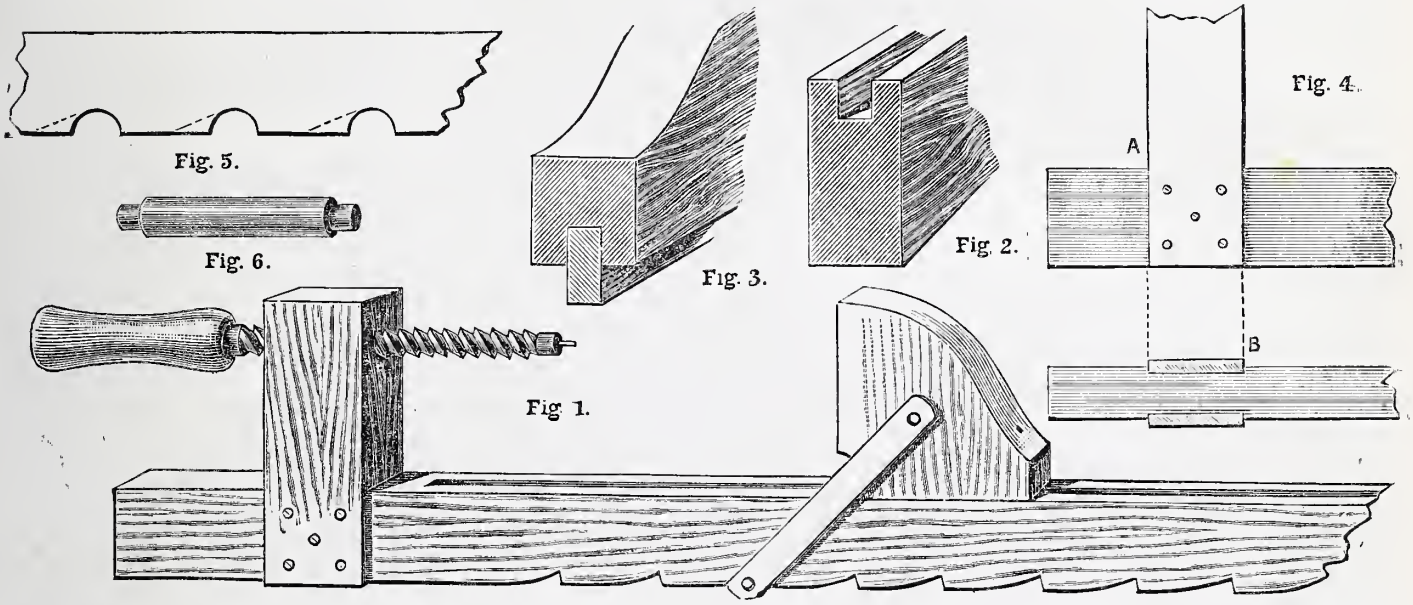

**Fig. 1.—Joiner's Cramp complete. Fig. 2.—Ploughed Groove in Bar. Fig. 3.—Tongue in Movable Piece. Fig. 4.—Diagram showing Mode of fixing Screw Block—A, Side Elevation; B, Plan seen from below. Fig. 5.—Diagram showing Formation of Stops. Fig. 6.—Pin connecting Iron Straps.**

The first thing is to determine the length of the bar, and this will depend on the size of the work that is contemplated. For general purposes about 3 feet will be found very suitable. If larger, the cramp is apt to be unwieldy, though it may sometimes be necessary to have them much longer. Any tough strong wood may be used, but nothing is better than oak, of which a piece of 1 in. stuff about 2½ in. wide will be required for the bar.

The sliding-piece must be of the same thickness. It may be about 4 in. wide and high. The shaping is purely a fancy detail, as for all practical purposes a square block of wood would answer just as well. It will, however, be noted that the grain of the wood is perpendicular instead of horizontal, or parallel with that of the bar, and the reason is that it may withstand the strain with the utmost of its strength when it is in use. The pressure is against the grain instead of with it.

Now, before proceeding further, the upper edge of the bar must have a groove ploughed along its centre, as shown by the sectional illustration (Fig. 2). The depth and width of the channel are not of importance. On the bottom of the sliding-piece a corresponding tongue will be inserted, as in Fig. 3. Those who prefer to do so may form the tongue from the block itself, but the better way is to do it as directed. It is now evident that the tongue acts as a guide to the sliding-block. The fit should be fairly easy, without being too loose to allow of lateral movement.

For the present this end may be left while attention is directed to the other. If several cramps are being made (and one, it will be noted, is by no means a sufficient number to have in a workshop, though in the amateur's workroom it will be better than none at all), it may be as well to get the holes threaded for the screws by the turner. If the maker has a box and tap for wood screws, he will of course be able to do what is necessary without further aid; but it is hardly likely that he will have them, and it may be satisfactory for him to know that he can do without either them or the turner by making use of handscrews. As these are obtainable at low prices at any tool-shop, there will be no difficulty in meeting with what is required. As there are two screws and two jaws in each handscrew, each of these will do for two cramps, and there is practically nothing wasted, although a piece of each jaw will be superfluous.

One of the jaws will do for the fixed block within which the screw of the cramp works, and some care will be required in fixing it to the bar, as at times there will be considerable strain on it. At first sight it may seem as though the bar is simply let into a mortice or hollow cut in the lower end of the block. This might do, but a moment's reflection will show that it will be better to make assurance doubly sure by partly sinking the block in the sides of the bar. It is then held as firmly as possible, and will withstand any strain of which the wood is capable.

Fig. 4, which is a diagram representing this part of the work, will make the construction quite intelligible to those to whom it might not otherwise have been so. When fitting this block, be careful to see that it is perpendicular with the bar, or, at all events, that the screw is parallel with it, and opposite to the solid part of the sliding-block. The fixed block is to be secured in its place by means of two or three screws, but these may as well not be inserted till the notches have been cut in the bottom edge of the bar.

It will be noted that these are not sloped off in a straight line, but that what may be called the teeth are rounded off instead of being carried at a straight bevel from point to point, as in a saw. The reason for this peculiar shaping, which undoubtedly entails more work, is that the points are stronger than they otherwise would be, for the wood runs to a considerable distance back from each. If we wanted to get the utmost possible strength, a series of half-round notches, as shown in Fig. 5, would suffice, but then the worker would labour under the disadvantage of not being able to slip the moving head backwards and check it so easily as at present. What is really done is simply, as it were, to round off the sharp edge at the front of each notch, as shown by the dotted line on the figure just referred to. The straight side of the other is, of course, the natural result of using the most convenient tool—viz., the saw—for making the cut. The points of the teeth may be about 2 in. apart, and the depth of the notch about ¼ in., or just sufficient to act as a stop to the pin connecting the strips of iron which confine the moving block.

There is nothing important about these pieces of iron either in thickness or width, and each maker may choose what is handiest to him. If it is all the same, he may as well use pieces of about the thickness of a shilling and about an inch wide. The proportionate length can easily be estimated by reference to Fig. 1. It must be understood that two of these pieces of iron are required for each cramp, and that they are connected by two pieces of iron rod. One of these engages in the notches, and the other goes through the sliding-block. In thickness the rods may very suitably be about $\frac{3}{16}$ in. to ¼ in. thick, but this is immaterial provided they are strong enough. At each end a shoulder should be turned or filed, the distance between the shoulders being exactly equal to the thickness of the bar. As cabinet-makers are not expected to be proficients in metal-working, Fig. 6 is a representation of one of these pieces of iron.

Holes must be bored through the thin pieces formerly mentioned to fit on to the ends of the connecting pieces, which can easily be fastened in place by riveting, but before this is done the hole must be made in the sliding-block and the iron pin run through it.

Having arrived at this stage, it will be seen that the sliding-block can be moved easily up towards the fixed head, but that when pressure is brought to bear on it from this direction the notches underneath prevent it being pushed back further than is desired. Its action is so simple that surely nothing more need be said about it.

The screw itself will be all the better of a little attention. The first thing that may be objected to about this, if it is a new one, is stiffness in working. This can easily be remedied by rubbing it with a mixture of ordinary blacklead and—no, not oil, for this is apt to cause the wood to swell, and so increase the defect we are trying to remedy—soft soap. This forms an excellent lubricant for the purpose, and may be a wrinkle worth noting by those whose wooden screws of any kind work too stiffly.

It will also be advisable to put an iron point at the end of the screw. Only a small one is necessary. If it projects ¼ in. it will be quite sufficient, and it should be sharp. The easiest way to make and fix the point is to screw a nail into the end of the wood, cut its head off, and then file down fine and thin. A piece of brass tubing put on the end of the wooden screw, the thread of which must be cut away for half an inch or so, completes the cramp, the manner of using which is so evident that nothing need be said about it.

A cramp made as described will be found quite equal for practical purposes to an iron one costing twelve shillings or more. "What will the cost of this wooden cramp be?" "Well, I can't say exactly; but if you wish to make one you can reckon this up as easily as I can, and from the same sources of information—viz., the tool-shops and timber-yards."

## HOW TO MAKE A QUARTER HORSE-POWER STEAM ENGINE.

BY F. A. M.

Introductory—Size and Power of the Engine—Time required to Make it—How to get Help when in Difficulty—A Comparison of Steam, Gas, Hot-Air, and Water Motors, with their Cost and relative Convenience—Work and Power, what they are—Power of Animals and of Man—What is a Man-Power?—What is a Horse-Power?—Connection of Engine with Lathe—Calculation of the Power of our Engine.

*Introductory.*—The engine about to be described is believed to be of convenient size for driving the turning lathe, etc., in an amateur's workshop. Although it is called a quarter horse-power, some would probably reckon it at a half horse-power; it might be either, according to the pressure of steam employed and the speed at which it runs. At any rate, it will be of about twice as much power as the amateur himself, and it will therefore drive any machine he could drive, together with the shafting required to convey the motion from the engine to the machines. The engine, too, is of a very manageable size, with no large or awkward work about it; anyone who has a 5 in. gap lathe will be able to do the whole of the work himself, whilst, if his lathe is of smaller capacity, he will probably be able to do all but turn and bore the fly-wheel.

The construction has been simplified as far as possible without interfering with efficiency, and the engine should be a really useful motor, which will wear well even when put to hard work. Besides, it will form an excellent opportunity for practice with lathe and tools and for learning some of the laws of mechanics.

Before going further, lest any reader should be led to undertake too lightly the task of constructing this engine, without having "counted the cost" in time and trouble, let us pause and consider what amount of labour we are about to undertake. It may, perhaps, be admitted that there is in the complete engine about £9 worth of labour by a workman whose time might be worth, say, 30s. per week of six full days of eight hours each. Now, 30s. per week is £3 per fortnight, and therefore £9 would pay for six weeks' work or thirty-six days, or 288 hours. Let us suppose an amateur would take 360 hours; then, if he works on an average three hours a day, it will take him four months, and if he works but two hours a day it will take him half a year. Let no one, then, begin with an insane desire to see the work finished, but let them first consider whether they will give the requisite time and trouble, and then work away steadily, determined simply to

do each part thoroughly well, and then there will not be many disappointments.

If a reader, having already acquired some little practice in the use of metal-working tools at the lathe and vice, still feels afraid to undertake such a piece of work, he may probably be able to get assistance in one of the two following ways. First, he may be able to find a small working engineer's shop within reach, the master or foreman of which would be willing to give him lessons for one or two hours at a time in the evenings, when work is over. One or two such evenings a week would be a great help to an amateur, who would bring the difficulties he had encountered in his work at home for explanation, and would profit by the extra facilities in the way of tools, machines, etc., afforded by the engineer's workshop, and learn thus how best to complete his own stock. Or, secondly, the amateur might call in a workman occasionally, of an evening, to teach or help him at home. Such lessons might cost from 9d. to 1s. an hour. Of course it will be our endeavour to make such assistance unnecessary by describing every process and operation as clearly as possible; still, there are always some things more easily learnt by a little "showing" than by any amount of description. The workman, however, should not be allowed to do the work himself, but rather to stand by and show the amateur how to do it.

*A Comparison of Workshop Motors.*—The steam engine is not the only motor the amateur may employ to drive his lathe. He may use a gas engine, a hot-air engine, or a water motor; and as each of these sources of motive power has its advantages and disadvantages, a word or two by way of comparison, to enable the reader to choose between them, may be acceptable at this point.

We begin, then, by comparing each of the forms of motor as to their first cost, and we will put the engine we are about to describe as worth (to buy) about £12, and its boiler about £12—say £24 complete. A *gas engine* of the ordinary non-compression type, such as the Bisschop, of two man-power, costs £33. It has no governor, and it may do tolerably well without. There is a small Otto engine in the market, with a governor, for £32, and it runs very silently, whilst the ordinary non-compression kind make a very disagreeable thump, not pleasant to have in a room in a house. A *hot-air engine* will run silently, but it is large and bulky; a quarter-horse costs £35. The *water-pressure engine* may be made with a cylinder and piston, or like a small water-wheel in a case, a jet of water being arranged to impinge upon the floats, like the "Thirlmere" of Messrs. Bailey of Salford. This last would cost but £3 10s., and it is very silent and easy to regulate by hand.

We will now compare the expense of running the four kinds of motor. That of the first three will be very small—about a shilling for a whole day's running. The water engine, however, if run from the town mains, will prove so expensive as to put it out of the question, except in those cases where there is a natural supply of water, under pressure, available.

There are two other considerations which we can take together—namely, in how much time can we start each motor, and how much attention will they require to keep them going? The steam engine here appears at a disadvantage: it will probably take twenty minutes to raise steam ready for starting, and all the while the engine runs, the workman must keep it in mind, and see that neither fire nor water gets low; for the first would cause a stoppage and the second might bring an explosion. Coal must be put on the boiler furnace about every fifteen minutes, and though gas may be employed for fuel, it would probably cost about four times as much to heat in that way. The feed-pump will be set to supply water to the boiler at about the same rate as that at which it evaporates, but this will not obviate the necessity of watching the water-level in the glass water-gauge, to make sure all is right. The *gas engine* can be started in a minute, and but for an occasional oiling it requires no further attention; it makes a disagreeable noise unless it be of the compression type, and that is expensive. The *hot-air engine* will require about fifteen minutes to heat up before it will start, after which it requires but little attention more than a shovelful of coal or coke every half-hour or so; it is bulky and rather expensive, but makes no noise. The *water-engine* is by far the best motor for the amateur; it has but one disadvantage—the cost of the water. With the usual price of 1,000 gallons of water at 1s., the cost of obtaining two man-power comes out about 2s. an hour—more than it would cost to employ two men to turn a wheel! But where there is a natural fall of water to be obtained, then by all means have a water motor: it has no smell, gives out no heat, requires no attention, makes no noise, is started and stopped in an instant, and if the workman left it running he would find it running still when he returned, provided it was not worn out!

In spite of all that has been said in favour of the other three motors, the steam engine is not to be despised. It is quieter than the gas engine, more compact than the hot-air engine, cheaper than either, and better understood; moreover, it can be made by the amateur himself. But, before we begin to describe its construction, we must first give some notions of

*Work and Power.*—"How many horse-power is it?" must, of course, be the question whenever we have to do with anything in the shape of a steam engine. But, first, what is a horse-power? "Oh, the power of a horse," people say, and they seem to fancy that if one took a locomotive of 100 horse-power, and tied 100 horses behind it to pull it back, that the two forces would be equal. But no, there is much more in the question; and we shall never grasp this expression unless we understand that horse-power, like man-power and every other power, *is composed of three elements.*

The *first* element is *resistance* or *pressure*, such as that of a weight.

The *second* element is the *space* or *distance* through which the resistance is moved.

The *third* element is the *time* occupied by the movement.

Suppose a man walk along the ground pulling a rope, and let the rope pass over a pulley and down a well, being attached to a bucket of water or other weight. Let us further suppose that the weight is such as to require all the strength a man can continuously exert. First, let him *stand still*, holding the weight suspended. What power is he now exerting? One man-power, do you say? No, indeed; no power is exerted nor any work done, because there is no distance moved nor space covered. Here we have only one element—resistance or pressure. Secondly, let the man now move slowly forwards, drawing up the weight as he goes, and what have we now? *Two* elements—pressure and space—and these two form *work* which can be measured, and is usually reckoned in *foot-pounds*. For instance, the bucket might hold four gallons of water, weighing together 40 lb., and the man might move forwards 10 ft.; then we should say he had done work represented by 400 foot-pounds. A foot-pound is the amount of work required to raise a weight of 1 lb. one foot high. To obtain in any case the number of foot-pounds of work exerted, we have only to multiply the weight *in pounds* by the space moved *in feet*. Notice, then, that the man would have done the same amount of work if he had raised 10 lb. 40 ft. high, or 1 lb. 400 ft. high, or 400 lb. 1 ft. high. Can we now reckon this work in horse-power or man-power? Not yet; for, observe, we might have told the man to exert his utmost strength and seen him pull up the weight in a moment; or we might say, "Take it easy," and have watched him, leaning gently on the rope, bring it up in a minute, when the power would evidently have been different. This brings us to the *third* element of power—*time*. Work is composed of only two elements, pressure and space; we cannot tell how much power is required to do a given amount of work unless we know in how much time it must be done. A man with a small pump can fill a tank as well as a steam engine if we give him plenty of time; in both cases the same weight of water will have been raised through the same space, and therefore the same amount of work will have been done, but if the work be done in one-tenth of the time by the steam engine, then the engine will have been exerting ten times the power of the man. It only remains to say, the element of time adopted is one minute.

When James Watt made his engines for raising water, it was stipulated that they should be able to do the work of so many horses. A steam engine is intended to produce power in return for a certain amount of coal, and, evidently, it is necessary to have some standard of comparison by which power can be measured; that standard is usually the *horse-power*—that is, the power required to raise 33,000 lb. one foot high per minute, which rule includes the three elements of weight, space, and time. It would amount to the same thing to say that a horse-power is the power required to raise 1 lb. 33,000 ft. high per minute; or, we might say, it requires one horse-power to do 33,000 foot-pounds of work in one minute. This is doubtless rather a high estimate of the power of a horse, which few horses could exert for more than three or four hours at a time; and here is inserted from "Molesworth's Pocket Book" another estimate of the power of the horse and of other animals (including the human variety), which they can exert continuously through an eight hours' day:—

| | Lbs. raised 1 ft. high per min. |
|---|---|
| Horse | 21,000 |
| Ox | 12,000 |
| Mule | 10,000 |
| Ass | 3,500 |
| Man, as in rowing | 4,000 |
| Do., on tread-wheel | 3,100 |
| Do., turning a handle | 2,600 |

3,000 foot-pounds per minute will, then, be about the power with which the amateur drives his lathe, going up to 4,000 for a short time when a hard piece of work must be done. As to what is a *man-power*, some allow five men to a horse-power, some six, some eight, and some ten. Until authority decides this point, we will assume to ourselves all the authority we can command, and state with the utmost decision that, so far as these articles are concerned, one man-

power is, and shall be, that power which is required to raise 4,000 lb. one foot high per minute, making it about equal to one-eighth of a horse-power; so that we may call our engine either one-quarter horse-power, or two man-power.

*Shafting required.* — An independent workshop motor, whether worked by steam, gas, hot air, or water, will involve shafting and belting to connect the motor with the lathe and other machines to be driven; and as a lathe should properly be arranged to run both ways, forwards and backwards, the shafting is not quite such a simple matter as might be supposed. One way out of the difficulty is to make the engine with a link-motion reversing gear, and to bring the strap from the engine straight on to a pulley on the crank-shaft of the lathe; but this pulley and strap would be most likely in the way, and as the turner would have to go to the engine to move the reversing lever, he would not have that instant control of his lathe to which he was accustomed when using the treadle, and might probably get disgusted with his engine and go back to the old plan, for want of proper conveniences in the way of connections. He must have perfect and immediate control of the revolutions of his lathe, and be able to start, stop, reverse, in an instant, without leaving his work, or he will go back, for ordinary work, to his treadle again. Another way to avoid the shafting is to attach the engine to the lathe direct, and one may often see nowadays a powerful tool in an engineer's shop with a little engine of its own attached to it to drive it, so that it can run when all the main shafting is still. It would not be wise to attach a steam engine to a small light lathe, but to a good strong 5-in. centre metal turning lathe an engine may be fixed, either outside the right-hand standard or under the bed over the right-hand crank, and, when fitted with link-motion and the reversing handle brought up to the workman's hand, it will form a very convenient arrangement—self-contained, and therefore easy to remove, under complete control of the turner—whilst any other machine, such as the grindstone, might be driven from a pulley on the crank-shaft of the lathe. Thus no shafting or belting would be needed, and the steam and exhaust pipes would be led round the back of the lathe from the boiler. The plan is inviting, and working drawings have been made of it as suited to the writer's own 5-in. gap lathe (by Milnes of Bradford). However, considering that a special case such as that would not be so good to begin with, and also that a horizontal engine of the ordinary type would be more generally acceptable, these plans were abandoned for the present in favour of the more usual form, though it will involve the requisite shafting.

*Calculation of the Power.*—If the previous remarks on horse-power have been understood, this will not be difficult. We must begin by ascertaining the three elements of power—Pressure, Space, and Speed.

*Pressure.*—The pressure which drives the engine is the force in pounds with which the steam presses upon the piston, driving it to and fro in the cylinder; it is estimated in pounds per square inch. We will adopt a *maximum* pressure in the boiler of 50 lb. per square inch, and we must not reckon on more than an average of, say, 30 lb. per square inch in the cylinder. It will probably require a pressure of about 5 lb. per square inch to overcome the friction of the engine itself. To allow for throttling by the governor, friction of the engine itself, and other small sources of loss, let us take the average pressure on each square inch of the piston to be 25 lb. Now, the rule for the area of a circle is, square the diameter and multiply by ·78; the diameter of our cylinder and piston is 2 in.: $2 \times 2 \times \cdot78 = \text{area} = 3\cdot12$, say 3 square inches. Multiplying 3 square inches by 25 lb., we get 75 lb. for the average pressure on the piston, and thus establish the first element of the power.

*Space and Speed.*—The other two elements, space and speed, we will take together; and supposing that the engine shall be regulated by the governor to run 150 revolutions per minute, and since the stroke is $4\frac{1}{4}$ in. long, during each revolution the piston will travel a distance of two strokes, or $8\frac{1}{2}$ in.; multiplying $8\frac{1}{2}$ by 150 revolutions, we get 1,275 in., which divided by 12 gives 106 ft. travelled by the piston in *one minute.*

Now, we have only to multiply together our three elements, 75 lb. × 106 ft. × 1 min., to obtain 7,950 foot-pounds per minute as the power, near enough to 8,000, which we have decided to call two man-power, and not far from $\frac{33000}{4} = 8{,}222$, the true quarter horse-power. One pound more added to the average pressure per square inch would raise the 7,950 to 8,408.

A simple rule to obtain the approximate effective power of a small engine, such as that with which we are dealing, would be: Multiply the speed of the piston in feet per minute by the total pressure on the piston, and the result is the power in foot-pounds per minute; divide this by 4,000 and we get the man-power; divide by 33,000 and we get the horse-power—the effective pressure on the piston to be estimated at from half the highest boiler pressure to two-thirds.

It is hoped that this explanation of the way to obtain the power of a small engine will prove so simple that every amateur engineer will thoroughly understand what work is, what is power, and how to calculate them. It only needs to be stated that we have been dealing solely with *actual effective* power and not with "nominal" power, which latter is an arbitrary or commercial term of no interest to the amateur.

## OXFORD FRAMES.

BY F. CROCKER.

SETTING OUT—REBATING—SIMPLE TOOLS FOR REBATING—CHAMFERING—PUTTING TOGETHER.

MOST wood workers, both professional and amateur, have at some period in their career tried their hand at Oxford frame making, and in most cases have found out that it was not as easily done as they at first supposed.

To make a good frame requires skill and taste, for, like everything else, to be satisfactory it must be made well, and the plainer it is made the better should be the workmanship.

The object of this paper is to describe a few varieties of the Oxford frame and how to make them (or at least how I should do it) without going into minor details, such as planing and sawing, which have been dealt with in other articles.

Having procured our timber we commence to make our frame. We will suppose, by way of illustration, that it is to be made of oak, for a picture 10 in. by 7 in. This will require four pieces, two being 14 in. long, $\frac{5}{8}$ in. by $1\frac{1}{8}$ in., and two 11 in. long, also $\frac{5}{8}$ in. by $1\frac{1}{8}$ in. I prefer Baltic to English oak for the purpose, as it is more easily worked, and in small pieces looks quite as well.

Face and edge, gauge and plane to size, then set out two pieces with a $6\frac{1}{2}$ in., and the other two with a $9\frac{1}{2}$ in., opening (this allows for a $\frac{1}{4}$ in. rebate); mark round each piece with the scriber or pencil (perhaps the latter is best, as the scriber, if not carefully used, leaves a deep mark, which has to be planed or scraped out) and square; put one on the other as shown in Fig. 1 and mark for halving, taking care that the members of the frame which are upright go right through on the face. Halve together in the usual manner, and we are ready for rebating.

Now, perhaps, a few words as to the easiest method of doing this will not be out of place. The best tool for the purpose (supposing we have no machinery) is a fence router such as a coach builder would use. One of these would cost from 4s. 6d. to 5s. 6d., therefore are out of the reach of the ordinary reader. Some use a rebate plane or fillister, but in that case the rebate is carried right through and filled up at the end by gluing a piece in after the frame is made. Unless the wood be very hard the rebate may be made with a cutting gauge. The ordinary cutting gauge will not be of much service for the purpose, but if the reader will make one as I am about to describe, he will find it useful for this and a great many other pieces of work where a stopped rebate is required. It will also be found useful for cutting off a number of parallel pieces of thin wood.

Procure two pieces of ash or beech, one 2 in. by $1\frac{3}{4}$ in. and $6\frac{1}{2}$ in. long (A, Fig. 2), the other $\frac{7}{8}$ in. by $1\frac{1}{8}$ in. and 6 in. long (B, Fig. 2). The sketch, Fig. 2, will describe the method of putting together; A is mortised to receive B, which may be driven backwards and forwards as in an ordinary gauge and fixed securely in any position by driving in the wedge, C. The cutter, D, is made out of a broken $\frac{1}{4}$ in. chisel or piece of steel, and is secured by means of a wedge shown in section (Fig. 3). A recess is made at E, Fig. 2, to allow the cutter to work close for a narrow rebate. It is rather an awkward-looking tool, but those who test its usefulness will pardon this. It is used as an ordinary gauge would be, but as the work is harder the tooth requires guiding with the finger and thumb of the left hand. In some cases you can take this piece completely out by gauging on both sides, but in others you have to use the chisel. A boxing router, or old woman's tooth, will be found useful for clearing out the rebate. A simple one, made out of a piece of wood and a chisel blade, is shown in Fig. 4. This is another tool which will be found useful for a variety of purposes, and will soon pay for the small amount of labour spent in making it. In fact, the rebate may be made with this tool alone by screwing a piece of wood on the face of it to act as a fence.

We now come to the most important part of our frame—viz., chamfering. Various tools are used for this, such as the drawing knife and spokeshave, but I prefer a sharp paring chisel, and a bull-nose or thumb plane. Some would use a pocket-knife and a bit of glass, but I hope the readers of WORK have got beyond that stage.

In Fig. 5 two of the commoner methods of chamfering are shown. Figs. 6 to 10 show various methods of finishing. Fig. 7 may be marked with a coin; the others will require a cardboard or veneer templet. In the centre of the rails a diamond is sometimes left (Fig. 6), or the pattern at the

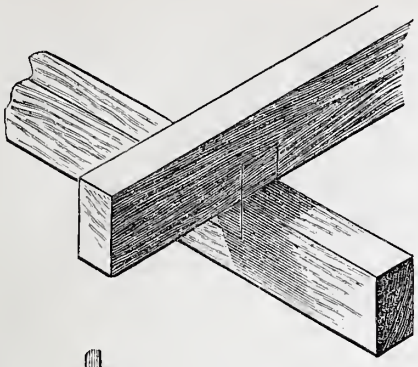

Fig. 1.—Diagram showing Method of setting out Halving.

Fig. 7.—Design for Corner of Frame.

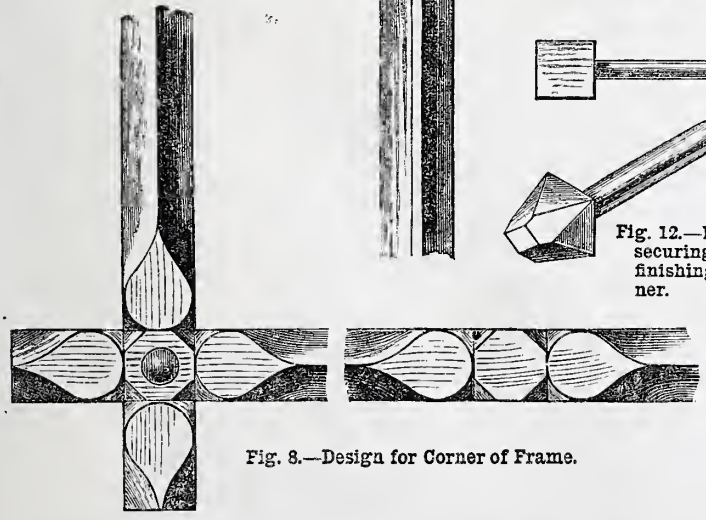

Fig. 8.—Design for Corner of Frame.

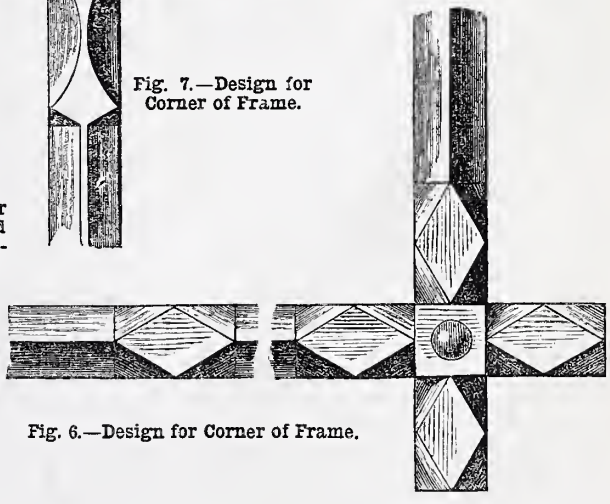

Fig. 6.—Design for Corner of Frame.

corner may be repeated (Fig. 8). Fig. 11 shows a method of varying the chamfer with a zig-zag made by notching a piece out on each side with the chisel. I merely give these as suggestions; other methods may be hit on without much trouble.

An important point in finishing is to avoid the use of sand-paper as much as possible, it takes the sharp arrises off, and makes the work look slovenly.

After chamfering, the frame may be glued together, but if you are not used to it glue has a peculiar knack of getting into the corners and leaving an unsightly brown stain.

For my own part I prefer putting the frame together, boring a $\frac{1}{8}$ in. hole in the centre of each corner, and fastening by means of a rosewood or black oak pin as shown in the sketches. This pin goes right through and is glued in. Fig. 12 shows the method of making this pin. The head is first made square, then the corners are taken off with a chisel. Occasionally a conical-headed one is employed, which may be turned. Different forms are shown in the various figures. Some finish the corners with a brass-headed nail, but I think this gives the frame a poor appearance.

I do not think it necessary to say anything about the final processes of varnishing and putting in the picture and back—these are minor details; but if there is any point on which I am not clear, I shall be happy to answer any questions in "Shop."

## MEANS, MODES, AND METHODS.

The Editor will be glad to receive communications for this department of Work. There must be few who, in the course of their experience, have not picked up many a hint and wrinkle which they have found to be useful to themselves in the prosecution of their respective trades or hobbies. Those who have thus got hold of "something worth knowing" are requested to make a note of it and pass it on, that it may be put into general circulation and so prove helpful to many.

### Reliable Cement for Lamps.

Powdered alum forms a simple, while at the same time thoroughly reliable, cement for attaching the brass rim to either glass or earthenware lamps.

The mode of procedure is as follows:—

(1) Thoroughly clean both rim and neck of lamp from everything of a greasy nature.

(2) Invert the brass rim, and fill its cavity with powdered alum, and place on the top of a hot range or stove.

(3) When the alum begins to get pasty (*not liquid*) with the heat, insert the neck of the lamp, press firmly into place, and remove the whole from stove, and set aside to cool. In about five minutes the lamp will be ready for use. The cement is thoroughly reliable, the oil apparently having no effect whatever upon it, and has the advantage over plaster of Paris that a lamp can be set and ready for use within five minutes, and if the vessel should meet with an accident, the rim can again be removed by re-heating, and adjusted to another vessel without all the trouble usually associated with such a job. W. H. W.

### Trueing a Buckled Circular Saw.

The following method I have seen used with success:—Immediately the saw commences to run wild, lift the wood you are sawing off the bench, and take a block of wood some 3 in. square, and rub the "end grain" against the side of the plate, moving it backwards and forwards with a firm pressure against the saw. *You must do it while the saw is warm,* so do not stop it.

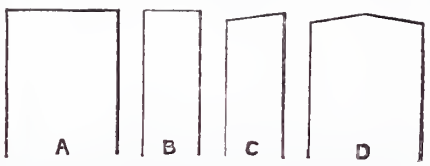
Turner.

### Boring Square Hole with Centre-Bit.

This is a workshop trick, and done in the following way:—Get a piece of stiff paper and fold it once, and put the folded edge up between two pieces of wood, say 1 in. thick, 3 in. wide, and 6 in. long. Pinch them altogether in bench screw, then with a centre-bit—say 1 in. bit—bore down (putting the point of bit into the paper between the wood) $\frac{1}{2}$ in. deep. On taking out paper and unfolding it, a square hole will be found in it. H. H.

### Trimming Flat Lamp Wicks.

As all those who burn oil lamps must be aware, a lamp wick of the flat variety should not be cut perfectly flat across, but should be slightly higher in the middle. To do this is generally a difficult task, especially



**Trimming Flat Lamp Wicks—A, Wick; B, Wick doubled before cutting; C, Wick doubled after cutting; D, Wick trimmed complete.**

after the wick has been some time soaking in oil; but if, instead of cutting it from side to side, the wick is first doubled down the middle and then cut through the two thicknesses towards the centre, a neat job will be the result. W. H. W.

## OUR GUIDE TO GOOD THINGS.

*** *Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of Work for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of Work without charge, the notices given partake in no way of the nature of advertisements.*

### 2.—The "Frederick Crane" Chemical Company's Specialities.

Both professional and amateur brass and other metal workers and finishers will be glad to hear of some new lacquers and substitutes for lacquers which, while fulfilling all the requirements of the old form of lacquers, are easier of application and superior in results. Such will be found in the specialities manufactured and supplied by the "Frederick Crane" Chemical Company, 22, Newhall Hill, Birmingham. The defects of ordinary lacquer are well known, and also the difficulty of applying it in many cases, especially on large surfaces, amateurs especially finding that after they have completed a nice piece of brasswork, the lacquering of it often presents an insuperable difficulty. The lacquers manufactured by the above firm are called "Zapon," Brassoline, and Ferroline. The most important of these is zapon. This is a perfectly colourless, transparent enamel, which can be applied either by "dipping" the article in it or by brushing it on in the same manner as ordinary lacquer, with the exception that heat is not a necessity. It sets perfectly smooth, and is very hard and not easy to scratch; it also has the property of drawing up its own drip. From experiments that I have made with it, I can confidently recommend it, and bear out the statement of the manufacturers that an amateur is more likely to make perfect work with zapon than a skilled workman with lacquer. It is also claimed that articles coated with this lacquer or enamel will stand any climate, are proof against flies or other insects, sea air, salt water, and noxious vapours—qualities which certainly recommend it as being most valuable for export trade. The prices of zapon are as follows:—zapon, for dipping (colourless), 21s. per gallon; brush zapon (colourless), 21s. per gallon; diluting liquid, 15s. per gallon; brush zapon (gold colour), 21s. per gallon.

Brassoline.—This is also a capital lacquer. It is worked like ordinary lacquer, but is superior to it in many respects. For instance, it will not cloud, however damp the atmosphere; it is perfectly waterproof; all brush-marks smooth out in drying; and the loss by evaporation is small. No heat is required, and therefore the novice can use it as well as the professional. It is made in several varieties, the most useful being gold, and antique brass. Price in each case, 12s. per gallon; thinner, 8s. per gallon. Short as is the time that these lacquers have been in use, they have gained a good reputation, being used by some of our leading firms in the brass goods line, notably Messrs. Benham & Froud, Evered & Co., Tonks, Limited, and many others, who speak highly of it.

Ferroline is a lacquer or preservative for ironwork and bright steel goods, useful for ironmongers and others who keep a stock of bright iron and steel goods, and who will appreciate an article that will obviate the necessity for the constant care and looking after that such a stock involves. It can be applied with or without heat, with a brush or by dipping. It is clear and transparent, and does not change the colour of the articles to which it is applied. Prices as follows—

| | | | |
|---|---|---|---|
| Ferroline, | Grade KK | per gall. | 12s. |
| ,, | ,, thinner | ,, | 8s. |
| ,, | No. 30 | ,, | 5s. |
| ,, | ,, thinner | ,, | 5s. |
| ,, | Grade HH | ,, | 5s. |
| ,, | ,, thinner | ,, | 5s. |

KK is the hardest and finest; No. 30 is not so hard, but has a heavier body than KK, and is especially designed for articles to be much exposed to atmospheric influences. HH is like No. 30, but thinner, designed for cheaper class goods.

Several other articles are also manufactured by the firm, amongst them being a Japan termed Negroline, in black and brown shades; Enameloid, a dead black for iron, brass, tin, or zinc; and Protectaline, a negative varnish for photographers. These I have not tried, but if they are equal to the before-mentioned, they will be found useful for those requiring such things. I might say that smaller quantities can be obtained, and should think that ironmongers and others who cater for amateurs and mechanics requiring such things would do well to stock these specialities.

### 3.—"Success, and the Way into It."

I have received a small pamphlet bearing this title from the Secretary of the Y.M.C.I.S., or, to give the name in full, the Young Men's Christian Industrial Society. Further, the address of the Secretary is 51, Old Bailey, London, E.C.; and from him all information respecting the Society and the establishment of branches may be obtained. It seems to be an attempt to bring about a combination of prayer-meetings and technical teaching as being, in the eyes of the promoters, the most likely arrangement to help our young men onwards and upwards. Surely there is a time for all things, and this being so, it seems neither desirable nor necessary to resort to this commingling of things sacred and secular. The promoters of the idea regard with suspicion the Volunteer Movement, Science and Art Classes, the Lecture Hall, the Club, the Public Bath, and the Gymnasium, as tending to deteriorate rather than improve young men. Most people entertain a contrary opinion.

The Editor.

## SHOP:

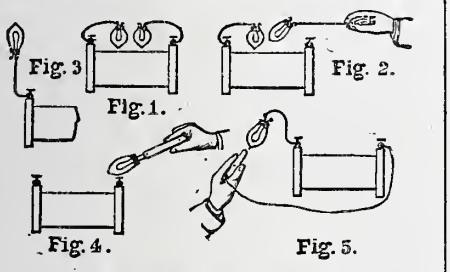
### A Corner for Those who Want to Talk It.

*** *In consequence of the great pressure upon the "Shop" columns of* WORK, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* WORK *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### I.—Letters from Correspondents.

**Experiments in Electricity.**—H. A. H. (*Tunbridge*) writes:—"The following experiments were published in the *Electrical Review*, and appeared originally in a foreign scientific journal:—(1) 'By attaching two curved wires—each supporting an incandescent lamp—to the terminals of the secondary circuit of a Rhumkorff coil (Fig. 1), we observe an approximation of the two lamps at the moment of the passing of the current. The phenomena is particularly marked at a distance between the lamps of from three to five millimetres. Care must be taken that the supports shall be very flexible, and for this purpose a copper wire one millimetre in diameter, and insulated with gutta-percha, will be very suitable. It is likewise important to avoid direct sparks between the lamp sockets. It is necessary to the attraction that there should be a discharge traversing the lamps and compelling the approximation. (2) By suspending one of the lamps (Fig. 2) and holding the other in the hand, the attraction between them will be the same. (3) A lamp placed upon the terminals of a Rhumkorff coil (Fig. 3) will become luminous, and it will be only necessary to approximate a lamp to a terminal to obtain gleams of equal brilliancy (Fig. 4). (4) Suspend a lamp by a flexible wire to one terminal (Fig. 5), and approximate to it any point in connection with the other terminal, and an attracted and sustained gleam will be observable.' Knowing that the current from the secondary circuit of a Rhumkorff coil partakes of the nature of frictional electricity, it occurred to me to try the experiments upon a Wimshurst influence machine, and I found that the experiments could be repeated upon it. Vacuum tubes can be shown also from a Wimshurst by connecting one end to one conductor, and the other end to the other conductor, and disconnecting the Leyden jars if it is found they retard the rapidity of the discharge. If instead of using the conductors they are taken away with the combs, the lamp will glow if held close to the glass plate while revolving. Vacuum tubes can also be illuminated by holding one end to the glass plate and taking hold of or touching the other end; indeed, the light ceases where the tube is held by the hand: it does not seem to make any difference to the illumination whether the platinum wire or the glass is held to the machine. I have also found that a momentary flash of light is obtained by rapidly approaching an excited glass or ebonite rod to a lamp or vacuum tube, and another flash by rapidly taking it away; in fact, a lamp or vacuum tube seems to act towards an excited glass or ebonite rod as a galvanometer does to an induced current in a closed circuit: upon approaching the rod there is a momentary flash, and all is dark; upon taking the rod away there is again a momentary flash and again all is dark. It is astonishing how little excitation a lamp or vacuum tube requires to make it show light; merely rubbing with an ebonite rod a piece of silk or a piece of cloth is sufficient. If you put either of them into an ebonite tube and rub the tube outside with any non-conducting material, they will show light, and after rubbing a minute or so, if the tube is tapped with the finger, they will light up opposite to where the finger touches. You may surround the vacuum tube with indiarubber, and place it in an ebonite tube, and the effects are the same as when the indiarubber is not there; the thickness of the dilectric does not appear to make any difference to the induction charges."



**Electric Lamps and Terminals.**

**Model Electro-Motors.**—Mr. George Edwinson Bonney writes:—"I regret that a mistake has been made in the illustration, Fig. 59, page 757, Vol. II., showing how to wind the F.M. cores of a Manchester dynamo. The winding on the right-hand core should be shown coiling round the core in the opposite direction to that shown in the illustration. I am very sorry such an oversight should have occurred, as I fear it will mislead some readers. Will you kindly publish for me an acknowledgment of my error?"

**Window Cleaning.**—H. B. S. (*Liverpool*) writes:—"Kindly correct two mistakes in my answer to C. T. (*Ashton-under-Lyne*) on page 766, Vol. II. of WORK. The first is a vital one to the question. Instead of 'hydrochloric,' read 'hydrofluoric;' and instead of 'H. B. B.,' read 'H. B. S.'"

**Erratum.**—In the reply to J. S. (*Aberdeen*), WORK, No. 109, page 780, on "Diamonds for Boring and Cutting Rocks," the word in brackets (carbonate) should have been "carbonado."

**H.P. Formula.**—W. H. T. (*London, S.W.*) writes:—"PUZZLED (see page 718, Vol. II.) has fallen into an error by assuming that P. in the formula he quotes is the boiler or initial pressure. It refers to the average pressure throughout the stroke, which depends upon the point at which steam is cut off. The point of cut-off in the stroke being known, the average pressure can be obtained theoretically by formula, and practically by taking an indicator diagram. The engine in question no doubt cuts off steam very early in the stroke, and the expansion is very considerable."

### II.—Questions Answered by Editor and Staff.

**Sheet-Iron Stampings for Dynamos.**—A. S. K. (*Sheerness*).—Sheet-iron stampings in any quantity may be obtained from vendors of dynamo castings, who will supply laminations for the armatures of dynamos made by them. The names and addresses of vendors of small castings may be found on pages 645, 678, and 766, Vol. II. of WORK. Write to any or all of these, stating your requirements, and ask for estimates.—G. E. B.

**Banjo Hoop.**—Banjo.—You might solder the ends of a piece of sheet metal together, making it the exact size of outside diameter of wooden hoop and cutting it a little wider than the hoop. Slip hook inside metal, then hammer the metal over the edges of wooden hoop: this is a very primitive method. A properly made hoop has the edges spun over steel wires; the wooden lining is put in afterwards, making it fit tight against metal hoop by using a mould of wood or metal and by cramps. See the Nos. of WORK for July 27, 1889; November 3, 1890; Nos. 70, 75, 79, 81, and 93 for other information. I can supply you with a hoop. You will find my address in the advertisement column.—J. G. W.

**Inspectorship.**—J. J. (*Argoed*).—The qualifications necessary to pass the examinations for an architect as required by the Royal Institute of British Architects are of a very different character to those required by the Sanitary Institute for an Inspector of Nuisances. From your letter I infer that, to a certain extent, you think the above studies are analogous, and that it does not matter which you pass, as it were, but you will at once see from the short description of the requirements of both institutions I give below that there is a vast difference between them. The examination of the Royal Institute of British Architects is divided into three stages to qualify the student as associate. Those for 1891 are as under:—First stage, or preliminary examination—to qualify for registration as probationer, R.I.B.A. Fee, one guinea. Occupies two days of about five hours and a half each, and embraces the following subjects:—(1) Writing from dictation. (2) Short English composition. (3) Arithmetic, algebra, and elements of plane geometry. (4) Geography of Europe and history of the United Kingdom. (5) French, German, Italian, or Latin; one language to be selected. (6) Geometrical drawing, or elements of perspective: either subject to be selected. (7) Elementary mechanics and physics. (8) Freehand drawing from the round. Second stage, or intermediate examination—to qualify for registration as student, R.I.B.A. Occupying two days of written examination and one day of oral examination. Fee, two guineas, on application with certain testimonies of study, accompanied by a certificate from a member of the Royal Institute, or other person of recognised position. This examination embraces the following subjects:—(1) The orders of Greek and Roman architecture, their origin, development, and application. (2) The several varieties of classic ornament. (3) English architecture from the Conquest to A.D. 1500, and the successive developments of the styles. (4) The characteristic mouldings and ornament of each period. (5) The nature of ordinary building materials, as stone, brick, tiles, timber, metals: and their qualities and defects. (6) The calculation of strengths of materials and resistance from data and formulas given. (7) The elementary principles of construction. (8) Elementary physics, as applicable to building. (9) Mensuration, land surveying, and levelling. (10) Plane geometry applied to actual work, projection of solids, and development of surfaces. Third stage, or the examination in architecture. To qualify for candidature as associate. Occupying five days. Fee, three guineas on application, with such probationary work as may be decided by the examiners. This examination embraces the following subjects:—History of architecture (to be illustrated by sketches). The leading characteristics and history of the principal styles of architecture. The special characteristics and history of any one of the following periods which the candidate may select, namely:—(*a*) Greek or Roman architecture; (*b*) architecture of Italy or France from the tenth century to the end of the fourteenth century; (*c*) architecture of Italy or France from the beginning of the fifteenth century to the present time; (*d*) architecture of England for some one century between the years 1100 and 1700 A.D. Mouldings, features, and ornament (to be illustrated by sketches):—As characteristic of architectural styles generally. As characteristic of the special style which may have been selected by the candidate in his probationary work. In this work the candidate will be expected to show a thorough acquaintance (graphical and historical) with the style and period selected by him, though such knowledge will not exonerate him from being required to show acquaintance with the details of other styles. The words "architectural style" may be understood as meaning Greek, Roman, Byzantine, Romanesque, one period of Gothic (English, French, German, or Italian), Renaissance, or one of the transitional varieties. Sanitary science, strength of materials, shoring, etc.:—Drainage, sanitary arrangements and requirements. The application of formulas for calculating the strength of materials. Shoring and under-pinning, and dealing with ruinous and dangerous structures. Plans, section, and elevation of a building:—The detailed arrangement of a building for a given purpose: as, for example, a parsonage for a town parish; a residence for a surgeon or other practitioner; a set of offices—to be filled in upon a skeleton plan (to a scale of ½ in. to a foot); a plan of one upper floor and of the roof, with details of the principal constructional arrangements; the section and elevation (to a scale of ½ in. to a foot), with constructional and artistic details to a larger scale. For the guidance of the candidate, a short statement of the requirements will be set forth. Materials, construction, etc.:—The nature and properties of building materials, including their decay, preservation, quality and strength, and their application in building. The principles of construction as applied in practice to foundations, walls, arches, vaults, roofs, floors, and partitions. Specifications and methods of estimating cost:—A specification of the work necessary in one or more trades for the building described above. Manner of specifying for other trades, and methods of estimating the cost of any building. Professional practice:—The general conditions usually appended to a specification and contract. The fifth day is devoted to an oral examination. Examination for Inspector of Nuisances:—Occupies a portion of two days, the first day being a written examination of about three hours, and the second an oral examination, with one or more questions, to be answered in writing if deemed necessary. Fee, three guineas if in London, but when the examinations are held in provincial towns, one guinea extra is charged. The examination embraces the following subjects:—The provisions of the Acts and Model Bye-Laws relating to the duties of Inspectors of Nuisances. A knowledge of what constitues a nuisance; methods of inspection of dwellings, cellar dwellings, dairies, milk-shops, markets, slaughter-houses, cow-sheds, and nuisances especially connected with trades and manufactories. The physical characteristics of good drinking water—the various ways in which it may be polluted by damage to supply works or in houses, and the means of preventing pollution. Methods of water supply. The characteristics of good and bad food (such as meat, fish, milk, vegetables). The Sale of Food and Drugs Act. The regulations affecting persons suffering or recovering from infectious diseases. The principles of ventilation, and simple methods of ventilating rooms. Measurements of cubic space. Disinfectants and methods of disinfection. A knowledge of the general duties of the office, and methods of keeping the necessary books and records. Writing and spelling. The proper conditions of good drainage. The advantages and disadvantages of various sanitary appliances for houses. Inspection of builders' and plumbers' work. Scavengering and the disposal of refuse.—E. D.

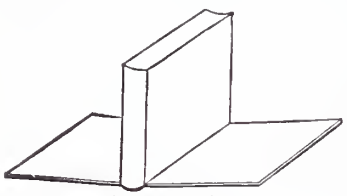
**Incubator.**—W. M. (*Plaistow*).—The well-piece of incubator as shown in the drawing (see No. 89, page 589) is open at bottom, and it is intended that the water of boiler should flow in and out—that is, rise and fall with the changes of the temperature. If you take the scale of the drawing it will give you the dimensions of the float sufficiently near.—C. M. W.

**Incubator.**—No. 305.—Full particulars of a simple and effective Incubator were given in No. 89 of WORK.—C. M. W.

**Villas and Cottage Plans.**—J. M. B. (*Dumfries*).—These, together with full detailed estimations, will be given in WORK as soon as opportunity offers, and some suitable writer and designer well up to the subject is forthcoming.

**Binding.**—Ruler.—Papers on the above appeared in Vol. I. Look them up and read them over. If you write to the publishers for the Index to Vol. I., you will be able to find out for yourself, and you can order the numbers from a newsagent, or direct from Messrs. Cassell & Co., Limited. However, I will try and give you sufficient information to enable you to do quarter-bound work in this column. I presume that it is cheap account-books you mean. The books are taken from the sewer, and if the end-papers have not been sewn on, the first operation is putting these to the book. This is done differently, according to the style of the book. We will suppose

for the sake of lucidity that we have a 3-quire foolscap, ruled special, with a printed heading. This is plain and tradesman-like; being a ruler you will understand it so far. The book has been sewn on three tapes or slips: this is the sewer's business, and you as a binder need not trouble why it is so. Now for the end-papers. You take two sheets of the same paper—these are left off by the ruler from the job—and fold them; next you lay them down upon a wrapper or waste sheet, and glue one page; you lift this and lay it upon the first page of the book, with the fold even to the back of the book, taking care that the slips are put back out of the way. You now glue the other sheet, and having turned the book, you put it down upon the last leaf in the same way. You must rub these down very carefully with the heel of your hand. The next operation is pasting down the slips. This is done by laying the book on the bench with the back towards you. Taking a little bit of paste on the forefinger of the right hand, placing the thumb of the left hand on the outside of the slip, you now rub the paste upon the inside of the slip, and with the thumb stick it down upon the book. The three on one side are treated in the same way; the book is turned over, and the other side done ditto. Now glue the back, and allow it to become nearly dry, taking care while gluing that the glue gets well in between the sheets or sections of the book. Now get two pieces of straw-board—about 2½ lbs. to the board will be heavy enough—the size of the book. Lay them down, and glue or paste them, and place them evenly upon both sides of the book, keeping them about ¼ in. from the back, and put the book in the press, between two pressing boards. I should have told you, just before putting on the boards, to give the book a few taps with the hammer along the back, but do not allow it to become round. After the book has become sufficiently pressed, which will be in a few minutes, take it out and ask the foreman to cut out a back for it. He will likely give you a strip of sheep or skiver. You take this and pare the two long edges of it, paste it, and having again glued the back of the book, you draw the back on as tight as possible, allowing as much of the leather to come over on one side as the other. A sheet marble paper is cut in two, glued, and put on the sides; it is now laid aside to dry, after which it is cut round, and the book is done. This is what is called quarter-bound flush. Quarter-bound, cloth sides turned in, is not much more difficult. In this case you will want four sheets for end-papers, and they will likely be sewn on; but if they are not, glue two of them as before, and put them to the book as already described, and tuck the other two inside of these by lifting up the first leaf of each. Paste down the slips, and glue the back as already directed. Cut the fore-edge now, and *round* the back in this case; cut the ends, and sprinkle or marble the edges. Now cut the boards, but this time you will have to cut them very exact. They should be ¼ in. longer than the book, and ¼ in. less than the book in breadth. This will allow them to project ⅛ in. all round over the book; this is called the square of the board, and will allow ¼ in. at the back for the joint as in the last-mentioned case. Put them on with paste as before, and press. The back that you will get to put on this time will be the same breadth, but about 1 in. longer. Pare it all round, paste it, and draw it on, gluing the back. After it is drawn on, it must be turned in. To do this, lay the book down upon the bench in the position shown in sketch. Hold the fore-edge tightly with the left hand, and with the thumb of the right hand turn in the leather to the inside of the board, breaking the end-paper to allow the leather to go into the back without creasing. When the other side has been done, shut the book, and rub the leather well with the folder to make it stick to the back, and rub the leather well into the joint. Now get two pieces of cloth for the sides, cut them evenly, glue them, and lay them up to the leather; rub them down with the hand, cut the corners with the scissors, and turn them in to the inside of the board. When the sides are dry, the end-papers are pasted up. This is easily done. Lift up one board, and paste the first page of the end-paper all over, shut the board, turn the book over and lift the other board, and paste the other end-paper; shut the board, and put the book into the press again. When it is dry, it is taken out, and your work is finished. —G. C.



Bookbinding: Position of Book on Bench.

**Shocking Coil.**—A. J. S. (*Edinburgh*).—Full illustrated descriptions of shocking coils will be given.—G. E. B.

**Medical Coil.**—W. B. (*Manchester*).—We have not yet given an article in WORK on "How to make a Medical Coil," but an illustrated description of one will be included in a series on induction coils. I do not know of a book giving the instructions you desire.—G. E. B.

**Screen.**—A. O. (*Manchester*).—You do not say what size you want to make the screen. Presuming the whole of the wood is to be covered, the framework may as well be of pine, say, 1 in. stuff. Set the wood out so that the three frames will be of exactly the same size. Either halve or mortice and tenon the joints, and if the screen is a high one it will be better to have a cross-rail about midway between the top and bottom. If you want the folds to move in any direction, you must use the "double-action" screen hinges, unless you are contented with canvas on webbing hinges—*à la* clothes-horse—to which I may refer you in case you do not know what is meant. If a simpler form of hingeing will suit, use ordinary butt hinges.—D. D.

**Fairy Bells to Piano Works.**—ADMIRER.—To make a fairy bells is perhaps one of the simplest musical instruments you can make. You require one to accompany the piano; therefore, you must have it tuned in unison with the notes on the piano. If you will kindly glance at the sketch (Fig. 1), you will find that the middle C is marked thus—X. This is the middle or pitch C on your piano, or is the same note as a C tuning-fork. This is the highest note on your fairy bells, and is consequently the shortest string; the other notes follow in rotation, first to the right, eight notes to C, then commence on the next bridge at B, and tune to the left seven notes with the longest string, C. Over the bridges you will find the sizes of the wire and the number of notes in brackets. Fig. 2 shows the top, which slides in a groove; Figs. 1 and 3 show how the string is adjusted, and Fig. 4 shows the loop at the end of string. Take a large sheet of paper and make it like Fig. 1, and bend it at the dotted lines at right angles, and you will see at a glance how the fairy bells are made. When you are perfectly clear as to how it is formed, commence operations. Make it of ⅜ in. pine; glue the side pieces (after grooving for the top to slide in) to the bottom, and drive a few needle points in to further secure it. Now make the bridges of beech; these are 1 in. in height, and 1½ in. wide. Glue these on after cleaning the bottom with glass-paper, and put three ¾ in. screws in each bridge from underneath. At the bottom end there is a bridge made of beech, 1 in. wide and 1½ in. thick; this is rabbeted out (see Fig. 3) so that the round-head screws go through that the wire is looped on, while underneath the bottom bridge is a slip of beech 1 in. wide glued on; this is a support to it, and prevents the liability to warp. When you have completed the woodwork, varnish the whole of it with two or three coats of white hard varnish, and bore holes for wrest-pins; you will need 1 oz. of each size wire: cost about 4d. per oz.—T. E.

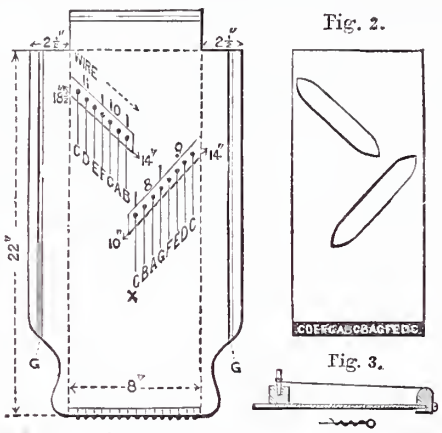


Fig. 1. Fig. 2. Fig. 3. Fig. 4.

Fairy Bells to Piano.

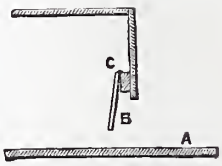
**Graph Composition.**—A. B. C. (*Wood Green*).—All graph compositions are much the same in their ingredients, though no doubt each manufacturer has his own favourite receipt which he is hardly likely to divulge. You will therefore understand how it is the exact composition of the graph you name cannot be given. The following is, however, an excellent recipe, and will no doubt suit you:—One ounce each of crushed loaf sugar and Nelson's gelatine, two ounces of sulphate of baryta, six ounces of glycerine, and four ounces of water. Melt the gelatine as if it were glue in the water, and while quite hot add the other ingredients, taking care to mix them thoroughly. When this has been done, pour into a shallow tray. When cold, the graph is ready for use. The great trouble will probably be caused by air-bubbles in the mixture; these must be removed by pricking before it hardens.—D. D.

**Lantern, etc.**—J. MCB. (*Sheffield*).—That a magic lantern worth £30 can be made for £5 by a beginner is doubtful, but with care you should make one that will be serviceable without incurring any very serious outlay. A good deal, of course, will depend on the way in which you buy your materials, and the amount of assistance you require. If you get the assistance of a carpenter, he will naturally have to be paid for his time, which may or may not be an important item in the cost of production. As you do not appear to have had much experience in mechanical work, you will find it better to attempt something simpler than a biunial lantern for a commencement. If you are inclined for joinery, as you seem to be, the construction of several easily-made articles of furniture has been described in WORK, and you would no doubt gain much profitable experience by making them. It is not easy to answer your second question satisfactorily, for you must be the best judge as to whether it is worth while to take lessons in carpentry to enable you to make things described in WORK, or not. If you have absolutely no knowledge of your tools or their manipulation, you would save time in learning them by taking a few lessons; but most of the descriptions are so full and lucid, that you ought to experience no great difficulty in following them. Naturally, you must not expect your carly attempts to result in anything very first-class. Should you resolve on going in for wood-working, you will find the articles on "Artistic Furniture" in Vol. I. well worthy of your study. They have been of great use to beginners. I am sorry to say that I do not know of any book on the penny whistle. For flageolet music, inquire of any music seller in your own neighbourhood.—L. I. P.

**Book on Metal Turning.**—LEARNER.—Apply to Messrs. Whittaker & Co., Paternoster Square, London, for the book on the above subject.

**Magneto-Electric Machine.**—MAGTELO.—The principal parts of the machine may be obtained from Messrs. F. C. Allsop & Co., 165, Queen Victoria Street, E.C.—G. E. B.

**Trap for Pigeons.**—W. B. (*Bridlington*).—The commonest arrangement for your purpose is a sliding door, pulled by means of a string. Of course, this requires to be watched, which is not always convenient, and the arrangement shown in the annexed diagram may suit you better. The pigeon alights on the outside sill, A, and enters the cot; in doing so, it has to pass the flap, B, which is made of light wicker-work, hinged at C with a piece of tape, and forms no hindrance to entrance; but, once in, the bird cannot get out again, as the flap will not yield to pushing from the inside. I lately saw a dovecot with every hole fitted with this arrangement, which the owner said worked well. In this case there were catches by means of which the wicker flaps could be kept up out of the way, if so desired. I may advise you in trapping pigeons to be careful not to get hold of anyone else's birds, or you may get into serious trouble.—G. LE B.



Trap for Pigeons.

**Bariquand Distance Register.**—KILOMÉTRIQUES.—I cannot glean any particulars respecting this make of distance register, but suppose from the exterior appearance of the engravings that it does not differ materially from others of its class. A train of wheels inside the instrument causes a set of discs to revolve before the openings in the sides or top of the case. These discs have numbers printed or stamped upon them from 1 to 0, and are speeded in the following manner:—The first disc records single revolutions of the actuating wheel up to 10. One revolution of this disc moves the second disc forward one notch, and this registers 10. When the second disc has made one revolution it moves a third forward one notch, and the three together then register 100. In this way any number of discs may be actuated. The actuating wheel is fixed in the nozzle shown at the side of the instrument, and this is moved by the wheel of the vehicle. The action is much like that of a gas-meter.—G. E. B.

**Current from Shunt-Wound Dynamos.**—C. N. (*London, S.E.*).—Taking up your line of reasoning, suppose we have a shunt machine capable of running 200 incandescent lamps of 16 c.p. The total output of the machine would probably be 11,200 watts. The maker of the machine would design it to give this output at a certain pressure, and would wind the fields with wire having a resistance calculated to balance the likely resistance in the lamp circuit. Whilst this resistance is maintained, a sufficient portion of the current will pass through the coils of the field magnets to magnetise them. If the resistance is lowered, an insufficient portion of the current will pass through the field magnet coils. If the resistance is raised, as by taking off part of the lamps, a larger portion of the current will go around the fields, and this will raise the E.M.F. of the current; but this cannot harm the lamps, because they resist the passage of current quantity (as expressed in ampères), and it is this more than E.M.F. that will destroy their filaments. Fusible cut-outs are inserted in lamp circuits to guard the lamps from accidental over-rushes of current.—G. E. B.

**Wheels for Back-Gear.**—R. T. (*Paisley*).—A wheel of 5¼ in. diameter and 60 teeth is not of the same pitch as a pinion of 2 in. diameter and 20 teeth; therefore, the wheels will not work together. Test this by dividing the number of teeth in each by the diameter:

$$\frac{20}{2} = 10 \text{ pitch}: \quad \frac{60}{5\frac{1}{4}} = \frac{60}{\frac{21}{4}} = \frac{80}{7} = 11\tfrac{3}{7} \text{ pitch.}$$

These are what is called the diametral pitches of the wheels—that is, the number of teeth for each inch of diameter. If the pitch, measured round the circumference, be the same in both wheels (as, of course, it must be if the wheels are to work together), then there must also be the same number of teeth to each inch in the diameter of both; whereas, in the case of the pinion there are 10, and in the wheel 11⅞. I find the detailed description of a 4 in. lathe in numbers 1121, 1123, 1125, 1128 of the *English Mechanic*; if you

obtain these four, you will have just what you require, including drawing and description of the nut for clamping the pulley to large gear wheel. I dislike this plan for a small lathe, and prefer to have a nut on the mandrel to the left of the small gear wheel, by means of which the pulley can be firmly screwed against the large gear wheel; you make a narrow cone fitting at the rims of both, and between their bosses on the mandrel you can place a spring washer to keep the rims apart when revolving separately. This requires no balancing, as the other does; it allows you to turn the inside of the pulley to equalise the weight all round; there is no looseness or rattle, and the front of the large gear wheel is left free to be drilled as a division-plate. The following wheels are suitable:—Wheels, 54 teeth, diameter, 5⅝ in. bare; pinions, 18 teeth, diameter, 1¾ in.; pitch on pitch line, $\frac{1}{12}$ in.; distance between centres, 3$\frac{11}{16}$ in.—F. A. M.

**Dividing the Circle.**—MECHANIC.—You propose to mark a plate off with dividers, and then centre-punch and drill; but remember your drill may "run," and not continue exactly on the spot where you first placed it. Dividing the circle is a very interesting subject, and many different plans have been adopted for doing the work accurately. If you have not already done so, I think you should read the papers in WORK, Nos. 10 and 14 of Vol. I., on pages 153 and 213. In the *American Machinist* of September 25th, 1890, is an extremely accurate method of originating a division-plate, but it is too long to describe in the "Shop" columns of WORK. Another plan is described in the *Scientific American* of March 8th, 1890, and of this I will try to give you an idea. Suppose you wish for a circle of 240 holes on a 10 in. circle: diameter being 10 in., the circumference will be 31·416 in., and the holes will be 0·1309 of an inch apart. Take a little block of steel about 1 in. wide, ¾ in. thick, and 1½ in. long, and file it so that its cross section will form a L (see Figs. 1 and 2); drill the two holes *a* and *b* 0·1309 in. apart, and fit a steel pin, c (Fig. 1), into one of them. Now obtain a strip of spring brass, say $\frac{1}{16}$ in. thick, ¾ in. wide, and about 30 in. long, one side of which must be fairly straight; lay the end of this in the angle of the L-piece, and, running the drill through one of the holes, bore it through. Now you can pass the drilled hole over the peg, run the drill through the other hole, and drill another; by keeping the edge of the brass close to the fillet on the L-piece, you get the holes parallel with the edge; continue drilling till you have made in the brass strip 241 holes, one more than the required number; thus you will have the holes *equally spaced*, and you can spring the band into a circle and put a peg through the first and last hole. To solder it in that position, we may chamfer the ends, and keep the peg in till the solder is set. Now you have probably guessed that we have only to turn a disc of wood so that the band of brass can be pushed on tight, and fixed with a few small screws, to get a pattern divided circle, from which our first row of 240 holes can be drilled. To drill any less number of holes for the other rows, cut the same band shorter, and use it again by turning down the wooden disc. You will, of course, have to mount your plate so that it will have to turn with the drilled band, and arrange a driller to act upon the plate while an index peg is dropped into the several holes. I say nothing about the form of the drill, shape of peg, size of holes, etc., because all that is treated at length in No. 10 of WORK.—F. A. M.

Fig. 1. Fig. 2.

**Dulcimer Wire.**—DEMENTED.—You can procure the wire necessary for stringing your dulcimer of Messrs. Chilvers & Co., St. Stephen's, Norwich (see page 645, Vol. I.). Steel wire will not do for the lower notes, as it is not heavy enough for the purpose.—R. F.

**Piano Wrest-Pins.**—J. H. (*Wednesbury*).—You should examine the wrest-plank or block as you name it, and see if it is sound and not split. If it is split, it will require to be renewed. If it is sound, you might try a little powdered resin in the hole where the pin is placed; if it is not very loose, this sometimes makes them grip if there is any grease that has found its way on the pin. But you should look at the bottom of the piano also, and see if there is anything pulling away. If they are very loose, and the wrest-plank is sound, procure a larger pin.—T. E.

**Musical Box.**—G. F. (*Walsall*).—In reply I shall be most happy to supply all additional information required, but I do not write to bring grist to my shop, as some do in a contemporary journal—such as engine models (the parts), telescopes and microscopes, etc., then offer the parts to fit up for sale. Wheels you can get cut to order, also main-springs, fans, etc., at any watch and clock material shop—of Cohen, Leeds; Barton, Liverpool; or Nicholson or Reid, Liverpool. But for a *new* comb or barrel you will have to send *number* of box to maker in Switzerland or Germany, as the case may be, choosing your tunes. Cost about 30s., and carriage for either comb or barrel. I am glad you are pleased with WORK—so am I. I am at present over three thousand miles away, hence delay in reply.—J. S.

**Prayer Desk and Chair Combined.**—F. U. (*Hereford*).—Your query for "a prayer desk and chair combined," certainly speaks of a good idea for something truly useful for the purposes required of it. It is a common mistake with some men that the possession of an idea is the completion of an invention. I have discarded many stray ideas indeed lately, simply because in putting them to practical test they were found to be unworkable in some respects. I mention this because some would have inserted in their letters such phrases as "this is my own idea," "I am sure the world will benefit," which you happily have refrained from doing. Only lately a trade acquaintance of mine was struck with an "idea." He commissioned me to work it out for him. His method, as was satisfactorily explained to him, was complicated and unworkable. After a few hours' hard study, I arrived at a very simple result—the simplest results *nearly always* require the hardest forethought—and it was acknowledged by him to be very useful for its purpose. A few days afterwards, however, I called upon him and found him very exasperated. Down in a lower corner, in very small letters, I had humbly inserted my name. Now, although his name was attached in very large characters as the intended manufacturer of the article, he was annoyed to think that he could not claim the whole honour of the invention, which he as good as told me he desired to do. He may, or may not, have worked the "idea" out without my assistance, but he was one of many of the kind who are greedy of things mental as well as material. You say you want something "wherein the back of the chair could be made to form the prayer desk whilst the seat would be used for kneeling upon." I am afraid it would be difficult to have a chair of ordinary height to answer the purpose if you wish to kneel upon the *seat*. This one could be made use of comfortably and conveniently if you kneel in front of it, resting your *arms* upon the seat. I presume this is what you mean; and I also suppose you want something with an ecclesiastical appearance. You could insert the desk part into a bought chair. The pattern is optional. If, however, you wish to make it completely yourself, have the seat 15 in. in front and 14 in. at back, 15 in. long, and 18 in. from the floor. Join the legs and back feet together by means of a narrow framing. Dowel the seat to the leg blocks as in Fig. 5. The back might be in one piece, connected to the back feet as in Figs. 6 and 7, so that a groove is left for the insertion of the back edge of seat, which should be shaped as in Fig. 8. The back can be from 16 in. to 18 in. high. Side sections of desk part are shown in Figs. 3 and 4; A and B will not be wanted very thick. You will see how they are hinged. If made as shown, all will lay quite flat when so desired, and can be instantly adjusted by drawing out the bottom end of A; that end of B which is at the top part of Fig. 3 falling down as in Fig. 4. To close it, push B upwards. For appearance' sake, have a moulding on the end of B which shows in front of chair. This will also be found very handy for keeping the leaves of the book down. You must have B long enough to allow it to project a little beyond the bottom edge of A as in Fig. 4. It must not fit too tightly, otherwise you will not be able to get it out of chair back. It is really a pity that correspondents will not give fuller particulars. I have presumed you are a member of some congregation; but it may chance that you are a leader or preacher. In the former case, this will suit you; in the latter, it will not be found so useful. If, however, you do not think this will suit, write again, stating, *as all should do*, everything that bears upon the subject.—J. S.

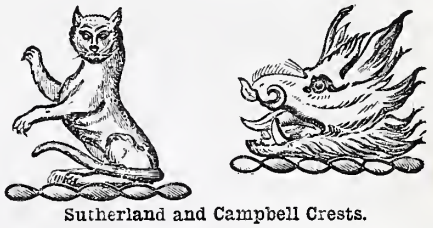
**Prayer Desk and Chair combined. Fig. 1.—Chair, showing Desk adjusted. Fig. 2.—Half of Back, with Desk closed. Figs. 3 and 4.—Sections of Desk down and up respectively. Fig. 5.—How to unite Seat to Leg Blocks. Figs. 6 and 7.—How to join Back and Back Feet. Fig. 8.—Back Edge of Seat. Letters show correspondence of Parts.**

**Hammered Metal.**—A. G. (*Hanley*).—Copies of the Milton shield are allowed to be sold in plaster, or in any other material, as the original is national property, placed in South Kensington Museum for the benefit of the nation at large. I have not heard of the antique head of Medusa being produced in plaster. If I were doing the job, I should purchase



Sutherland and Campbell Crests.

the head, and when done with, have it gilt, and try to dispose of it; you would then probably not be out of pocket by the transaction. I send rough sketches of the "Sutherland" and "Campbell" crests; could you not model from these? You would probably find it very difficult to obtain them either in metal or plaster of a suitable size for your work.—F. R. H.

**Æolian Harp.** — AQUILUS. — In tuning the harp the notes must be in *perfect unison*, not a shade difference either sharper or flatter. The exact note to which to tune it depends in a great measure upon the length of the string, but the best results are obtained from a low tension. For instance, if AQUILUS makes his harp 32 in. in length over all, which is the usual length, then the vibrating length of the string between bridges would be about 26 in., and this might be tuned to the note C, the third C counting from the bottom of the piano. The higher the tension—that is to say, the tighter the strings are—the stronger the current of air necessary to set them in vibration.—R. F.

**Water Delivery.**—TRYING.—There can be no reliable table, as the loss by friction varies with the length of pipe, but you will find it quite easy to calculate from the following formula:—

G = number of gallons delivered per hour.
L = length of pipe, in yards.
H = head of water, in feet.
D = diameter of pipe, in inches.

$$D = \tfrac{1}{12}\sqrt[5]{\frac{G^2 L}{H}} \qquad G = \sqrt{\frac{(15\,D)^5\,H}{L}}$$

The above is known as Hawksley's formula, and you will find it most correct.—T. W.

**Time Alarum.**—A. F. S. (*Stamford*).—Respecting the simple time alarum described by H. F. S. on page 699, Vol. II., a small electric bell quite good enough for the purpose may be bought for 4s. 6d., and this may be rung with current from a two-celled No. 2 Leclanché battery, costing from 3s. to 4s. more. These can be obtained from any dealer in electrical materials. Perhaps a local ironmonger will get them for you. The end of the switch-bar may be left uncovered, or the noise may be deadened with a bit of leather if you object to it.—G. E. B.

**Dynamos.**—J. P. (*Colne*).—The illustrations in my articles on "Model Electric Lights" are not drawn to scale; but in the illustrations of dynamos, the parts are shown proportionate. I have not attempted to show how the castings are made, because these are sold at a low rate by dealers, and it will not pay an amateur to make them. An amateur buying a set of castings need only know the particulars set down in the tables I give of their sizes. He need not know the dimensions

of the pole-pieces, nor the thickness of the web of the armature, as he will not have to make these parts. As a general rule, a dynamo will only give out half its designed current when driven at half speed. Double cotton-covered copper wire averages 2s. per lb. up to No. 22. Finer sizes command higher prices, and these may vary with vendors and districts.—G. E. B.

**Battery Carbons and Zincs.**—J. P. (*Colne*).—Select the carbon plates of a size to go easily into the jars, with quite ⅛ in. space between the edges of plates and sides of jars. The plates should be ¼ in. in thickness, and as long as the jars are tall. They may be obtained from dealers in electrical goods at prices varying from ½d. to 1d. per square inch. The zinc should be not less than ⅛ in. in thickness. The plates may be as wide as the carbon plates, but should be ½ in. shorter—that is, the bottoms of the carbon plates may well hang down ⅜ in. below the bottoms of the zinc plates. If your $\frac{3}{32}$ in. zincs are good and well amalgamated, they may be used in a chromic-acid battery, but will not last so long as plates made of thicker zinc.—G. E. B.

## IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**Paper for Screen.**—J. M. (*London, S.W.*) writes, in answer to SCREEN (see page 765, Vol. II.):—"I obtained a most suitable paper for the purpose at a much reduced rate from a wall-paper warehouse, the pattern of which had gone out of date, and have no doubt SCREEN would be able to do the same if he asked for an old paper, and gave the purpose for which he wanted it. Japanese paper is much too expensive."

**Pig-Scalding Tub.**—HAMMER AND DRIVER writes, in reply to J. G. (*Hull*) (see page 782, Vol. II.):—"If J. G. is not a cooper, I would advise him not to try his hand on a large oval tub, for there are hundreds of coopers that would fail in the attempt. The tools required are heavy and expensive, and of little service, except for coopering. Probably a bark or square would answer his purpose, and at the same time be much easier of construction. If so, he will find 6 ft. 6 in. by 2 ft. 6 in., and 2 ft. 4 in. deep, a nice size, inside measurement. It can be made of best red deal, free from shakes, sap, and dead knots, and must be dry. The narrower the boards, the longer it will last, boiling water having a tendency to warp deal. It should be bolted with iron bolts throughout, and the sides should overlap the ends about 3 in., and the ends be shouldered into the sides about ½ in. Make carcase first, being very particular as to joints being square and dead, and rush the joints from end to end. Rushes suitable may be had from any cooperage. They should be opened by inserting thumb-nail and drawing rush along, and spread out as flat as possible, but he must not grease them, as stated in a back number of WORK. Screw each part well together, levelling the joints with a piece of wood and heavy hammer as he proceeds. When carcase is together, he must be sure and true the bottom edges, for herein lies the making a good job. He should next make the bottom, allowing 1 in. over outer measurements; firmly bolt together, and true the side—that will be inside of bark; rush the bottom edges of carcase, and bolt bottom on to it; three pieces of scantling crosswise on bottom will lift bark of ground, and lend to its stability. A plug should be fitted as near to bottom as possible to empty, and his job will be complete. Being no draughtsman, I hope the above is sufficiently clear to J. G. without sketch. ⅜ in. bolts will be strong enough if a square does not suit him, and if he feels disposed to try and make an oak tub, and will repeat his question, I will endeavour to describe the making of an oak oval tub or kinmel."

**Hand-Power Circular Saw.**—W. G. (*Southport*) writes, in reply to S. P. (*Penarth*) (see page 782, Vol. II.:—"As a regular user of a circular saw, I would advise S. P. to abandon the idea of being able to cut 5 in. stuff on a circular saw bench, driven simply by manual power. My saw bench is driven by a ½ h.p. gas-engine, but even with the saw in the best of trim, it is very slow tedious work, cutting stuff 3 in. thick. If neither steam, gas, or water-power is available, S. P. would find a bench such as he wishes to make a disappointment."

**Soldering.**—B. T. W. (*Leeds*) writes, in reply to NORTHERNER (see page 734, Vol. II.):—"NORTHERNER should make his hard solder of two parts sterling silver, one part pin-brass or brass wire, taking care to keep his brass under weight. Melt on a piece of charcoal, drop on his work-board whilst hot, and flatten with iron stake. To make it thin for using in small pieces, I have found from experience that solders should not be rolled. NORTHERNER is trying rather a particular job when he goes in for soldering Geneva bezels, as most of them are little better than 9-carat, and as thin as tissue-paper. The best way is to spring the broken parts together—not bind it at all. Use borax in lump, rubbed on a bit of slate wetted with water, and use sparingly on part to be soldered only. The secret of hard soldering is knowing what heat the article will stand before melting, and that can only be come at by experience."

**Curing Skins.**—W. N. (*Tottington*) writes, in reply to IDEM SONANTIA (see page 631, Vol. II.):—"First see that the skin is fresh; put it into cold water for twenty-four hours; and if it is full of blood, put ½ pint of salt in. Then take out and flesh it—that means, take the inside skin off altogether—not fat altogether, for there is a second skin to all skins which must come off, or you cannot cure it to be soft. When this is done, for rabbit or hare or cat skins, take ½ lb. alum and ½ lb. salt, and boil in one quart of water; then let it cool down until lukewarm. Into this put your skin—for a small skin six hours is long enough—then take out and hang up to dry, and as it dries take it down and keep ratching it all round, and you will come at it in time."

**H.P. Formula.**—BRASS writes, in reply to PUZZLED (see page 718, Vol. II.):—"I do not see how you get your formula to work out to about 200 h.p. I make it come over 1,000 h.p.; but this is due to an error in your formula. You have omitted, in your formula, to take into account that the stroke should be calculated in feet, not in inches. Units of work are calculated in feet, and to do this in your formula 75 would have to be substituted for the 9 in. in the numerator, or 12 have to be multiplied into the denominator, thus:—

$$\frac{2 \times 78{\cdot}54 \times 9 \times 80 \times 350}{33000 \times 12} = 99{\cdot}96,$$

bringing the h.p. down to 99·96. There is still a great difference between the brake h.p. and the h.p. as above. How this is to be accounted for is hard to say, but is the 80 lb. pressure the pressure in the boiler or the mean pressure in the cylinders? If it is the pressure in the boiler, then the mean pressure in the cylinders would probably not be more than 50 lbs.; but it is useless guessing at it. The only way to get the correct mean pressure is to have the engine indicated (the process of which a very good description was given in 'Shop' a few months ago). If 80 lbs. is the mean pressure, then, as the song says, 'there's something gone wrong with the works,' or the brake test is not correct. The indicated h.p. will always be greater than the brake h.p., and the ratio between the two is called the 'modulus,' or the efficiency of the machine. The one may be termed the gross power and the other the net power, the difference between them being due to friction, leakage, or other causes."

**Paint for Tickets.**—J. H. (*Monkwearmouth*) writes, in reply to A. J. S. (*Moseley*) (see page 601, Vol. II.):—"If A. J. S. intends going in for tin ticket writing, he will do well to try the following plan:—After getting the tins ready, give them a coat of 'medal brand' or 'Foochow' enamel. I have not tried the latter, but the 'medal' I always use myself for white tickets; they require two or more coats of enamel. A white ticket, black figure, and French grey shading, with a black line round outside edge, is the best. A dark ticket with white enamel figures never looks well. The best job is always the white ticket and black figures. Tin tickets, as a rule, do not pay, as tradesmen will not give a proper price for them. We do as few as possible of them. If A. J. S. wants any more information, I will tell him to the best of my ability. I send a specimen ticket to the Editor done with the enamels. The above makes a better job of them than dipping them in varnish colour, and letting them drain. Will any of the numerous readers oblige me with instructions for making a machine for cutting cardboard? as cutting it on a table hacks the table top all to pieces."

**Transparlcum.**—L. E. (*London, E.C.*) writes, *re* inquiry by C. E. H. (*Horwich*) (see page 734, Vol. II.) in WORK about "Photography":—"Your correspondent probably means 'Transparleum.' The method is as follows:—Paste the photo (unmounted) on the concave side of a crystoleum glass; rub it down with sand-paper on the back till all the paper is removed, but without scratching the film that bears the photo; cover this film remaining on the glass with spermaceti wax, evenly rubbed on, and then paint with oil-colours. The background, flesh tint, hair, etc., should be painted on another glass, which is then placed over the first, and the two joined together at the edges by strips of paper. Do not forget that all the work is done on the concave side of the glasses."

**Plate Rack.**—C. B. (*Tonbridge*) writes:—"On seeing your answer to J. N. (*Erith*), No. 102, page 812, regarding rods for plate rack, I venture to think a plan of mine may prove acceptable to some of your correspondents. Instead of using wood rods, which are apt to rot, I tried bamboo canes, usually sold for flower stakes; they are about 4 ft. long, and cost about 2s. 6d. per hundred, and I have found the plan most successful."

**Violin Materials.**—M. (*Bishop Auckland*) writes, in reply to J. E. (*Chatham*) (see page 814, Vol. II.):—"You can obtain violin materials and tools from Mr. Hill, 72, Wardour Street, W. I believe there is a book on the subject, published by Messrs. Ward and Lock."

## V.—BRIEF ACKNOWLEDGMENTS.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—A. K. (*Edinburgh*); AN ARDENT READER; W. G. (*London, W.*); F. P. (*Tottington*); J. H.; DECORATOR J. W. (*Manchester*); T. P. J. (*Manchester*); A. J. A. (*Rouen*); A.W. (*Exmouth*); CONTRIBUTOR; APPRENTICE MASON; M. J. C. (*Glasgow*); AMBIDEXTER; J. M. (*Manchester*); HOOP-BENDER; B. C. (*Nottingham*); J. K. (*Leeds*); RAINFORD; UBIQUE; H. G. W. (*Bath*); E. D. S. (*Rye*); J. W. M. (*Halifax*); J. D. (*Holyhead*); WAX; T. R. B. (*Blaydon-on-Tyne*); WANTS TO KNOW; W. J. (*London, N.W.*); SHOEBLACK; F. E. H. (*Islington*); A READER; HORA; J. M. (*Newcastle-on-Tyne*); LIVERPOOL; A. F. (*St. Leonards-on-Sea*); J. W. R. (*Westminster*); X. L. U. M. (*York*); D. R.; TERPSICHORE; DRAUGHTSMAN; A. C. W. (*Bermondsey, S.E.*); R. J. A. (*Seacombe*); TYRO; R. S. E.; S. L.; M. P. (*London, S.W.*); F. W. S. (*London, W.C.*); GRADUATE; C. A. O. (*Chatham*); H. J. W. (*Romford*); F. C. P. (*London, W.C.*); J. G.; G. (*London*); CONSTANT READER; A PLASTERER; DELTA; GLENIFFER; J. L. (*Somerton*); BLACKSMITH; F. S. (*Manchester*); H. S. (*Liverpool*); OLD SUBSCRIBER; J. N. (*Surrey*); JOINER; A. T. (*Nottingham*).

VOL. III.—No. 107.] SATURDAY, APRIL 4, 1891. [PRICE ONE PENNY.

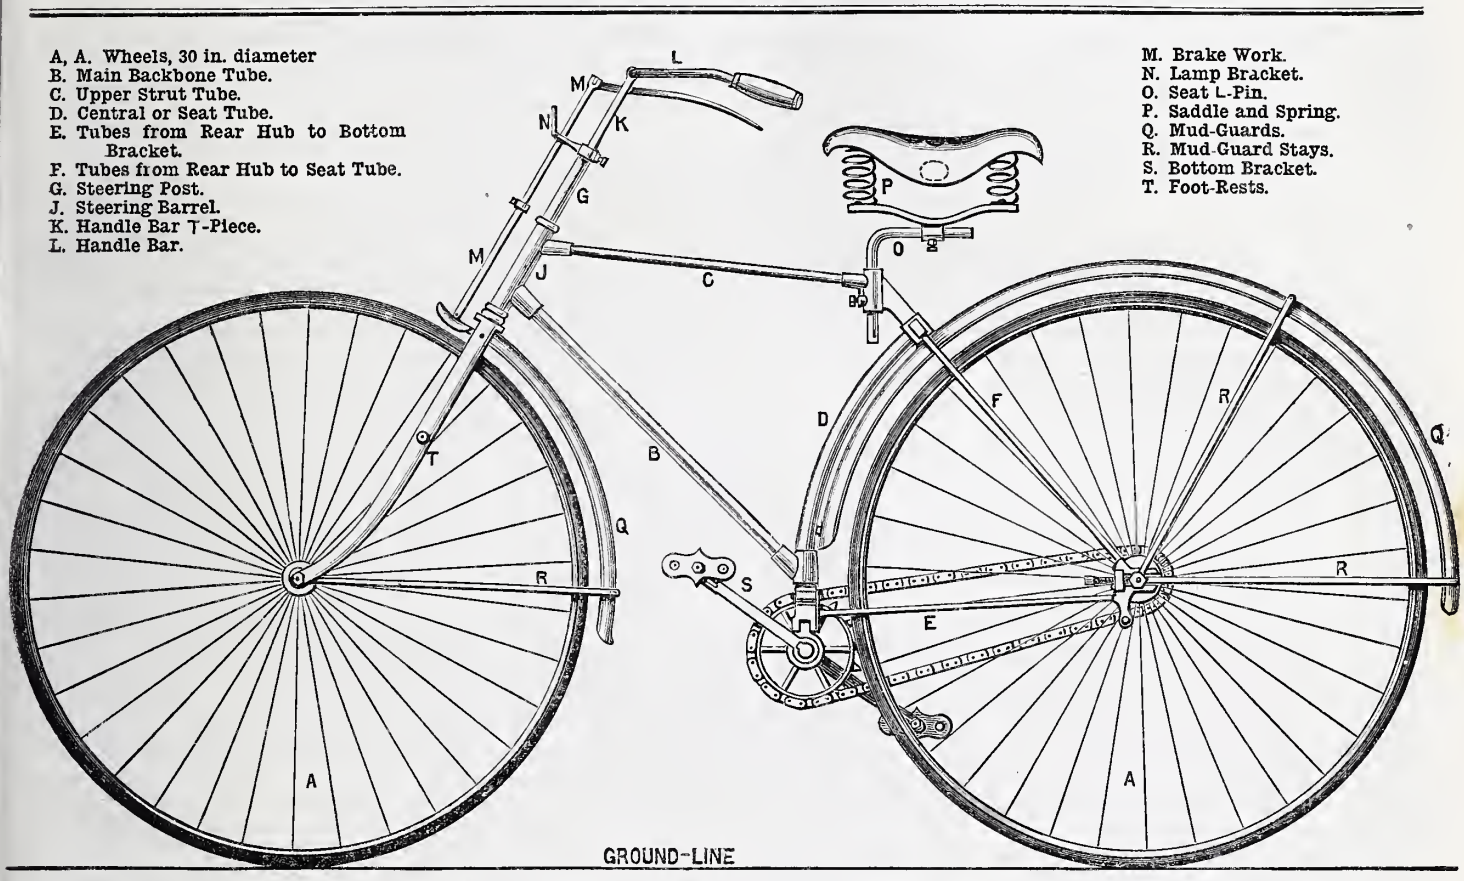

Fig. 1.—Diamond Frame Safety Bicycle. (One-tenth full size.)

### THE SAFETY BICYCLE: ITS PRACTICAL CONSTRUCTION, ETC.

BY A. S. P.

INTRODUCTION—DESIGN AND PARTS—MATERIALS—WHEEL HUBS—SPOKES, ETC.—SOLID PARTS—PARTS THAT MAY BE PURCHASED—SPEED—RULE FOR GEAR-UP—NECESSARY TOOLS—LATHE—FORGE—ANVIL—VICES—GRINDSTONE—SCREWING TACKLE—RATCHET BRACE—SMALLER TOOLS—HOME-MADE TOOLS—LATHE CHUCKS, GAUGES, ETC.

*Introduction.*—It is proposed in a series of papers to describe the practical construction of the pedo-motive machine now well known as the "Safety Bicycle."

It may be inquired in the outset, Whence the name safety bicycle? for there is no bicycle—or tricycle either, for that matter—absolutely safe. The bicycle so called is only safe by comparison with that known as the "ordinary," and in that comparison it is certainly very much safer; but an absolute safety bicycle is not yet in existence, nor is it ever likely to appear. However, the name has become conventional, and we must stick to it in describing what we call the "Diamond Frame Safety Bicycle."

It is a curious fact that the original bicycle, with its wooden wheels and iron tyres, bore a striking resemblance to the modern safety: it had nearly equal wheels, from 30 in. to 36 in., connected by a backbone and fork similar to the modern cross frame; it was driven with cranks on the front wheel, and was not geared up; whereas the modern safety is usually driven by cranks and chain from the rear wheel, and may be geared up to any extent.

*Design and Parts.*—I propose describing a machine of my own design and make, and while the frame bears a general resemblance to many, it is different from any known to me. A reference to the accompanying drawing of the complete machine will show this, and that the frame exactly as it is shown is "not to be found in any of the books." There are several details which I claim as good things, and which will be described in due course. The drawing of the machine here shown—which I may say, for convenience of illustration, is one-tenth full size, or on a scale of $1\frac{1}{5}$ in., or 1·2 in. to 1 ft.—will be frequently referred to in future papers. The reader, therefore, who essays to construct his bicycle from the instructions given in this series would do well to keep the part of WORK containing the drawing at hand, or make an enlarged drawing from it, or, better still, a full-size working drawing on a board about 4 ft. 6 in. by 3 ft. 6 in., and lettered or figured for reference. In the drawing Fig. 1 the various parts of the diamond frame safety are as follows:—A, A, two wheels: in this case 30 in. diameter; B, main backbone tube; C, upper strut tube; D, central or seat tube; E, two tubes, one on either side, from rear hub to bottom bracket; F, two tubes, one on either side from rear hub, joining seat tube D at junction of upper tube C; G, steering post joined to the crown of the front fork H; J, steering barrel, either fitted plain on to the steering post G or having balls at both ends—in this machine it will be shown in detail fitted with cone surfaces; to this barrel are attached the two tubes B and C; K, handle bar T-piece, made to adjust by sliding freely in the steering tube G; L, handle bar, with horn handles; M, brake work, consisting of lever under handle bar, spoon immediately over the wheel tyre, and connecting tube and rod; N, lamp bracket; O, seat L-pin; P,

saddle and spring; Q, mud-guards; R, mud-guard stays; S, bottom bracket, which carries the driving shaft, chain wheel, and cranks; to this bracket is attached the tube B, and also the two tubes E; T, foot-rests, one on either side of the front fork.

*Materials.*—Having named the *principal* parts of our machine—for it will hardly be credited that in a machine of this sort there are over 320 parts, counting the chain as one part—we may now turn our attention to the materials of which these parts are composed.

*Wheel Hubs.*—The wheel hubs are gun-metal, having steel caps fitted in the ends where the balls run. The pins, or axles passing through these hubs, are steel, and are fitted with hollow cones. These cones and the caps, together with the balls, are all made very hard, so as to stand wear.

*Spokes, etc.*—The spokes are of best steel wire, specially made for this purpose. The wheel rims are crescent steel or hollow steel, as the case may be. Rubbers best red or grey.

*Solid Parts.*—The solid parts, such as bottom bracket S, steering barrel J, and C, are steel stampings or malleable castings. The L-pin O is a bit of round steel bar $\frac{5}{8}$ in. thick. All the tubes are weldless steel, 18 Birmingham wire gauge. The mud-guards are made from light sheet steel rolled to size of wheels, and hollow in section. The mud-guard stays are light rods, either round or flat, as may be preferred. The front fork is hollow weldless steel tapered and curved at lower ends, and joined to a crown piece at their upper ends.

*Parts that may be purchased.* — The following parts are usually purchased ready made from makers or dealers:—Hubs, to be bought bored, tapped for spokes, and plated; cranks and pedals, finished and plated; chain in lengths; saddle and spring, or both in combination; horn handles; rubbers for tyres, pedals, and foot-rests. Then the accessories are lamp, tool-bag, spanners, oil-can, etc.

It may be mentioned that hubs can be bought in the rough, and fitted up by the mechanic himself; and the same with bottom brackets, pedals, cranks, etc.

*Speed.*—It is a puzzle to many non-mechanical minds how the safety bicycle, with its small wheels, usually 30 inches, can be so speedy as the large-wheeled ordinary, for it is a fact that many people cannot be made to understand how the chain in combination with two different size wheels has the property of gearing up the small wheel to equal its big brother of the ordinary. Of course, anyone with but a small modicum of mechanical brain can see it. It is also a fact that thousands of riders of the safety can tell you what their own machine is geared up to, because the agent or maker told them, but they cannot by rule of arithmetic demonstrate for themselves the gear-up of their machine. The rule is a very simple one, as will be seen presently, and I insert it here for the benefit of those to whom it may be useful.

*Rule for Gear-up.*—The rule is to multiply diameter of driving wheel by number of teeth on chain wheel (that is, the wheel that is mounted on the bottom bracket shaft), and divide result by number of teeth on chain wheel of rear hub. Say the driving wheel is 30 in.; teeth on large chain wheel, 18. Multiply 30 by 18—result, 540. Divide 540 by 9—answer, 60. Nine is the usual number of teeth on the hub chain wheel, and in the following three examples 9 is used as the divisor:—

(1) Driving wheel .. .. .. .. 30 in.
Large chain wheel .. .. .. 18 teeth
Hub chain wheel ... ... .. 9 „
Then $\overline{30 \times 18} \div 9 = 540 \div 9 = 60$ in.
The machine is geared up to 60 in., or double that of the 30 in. wheel.

(2) Driving wheel .. .. .. .. 30 in.
Large chain wheel .. .. .. 16 teeth
Hub chain wheel .. .. .. 9 „
Then $\overline{30 \times 16} \div 9 = 480 \div 9 = 53\frac{1}{3}$ in.
In this case the machine is geared up to $53\frac{1}{3}$ in.

(3) Driving wheel .. .. .. .. 30 in.
Large chain wheel .. .. .. 14 teeth
Hub chain wheel .. .. .. 9 „
Then $\overline{30 \times 14} \div 9 = 420 \div 9 = 46\frac{2}{3}$ in.
In this case the machine is geared up to $46\frac{2}{3}$ in.

If you continue reducing the number of teeth in the lower or forward chain wheel, keeping the hub chain wheel the same—namely, 9—you are gradually lowering the gear. Bring down the number of teeth till both wheels have the same number, 9, and of course the machine is not geared up at all, and is what is called geared level. Multiplying a sum by 9, and dividing the result by 9, leaves the sum just as it was—thus, 30 in. $\times$ 9 = 270, and 270 $\div$ 9 = 30.

The above rule is easily carried in the memory or in a note-book, and anyone can easily tell the speed of a machine by taking the diameter of the driving or rear wheel, counting the teeth on both chain wheels, and then multiplying and dividing as above.

*Necessary Tools.*—Before commencing the construction of our bicycle, some mention must be made of the tools required. The proper place to conduct such a piece of work is the mechanic's shop, whether the regular business mechanic or the amateur, as these papers are intended for both. It cannot be expected that the trained mechanic—say, a machinist—who has never made a bicycle or looked into its mechanism can know all about it without a little instruction, any more than the amateur mechanic who may have confined his efforts to the making of model engines, electric machines, and such like. The working mechanic may have to his hand most of the tools required for bicycle construction, and, having possibly more practice in their use, may make better progress with his machine than the average amateur. Unless he is what is called a gentleman amateur, his stock of tools is, as a rule, very limited, and many of them only a makeshift for the purposes they are put to. So for the benefit of the amateur with limited means I will name the tools he cannot well do without, unless he means to bother outsiders to do this and that operation for him. The indispensable tools are:—

*Lathe.*—A turning lathe, back speed, with slide rest. The back speed is for turning iron, and the quick speed for brass and wood turning. The slow speed is also used for heavy drilling, and quick speed for small drilling.

*Forge.*—A small forge for brazing and light forgings, sharpening, and tempering drills, etc.

*Anvil.*—A small anvil fixed to a bench; or, better still, a small-sized smith's anvil on a block.

*Vices.*—A large strong leg vice attached to a substantial vice board, bolted through the wall for firmness. A good parallel bench vice, 3 in. or $3\frac{1}{2}$ in. jaws; also one or two hand vices, different sizes.

*Grindstone.*—A grindstone, not less than 14 or 15 in., in a metal trough, is a most useful tool for setting up turning tools, drills, etc.

*Screwing Tackle.*—As to this, I use two die stocks, one having pairs of dies $\frac{3}{4}$ in. fine thread, $\frac{3}{4}$ in. and $\frac{5}{8}$ in. Whitworth thread; the other having dies, Whitworth standard, $\frac{1}{2}$ in., descending by $\frac{1}{16}$ in. to $\frac{1}{4}$ in.; and these I find serve nearly every purpose in the trade. For nipple screwing I use a small die stock, with five pairs of dies from $\frac{1}{8}$ in., rising by $\frac{1}{32}$ in. to $\frac{1}{4}$ in. Then for spokes I use the ordinary small size five-hole screw plate, and the one-hole plate supplied by makers and dealers, usually with two taps, for each size of spoke. Common spokes, not butted, have heads on them when bought, and consequently no spoke heading machine is needed; but butted spokes have the butt larger than the holes in the rim, consequently they must be passed through the rim from the inside before a head is riveted on. For this purpose a heading machine is used: it is a ponderous affair, costing four or five pounds, and buying it, except for makers and repairers, is out of the question. I have not one of these, but use as a substitute (a makeshift, if you like) an instrument that does the work fairly well. It consists of two steel plates which clamp the spoke, and, being held firmly in the vice, the head is hammered into shape. I will give an illustration of this instrument in its proper place.

*Ratchet Brace.* — A ratchet brace, for boring out broken spoke stumps and for many other purposes, is necessary. I use one of these with a small three-jaw cheek that holds drills from 0 in. to $\frac{3}{16}$ in. I invariably use twist drills for this tool. I use also twist drills, from $\frac{3}{4}$ in. downwards, for the various borings in the lathe.

*Smaller Tools.*—As to these, they are such as are to be found in any mechanic's kit—callipers, pliers, wire-cutting nippers, centre and other punches, an assortment of files, wrenches, spoke grips, nipple keys, and numerous other little things that suggest themselves to the tidy workman.

*Home-Made Tools.*—One of the qualifications of a mechanic is the making of many of his own tools. In this many clever mechanics are nothing short of inventors. I have several machines I never should have possessed but in this way. One of these is a small vertical driven by foot. It has a bracket and division plate, for drilling hubs from four holes to forty. I have another machine which screws spokes with three turns of a small wheel, and does the work more rapidly and more accurately than anything I know of. Another machine of my own construction is used for grinding and polishing with emery-wheels; another for bending tubes. I may have occasion in the course of these papers to describe at length some of these machines.

*Lathe Chucks, Gauges, etc.*—Of course, much work may be done without these machines: thus, hubs may be drilled in the lathe; spokes may be screwed by simply gripping them in the vice, and fixing the screw plate to the end of the ratchet brace, filing up and polishing by hand without the grinding machine. Every mechanic, however, who can possibly afford it should provide himself with a couple of chucks for his lathe—one a four independent jaw chuck, and the other a two-jaw chuck, to hold small pieces of work, such as pins, and to hold the twist drills from 0 in. up to $\frac{3}{4}$ in. or so. Either of the chucks referred to can be bought for about 55s. About the most useful article I have is the Birmingham wire gauge plate. For sizing wire, drills, pins, and other purposes, it saves a large amount of time. Stubbs' letter gauge is also used for sizing twist drills, etc., but being costly, its use may be dispensed with.

## ELECTRO-GILDING BROOCHES, CHAINS, RINGS, ETC.

BY GEORGE EDWINSON BONNEY.

INTRODUCTION — TOOLS REQUIRED — BATTERIES: DANIELL'S BATTERY, WOLLASTON'S BATTERY, SMEE'S BATTERY, GASSNER DRY BATTERY— THE VATS — THE GILDING SOLUTION — INFERIOR GILDING SOLUTION.

*Introduction.*—Jewellers in a small way of business in country towns and other out-of-the-way places, have little trinkets handed to them to be repaired and electro-gilt or electro-plated. As it is not always convenient to send these little jobs to London or to Birmingham, there may be some who will be glad to know how they may be done at home in their own workshops. There may also be a few amateur metal workers who may be glad to know how to gild or silver a few little trinkets and other knick-knacks for their lady friends and relatives. To meet the possible wants and wishes of such readers as these, I have written a short series of articles, showing how such little jobs may be done at home with a few tools, many of which can be made by the working jeweller or the amateur metal worker.

*Tools required.*—In the catalogue issued by Messrs. Canning and Co., Great Hampton Street, Birmingham, the following list is given, under the head of "Watchmakers' and Jewellers' Gilding and Silver-Plating Outfit":—Two 6 in. Daniell batteries in box, 1 lb. sulphate copper, 1 pint sulphuric acid, 1 pint gold solution, 1 porcelain gilding vessel, 1 Bunsen burner, 1 pint rich silver solution, 1 porcelain vessel, 1 pint copper solution, 1 duplicate vessel, 3 stands for holding vessels, 8 oz. cyanide potassium. The whole, packed in box, with book of instructions, for £6.

This will give some idea of the tools required; but this is not all. In addition to the articles above mentioned, there will have to be such things as brushes to clean the goods before being plated, and polish them afterwards; wires to suspend the goods in the plating solution, various cleaning solutions, and vessels to hold these; and last, but not least, a plate of each of the metals mentioned, to form an anode in each of the solutions. Therefore, although I give the above list as a sample of those submitted to the intending plater, I beg leave to prepare one myself, and give a detailed account of each article required.

*Battery.*—As we shall electro-deposit a coat of silver on a piece of metal from a solution of silver, we must have a generator of electricity—that is, something in which the electricity can be made as wanted for the work. The cheapest and most simple method of doing this, for the purpose now under consideration, is to make up an electric battery, or a voltaic generator of electricity. There are quite a host of different electric batteries in the market, but there are only a few suitable to this work. Daniell's battery is mentioned in the above list. This is made up of a stoneware pot in which stands a cylinder or a plate of copper, and a pot of porous earthenware inside this, containing either a bolt or a plate of zinc. The outer containing pot is charged with a saturated solution of copper sulphate, and some crystals of this are suspended in the pot to keep the solution in a saturated condition. The porous pot is charged with water made acid with sulphuric acid, in the proportion of one part acid to fifteen parts of water. The zinc must be kept coated with mercury, and must not touch the sides or bottom of the porous pot. The porous pots or cells, 6 in. in height, will cost about 4d. each. The outer jars may be salt-jars, or even wide-mouthed pickle bottles. Any sheet copper, however thin, will do for the cylinder. The zinc may be also in the form of a cylindrical roll of sheet zinc, but this should be at least $\frac{1}{8}$ in. in thickness. The Daniell battery is very constant. Whilst the sulphate of copper solution is kept saturated and the zinc kept in working order, the current will not flag at all during the day; it is therefore most suitable for silver-plating and gilding, but it is very troublesome to keep in working order, unless kept well at work and employed every day. As a jeweller or an amateur may not have daily jobs to do, a troublesome battery is an inconvenience, for time can badly be spared in cleaning up the parts and getting them in working order whenever a little job comes in.

The Wollaston battery is the least costly and least troublesome, but it is also most inconstant, as its current is apt to rapidly fall off after being set to work. However, as it recovers its strength after a few minutes' rest, it is a handy battery for such short jobs as generally fall to the lot of the country jeweller. It may be made at home as follows:—Get some three or four open-mouthed jars of glass, stoneware, or porcelain, of any size from one quart to one gallon, the larger size being preferable. These jars will serve as battery cells, no porous pots being required. Next get some three or four plates of rolled zinc, just large enough and long enough to go in the selected jars. Clean the plates well in hot water containing some washing soda, then rinse them in clean water. Pour some water in an earthenware baking-dish, about enough to cover a zinc plate; then pour in carefully about one-tenth quantity of oil of vitriol. In this mixture immerse the zinc plates, one at a time, and pour on each a small quantity of quicksilver. Spread the quicksilver over both sides of each plate with a mop made of tow containing a few brass wires, and then coat them perfectly. This is termed "amalgamating the zincs." The acid mixture may be used with some more to work the battery, and the excess quicksilver can be used over again.

These zinc plates will be suspended to a cross-head of wood (each plate between two plates of copper in each cell); so we must now prepare the wood supports. These should be cut out of hard wood to the shape shown at Fig. 1, so as to enclose each zinc plate between two pieces of wood, the plates fitting in the recesses cut for them. The wood should now be well varnished, or, better still, well soaked in melted paraffin wax. Each zinc plate can then be enclosed between two wooden supports, these secured to each other by long brass screws passing through both, and the plate held up by a binding screw on the top, as shown at Fig. 2.

We must now get a pair of copper plates to each zinc plate, and these should be of the same size as the zincs, or they may be a little larger than the zinc plates with advantage. They may be of any thickness. If they can be cross-scored with a file, or have a rough coat of electrotype copper deposited on them, they will work all the better for the treatment. It will be better still if they can be coated with platinum, but this will necessitate the use of a battery and a platinum solution, which is costly. The copper plates may be secured to the cross-heads on each side of the zincs by very short brass screws, care being taken not to let any of them touch the zinc plates; or they may be clamped with brass clamps sold for the purpose, as shown at Fig. 3. This method of connecting the battery plates has the advantage over others of portability, since it is always quite easy to unclamp the plates to clean them, and reverse the zinc plates so as to wear both ends equally.

The battery jars are charged with an acid mixture, made by pouring one part by volume of sulphuric acid (oil of vitriol) into twelve parts of water, and allowing it to cool before using. The plates are suspended by the wooden cross-heads in this mixture. When it is wished to increase the pushing force of the current, the copper plates of one cell are connected by a length of No. 16 copper wire to the zinc plate of the next cell, and so on through the whole series of cells, taking in as many as may be wanted. When a low-tension current of large volume is desired, all the copper plates of the cells are connected together by one set of wires, and all the zinc plates by another set of wires. The cells may be placed in a wooden tray or in a shallow box, and all the cross-heads may be secured to a long bar of wood, which may be suspended to a support above, or to an arrangement for lifting all the plates out of the cells when the battery is not wanted. This arrangement will also be found to be most convenient for controlling the current, as its volume can be lessened at any time by exposing a less surface of the plates to the action of the battery acid. When the battery is not required for use, the plates should be lifted out of the cells, and if they are not likely to be wanted for a few days, they should be well rinsed in an abundance of water, to free them from acid. It will be necessary to take out the zinc plates occasionally, clean them, and freshly amalgamate their surfaces. This must be done at any time if the plates give off a hissing noise, and appear to be blackened by the acid.

The Smee battery is employed by small electro-platers and gilders. This battery is made up in a similar manner to that just mentioned. Platinised silver foil, soldered to copper frames, is used instead of copper plates for the negative elements, but in all other respects the battery may be made like the Wollaston just described, and will give similar results, with this exception—its action is longer sustained after being connected to the work, because it does not so soon polarise.

When a jeweller wants a battery to just do a few gilding jobs or to merely flash on a thin coat of silver to hide defects or discoloured patches, and is only likely to use the battery for a few minutes at a time during the day, I strongly recommend the Gassner dry battery. This battery needs no attention in the way of setting up or cleaning, as it is always ready for work, and will furnish current sufficient to gild a brooch, scarf pin, or even a bracelet, or to silver-plate such an article with a thin coat of silver. The large double-carbon square cells should be selected for this purpose, and the battery should be made up of two of these cells in series. They cost about 4s. 6d. each cell, and will last about two years, without renewal, on such intermittent work as I have just described. If used for big jobs, taking more than ten minutes in the doing, the battery will soon be exhausted. If the Gassner battery is selected, it will not be necessary to provide a sulphuric acid solution, since no solution of any kind will be required to work this battery.

*The Vats.*—These are the vessels to hold the depositing solutions of gold, of silver, or of copper. Gilding solutions are worked

hot, at a temperature varying between 140° and 180° Fahr.; we must therefore provide a vat that will bear being heated up to this point. "Well," the tyro might say, "why not use an iron or a tin vessel, such as a saucepan?" Because the gilding solution will eat away iron or tin, and become spoiled with these metals, and because the gold will be deposited on the sides of the vat, and thus cause a loss of this precious metal. But the homely saucepan is not to be despised, for it is a useful article, and may be easily pressed into service. If we put the gold solution into a stoneware or porcelain jar, and place this in a saucepan, together with some hot water, we may heat the solution in the saucepan by placing it over a gas stove or over a fire, or any other source of heat. If the saucepan is lined with porcelain, or vitrified, or enamelled, we may heat the solution in the saucepan without using a porcelain or a stoneware jar, and the saucepan will then serve the purpose of a vat.

The silver solution will be worked cold, so we shall not require a vessel to stand the heat as a vat for this solution; but it must not be of metal, because the cyanide of potassium in a silver solution will dissolve a metal vat, and the silver is liable to be deposited on its sides. It does not act quickly on lead; and this is sometimes used to line vats employed to hold plating solutions, but a lead-lined wooden vat would be too cumbersome for our purpose. If only a quart or two of silver solution is employed, we may find a stoneware vessel large enough to hold the solution. A large stoneware battery jar will serve the purpose very well, but either the stoneware or the glass troughs used for the cells of accumulators will make the best of vats for silvering solutions. If these cannot be easily obtained, and a bell glass can be got—that is, a glass vessel shaped like a bell, and employed by gardeners to cover their plants, and by fish fanciers as aquariums for gold fish—this can be easily improvised as a plating vat. Carve out a wooden pedestal to hold the knob of the glass, and cement this into the wood base. Do not use a common earthenware vessel, whether glazed inside and out or not, as these are snares, ever liable to be destroyed by the cyanide and to break when least expected.

The coppering solution I shall recommend can be worked cold or hot, and may therefore be held in a vat similar to that employed for the silver solution. The vats may be stood on any bench or on a shelf. They will not need any other stand, but, for the sake of cleanliness, it is advisable to place each in a lead-lined tray, to catch any accidental drops of the solution, as this will penetrate wood and leave a disagreeable odour about the shop, even after all the plating things have been put away.

*The Gilding Solution.*—After several years' experience, I find the following the cheapest and best for the amateur gilder and the jeweller in a small way of business. Get one pint of distilled water from a druggist's shop, and also half a pound of best 95 per cent. cyanide of potassium. Please understand that this latter-named article is a deadly poison, and will injure health if handled with the naked hand. There will, therefore, be some difficulty in getting it, and when got, great care must be exercised in using it, and in keeping it in a safe place when not in use. It should be kept in a wide-mouthed glass-stoppered bottle, under lock and key. Dissolve two ounces of the potassium cyanide in one pint of hot distilled water, and place it in the vessel intended to serve for a vat. Get two strips or plates of pure gold, weighing from 7 to 10 dwts. each; punch a small hole in the upper edge of each, and hang each strip on a hook made of No. 20 platinum wire. Hang one strip in the vat connected to the wire leading from one pole of the battery (say, the zinc plate), and the other strip of gold to the wire leading from the other pole of the battery. See that the gold only

Fig. 1.—One-half of Wood Support for Battery Plates.

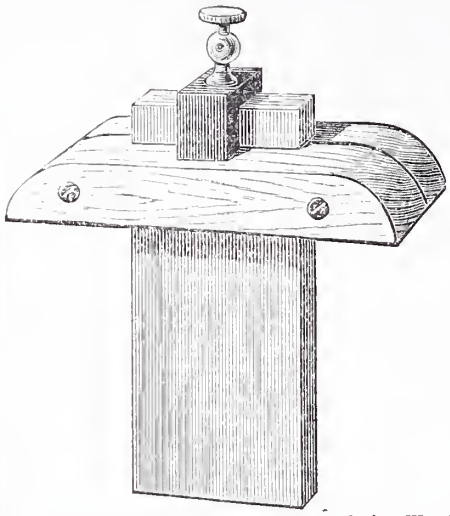

Fig. 2.—Zinc Plate of Battery held in Wood Support.

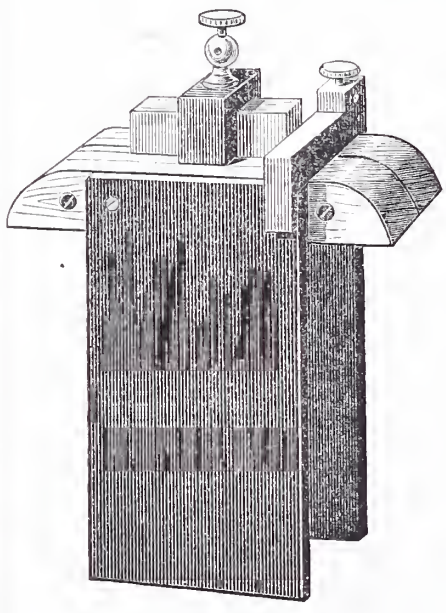

Fig. 3.—Battery Plates mounted on Wood Support and clamped together, ready for use in Cell.

dips deep enough in the cyanide solution to just touch the platinum hooks, but do not allow the copper wires to hang in the solution. Copper and gold will dissolve in cyanide solutions, but platinum will not dissolve in them. We want to dissolve the gold, and so make up a gilding solution, but we do not want any copper in the solution, as this will make the gold of a dark colour. If all has been done right, an electric current will pass from the zinc plates in the battery to the copper plates, and from these along the wire to the gold strip in the cyanide solution, through this, and back to the battery by way of the other gold strip and the wire leading to the zinc plate, thus completing the electrical circuit. Whilst current is passing in this way, gold will be dissolved off from the strip of gold hanging to the wire leading from the copper of the battery, and will be taken up by the cyanide of potassium to form the double cyanide of gold and potassium solution. Keep the solution heated up to 160° Fahr., and keep the battery connected to it for one or two hours. At the end of this time hang a German silver wire for a moment or two in the vat, connected to the wire leading from the zinc of the battery. If the wire takes on a coat of a satisfactory character, hang both strips of gold to the opposite wire, and call them gold anodes, and connect the work to be gilded to the cathode wire—that is, the wire from the zinc of the battery. The action of the battery may be carried on until 5 dwts. of gold have been dissolved into the solution, or we may commence gilding with only 1 dwt. of gold to the pint of solution. The quantity of gold in the solution can always be augmented if the surface of the things to be gilded is less than the surface of the anodes, and there is an excess of cyanide in the solution. The contrary condition will result, of course, in an impoverishment of the solution. A solution rich in gold deposits a rich-looking coat of gold in a short time, whilst one poor in gold works slowly, and deposits a poor-looking coat.

A full battery of at least three Wollaston, Smee, or Daniell cells, or two Bunsen cells, should be used in making the gilding solution, but it can be worked afterwards with a battery of one cell. The Gassner or the Leclanché are both unsuitable to use in making up the solution, but may be used in working it after it has been made up.

An inferior gilding solution may be made up by stirring into the cyanide solution enough chloride of gold to turn the solution green, then adding enough cyanide to take away the green tint. This will deposit a coat of gold of a fairly good colour, but the gold coat is apt to strip off whilst being polished or burnished. The best depositing solution is that of the double cyanide of gold and potassium made up by the chemical method, but the process for doing this requires more than an amateur's skill, and results in a great loss of gold when attempted by unskilled persons.

In another paper I hope to show how to prepare the articles for gilding, to work the gilding solution, and finish the goods after they have been gilded.

## AN EASILY-MADE RECEPTACLE FOR PARTS OR NUMBERS OF "WORK."

BY A. BEAN.

"Alas! things are not as they seem." This trite quotation has been so often used to express disappointment and disgust at expensive purchases which had been regarded as valuable in an equal degree, until suddenly discovered to be just the reverse, that it is quite a pleasure to be able to employ it (without its dispiriting prefix) in connection with a perfectly honest article.

As such we may fairly consider, I think, the book about to be described, and which is shown in the annexed illustration. This sketch, as the reader will no doubt observe, portrays apparently a neatly bound copy of

WORK; but the uninitiated searcher who may peer under its cover in natural expectation of help, in place of receiving any useful assistance from this volume, will find that the so-called book has resolved itself into a mere box; which, however, in its very singularity, may, let us hope, compensate somewhat for the absence of the anticipated assistance.

To its would-be maker, at any rate, this book-box will offer many inducements apart from that of novelty. For one thing, it is decidedly most useful for a variety of purposes. It is, moreover, easier by far to construct than the binding of a volume of printed sheets; which may, indeed, be so spoiled either by the sewing or the cutting of the edges as to be beyond the power of anyone, professional or amateur, to repair. Indeed, the greatest incentive of all, to one who has ever endeavoured to satisfactorily smooth the edges of books by the ordinary methods of the amateur, will be, I think, the fact that here, at all events, he will be spared that trial.

To those readers who do not possess the bookbinder's usually most used appliance, it will doubtless be an additional relief to learn that for our present purpose a press is quite unnecessary; the only tools required being a knife (known to dealers in cutlery as a French one), a folding stick or thick bone paper-knife, a glue-pot, and a brush.

Any ordinary binding material may be used in covering this box, but I should recommend, as being the most suitable, the leather denominated roan (which may be had of any colour) as protection for the back and the corners, bookbinder's cloth of a similar shade being placed on the sides. For lining the interior of the box, paper of a drab or grey shade is to be preferred, whilst the seeming edges should be covered with marble paper.

The boards needed will be one No. 3, and two No. 6 black ones, the former measuring 18 in. by 16 in., and the latter $12\frac{1}{2}$ in. by $9\frac{1}{4}$ in. each. About a quarter of a yard only of cloth will be necessary, whilst the piece of leather should measure $20\frac{1}{2}$ in. by 6 in. You will need no more than a sheet each of the lining and marbled papers.

Having obtained these essentials from any bookbinder, you may cover the thinner millboard on one side with the drab paper and cut it to the shape shown in Fig. 2. It should then be scored or cut half through its thickness with a sharp knife along the dotted lines on the uncovered side.

This will enable you to bend up the outstanding portions without cracking the board, after which, in order to secure them in place, you should glue strips of cloth along each angle on the outside of the box. About $\frac{1}{4}$ in. of each of these four pieces should be turned in over the upper edges, whilst their lower ends to the extent of half an inch should be attached to the foundation. One side of the board you will of course have arranged to fit the curve of the two end-pieces, so that a properly shaped back may be formed. The finishing touch to this portion of the volume is given by affixing a strip, 32 in. by $3\frac{1}{2}$ in., of marble paper around the three straight sides.

I may here perhaps be allowed to mention a difficulty with which you will doubtless have noticed I have to contend in describing this book as a box, and *vice versâ*. For you must not forget that the *sides* of the box form the edges of the book, whilst the two sides of the latter are spoken of as top and bottom respectively in the case of the former.

However, we may now leave the box proper for the present, and turn to the consideration of its surroundings. For these you must cut the piece of leather as shown by the lines in Fig. 3, the portion A being required for the back, and the offcuts B for the corners; the remaining small square may be regarded as useless save for the purposes of experiment.

Now make your knife as sharp as possible, and employ it in cutting or paring down the edges of the five pieces of roan, using a slab of glass or porcelain to support the leather against the pressure of the blade. The four similar portions should then be

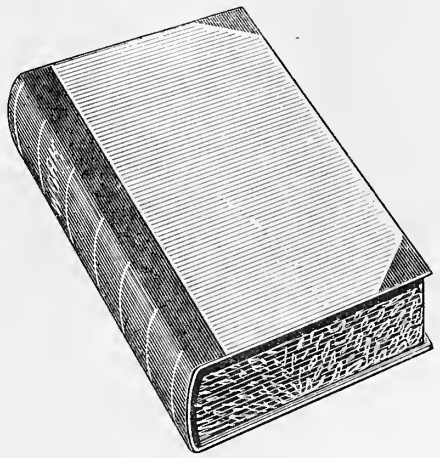

Fig. 1.—Book-Box as Receptacle for Parts or Numbers of "Work."

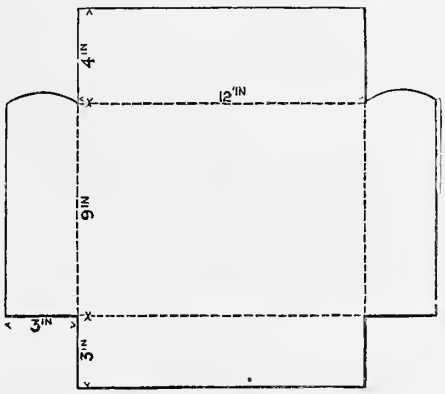

Fig. 2.—Plan of Pasteboard for Body of Box.

Fig. 3.—Mode of cutting Leather for Back and Corners of Case.

parted and placed on two corners of each board, their oblique edges being turned over their borders. After pasting the larger piece thoroughly over, lay at a distance of $1\frac{1}{2}$ in. from each of the longer edges the uncornered margin of one of the boards. A short piece of thick cord should then be placed across each end of the leather, reaching from corner to corner of the boards, in order to strengthen the roan somewhat; the overhanging portions being then turned tightly over in the same style as the smaller pieces.

Two pieces of cloth, each 14 in. by 9 in., should now be cut, and after just so much of their corners has been removed as will allow their leather substitutes to fully appear, affixed to the boards with thin glue, their extreme edges being turned in as before.

The inner and outer divisions of the volume will now be quite ready for amalgamation. This must be done by attaching the rounded *side* of the box to the leather back of the case with rather thick glue. After well rubbing these two together with the folding stick, you may then fasten the bottom of the box to the corresponding side of the cover.

To give finish to the upper portion of the receptacle, a strip of cloth 1 in. wide and 12 in. long should now be neatly glued along the inner joint of the board—or lid if you choose—where fastened to the curved side of the box, a piece of marble paper 12 in. by $8\frac{3}{4}$ in. being then evenly applied to the inside of that upper cover.

A box, however it may be enclosed, is scarcely a fit subject on which a 'prentice hand may successfully practice gold lettering; therefore, if you have not already had some experience in that branch, I should advise you to either employ the painter's method, or give instructions to the binder for its embellishment.

If the former plan is adopted, the back must first be divided into seven portions or panels, the five inner ones being made quite equal whilst the upper one should be about $\frac{1}{4}$ in. longer, and the lowermost one only half that length. A line of, say, $\frac{1}{16}$ in. should then be drawn between each of these divisions with a fine brush charged with gold size, additional ones being also placed parallel to the head and tail of the back, and also against the verge of the sides of cloth.

These lines must be left until they are very nearly dry, when you may lay over them the gold leaf or bronze powder in the same manner you have no doubt often observed painters adopt when using these materials.

If you succeed in doing this portion satisfactorily, you may then write the word WORK or other title with the same liquid on the second panel of the back, afterwards attaching the gold as before.

This plan, although perhaps somewhat of an innovation, will nevertheless give the book quite a legitimate appearance; and will look as well, if not better than many far more elaborate attempts with the ordinary tools of a book-finisher.

## PROMISCUOUS EXERCISES IN CHEMICAL ANALYSIS.

BY "CHEMICUS."

As examples, let us take "The detection and estimation of lead in potable waters," "The analysis of solder," "The determination of *added* water in milk," "The analysis of white lead," and "The estimation of moisture, ash, and sulphur in coal."

### DETECTION AND ESTIMATION OF LEAD IN POTABLE WATERS.

The presence of lead in potable waters may be readily detected by adding two cubic centimetres of a saturated, freshly prepared solution of sulphuretted hydrogen to fifty cubic centimetres of the water, acidified with ten drops of acetic acid, contained in a Nessler's cylinder. Should the water hold solid matter in suspension, or be turbid, it is filtered previous to applying the test. This applies also to the bichromate method of detection described hereunder. If the metal be present the

water upon standing some little time will acquire a brown colour, varying in depth of tint in proportion to the amount contained in the sample. For comparison, fifty cubic centimetres of lead free water, contained in a Nessler's cylinder, are treated in a precisely similar manner. Should the fifty cubic centimetres yield negative results, half a litre of the water is taken, the volume reduced by evaporation to fifty cubic centimetres, filtered if necessary, cooled, and the above test applied. If this portion also gives negative results, the water is free from lead.

It is claimed by the author, Mr. Sidney Harvey, that the presence of one-fiftieth of a grain of lead per gallon may be readily detected by the method described hereafter. And further, that no other metal likely to be contained in the water gives the same reaction with the reagent employed—viz., bichromate of potash. The principle of the method is, that lead salts form with bichromate of potash insoluble precipitates of chromate of lead.

In applying the test, 0·13 grammes of powdered bichromate of potash is added to half a litre of the water contained in a glass conical, the liquid well stirred and allowed to stand at rest, alongside, for comparison, of a similar conical containing half a litre of lead free water, to which the same quantity of bichromate of potash has been added. During the course of fifteen to twenty minutes a decided turbidity will be formed, should lead be present, while at the expiration of about twenty-four hours a precipitate will have settled at the bottom of the containing vessel, so that the supernatant liquid can be drained off almost to the last drop.

Lead being a very serious contamination of potable waters, since, when taken into the system, it accumulates and does not pass through, we give the following simple method for its detection, so that those of our readers who do not possess a knowledge of chemistry—and undoubtedly they are many—may determine for themselves whether this injurious and poisonous metal be present or not in their water supply. For the carrying out of the process, the apparatus required consists of an ordinary glass tumbler, and two bright and perfectly clean knitting needles; while the only chemical employed is acetic acid, or, if this is not at hand or procurable, vinegar. The *modus operandi* of the method is as follows: Fill the tumbler at least three parts full with the water to be examined, and add a dozen drops of acetic acid, or a teaspoonful of vinegar. Should the water be turbid, treble these quantities are added. Thoroughly mix the contents of the tumbler by carefully stirring with the needles, immerse the needles in the water, and allow them thus to remain in contact with the water, with occasional stirring, for some considerable time. From time to time withdraw one of the needles, always the same one, and examine its surface for dark or brown spots; or if the amount of lead is considerable, a grey coating, varying in depth of colour in proportion to the quantity present, which will be formed should lead be contained in the water. If, after immersion in the water for some eight to ten hours, the needles remain free from any spots or coating, even when examined with the aid of a magnifying glass, as will be the case when only small quantities of lead are present, withdraw the needles and allow to dry, precautions being taken to exclude dust, for twenty-four hours. If at the end of this time the needles have acquired no yellow, or reddish-yellow colour, the water is free from lead.

For the *quantitative determination* of the lead, fifty cubic centimetres of the water are carefully measured out into a Nessler's cylinder, four drops of acetic acid, together with two cubic centimetres of a saturated, freshly prepared solution of sulphuretted hydrogen, added, and the whole mixed. The colour of this solution is now compared with that of fifty cubic centimetres of pure distilled water, contained in a Nessler's cylinder, to which four drops of acetic acid, and two cubic centimetres of the sulphuretted hydrogen, as also one cubic centimetre of a standard solution of lead containing in every cubic centimetre ·0001 grammes of lead, have been added. To compare the colours of the two solutions, place the containing vessels side by side on a sheet of white unglazed paper, or a porcelain slab, and look down through them.

Should the colours of the two liquids differ, various quantities, larger or smaller as required, of the standard lead solution are added to fresh portions of fifty cubic centimetres of pure water, acetic acid and sulphuretted hydrogen added as before, until the quantity of the standard lead solution necessary to produce equality of tints in the two solutions is arrived at. Since each cubic centimetre of the standard lead solution contains ·0001 gramme of lead, the quantity of lead, in grammes, contained in fifty cubic centimetres of the water under examination will equal the number of cubic centimetres of the standard solution required to produce equality of tints multiplied by ·0001, and therefore a litre (1,000 cubic centimetres) will equal this quantity multiplied by 20. By multiplying grammes per litre by 70 we obtain *grains per gallon*.

Example:—50 cubic centimetres of the water taken for analysis. Number of cubic centimetres of standard lead solution required to produce equality of tints=6 cubic centimetres.

∴ 50 cubic centimetres of the water contains ·0001 × 6 = ·0006 grammes of lead.

∴ 1,000 cubic centimetres (a litre) of the water contains ·0006 × 20 = ·012 grammes of lead.

∴ *Grains* of lead *per gallon* of water = ·012 × 70 = ·84 *grains* of lead per gallon.

If the qualitative analysis has revealed the presence of only a small quantity of lead, a litre of the water is evaporated down to a volume measuring fifty cubic centimetres, filtered if necessary, cooled, and the lead determined as above.

The standard solution of lead is prepared by dissolving ·1831 grammes of crystallised acetate of lead in a litre of distilled water.

### SOLDER.

For the analysis the sample is cut up into small pieces, the smaller the better.

Weigh out into a conical one gramme of the solder, add fifty cubic centimetres of a mixture of equal parts strong nitric acid and water, and heat gently. When solution is effected, add 250 cubic centimetres of dilute nitric acid—one acid to six water—and carefully evaporate the solution down until it becomes pasty. When cool add 250 cubic centimetres of the dilute nitric acid, boil until the volume is considerably reduced, dilute the liquid with water, and allow to stand until the resulting metastannic acid has completely subsided to the bottom of the containing vessel. Collect the precipitate on a double Swedish filter, and wash until free from acid. Dry the filter paper with contents, remove the dry precipitate as completely as possible to a tared crucible, ignite the filter paper separately, add the ash to contents of crucible, ignite the whole at a strong red heat, and when cool re-weigh to determine the oxide of tin, $SnO_2$, which contains 78·67 per cent. of metallic tin.

Concentrate the filtrate remaining from the determination of the tin if the volume occupied is at all considerable, cool, add pure sulphuric acid in slight excess, and then twice the volume occupied by the solution of methylated spirits. Allow the solution to stand for some considerable time, collect the resulting precipitate of lead sulphate, $PbSO_4$, on a filter, wash with water acidulated with sulphuric acid, and subsequently with methylated spirits. Dry filter paper with contents, remove the dry precipitate to a tared crucible, and ignite the filter paper in the manner described in the article on "Brass: Its Analysis" (Vol. II., page [367). Add the filter paper, ash, etc., to the contents of the crucible, ignite the whole, and weigh the $PbSO_4$, which contains 68·32 per cent. of lead.

### DETERMINATION OF THE "ADDED" WATER IN MILK.

To arrive at the extent to which milk has been adulterated by the addition of water, it is necessary to make a determination of the "Solids not Fats," which is conducted as follows:—Carefully tare a perfectly clean platinum dish and in it place about ten cubic centimetres of the milk. Re-weigh the dish to determine the exact weight of the milk taken, and then submit to the action of the water-oven until evaporation to complete dryness has taken place. This beng effected, the dish and contents are allowed to cool, the dry residue covered with 100 cubic centimetres of benzoline, and heated in the water-oven until one-half of the benzoline has evaporated off, when the dish is withdrawn, allowed to stand until the solid particles have completely settled to the bottom, and the liquid then carefully decanted off. Repeat this treatment with benzoline some half dozen times, and after the final treatment, decant off as completely as possible the liquid, dry the residue in the water-oven for an hour, allow to cool, and weigh. Replace in the oven, heat for a further period of half an hour, and again weigh. If the second weight does not agree with the first, the dish and contents are again subjected to the action of the water-oven until a constant weight is obtained. The residue thus obtained is the *solids not fats* contained in the weight of the sample operated upon; it is calculated on100 parts by weight. In genuine milk the percentage of *solids not fats* is 9 per cent., and should it be under, the sample may be considered as watered.

The percentage of *added water* in milk is the difference between amount of pure milk in which percentage amount of *solids not fats* found are contained, and 100.

To determine the amount of *pure milk* in which the amount of *solids not fats found* is contained, it is assumed that 9 *parts of solids not fats* are contained in every 100 *parts* of *genuine milk*. Example:—

A sample of milk upon analysis is found to contain 8·00 per cent. of *solids not fats*. If, therefore, 9 per cent. of *solids not fats* are contained in 100 *parts of genuine milk*, 8 *per cent. of solids not fats* are contained in 8—100 ÷ 9 = 88·88 *parts of genuine milk*.

The amount of *added water* is, therefore, 100—88·88=11·12 per cent.

### White Lead.

The chief adulterations of the white lead of commerce are barium sulphate, calcium carbonate (chalk), and oxide of zinc. Barium sulphate, however, cannot be considered an adulteration unless it be present in quantities exceeding 5 per cent., since it serves to protect the lead from the blackening action of sulphuretted hydrogen.

The following is the method of analysis :—Weigh out one gramme of the sample, spread in a thin layer over the bottom of a small porcelain dish, and burn off the oil at a low temperature, continuing the ignition until no black carbonaceous matter remains. Cover the residue while hot with dilute nitric acid, digest at a gentle heat, dilute the solution and filter. Wash the insoluble residue on the filter free from acid, dry, ignite and weigh.

The residue thus obtained should be qualitatively tested for barium sulphate in the following manner:—Place a small portion of the residue on the end of a platinum wire, moisten with hydrochloric acid, and hold in the flame of the blowpipe, when if barium be present the flame will acquire a green colour. If no coloration be produced, the residue consists of silicates. It is not usual to separate the barium sulphate and silicates should both be present.

The filtrate remaining from the above determination is evaporated to near dryness to expel the excess of acid, diluted, heated to near boiling, and a current of sulphuretted hydrogen conducted through to saturation. (The solution must be distinctly acid, otherwise zinc sulphide will be precipitated.) The liquid is then allowed to stand at rest for some time, and the resulting precipitate of sulphide of lead collected on a filter and washed with sulphuretted hydrogen water. The filter paper with contents is then placed in a tared porcelain crucible, covered with strong nitric acid, gently heated until the acid is driven off, when the temperature is increased to redness, and the crucible, after cooling, re-weighed to determine the lead sulphate, $PbSO_4$. Every 100 parts of lead sulphate is equivalent to 88·118 parts of lead carbonate, $PbCO_3$.

To the filtrate from the sulphide of lead, add ammonia and ammonium sulphide in excess, close the mouth of the containing vessel, and allow to stand at rest in a warm place for some hours. Collect the resulting precipitate of sulphide of zinc on a Swedish filter, wash, dissolve in hot dilute hydrochloric acid, dilute the resulting solution, heat to boiling, and re-precipitate the zinc in the same, as carbonate, by the addition of sodium carbonate in excess. Heat to boiling, filter off the carbonate of zinc, $ZnCO_3$, wash thoroughly with hot water, ignite in a porcelain crucible, and weigh the resulting oxide of zinc, ZnO.

The ammonium sulphide filtrate remaining from the above determination, after the addition of hydrochloric acid, is evaporated to dryness, the residue brought into solution by digestion with dilute hydrochloric acid and filtered if necessary. The solution is then made strongly ammoniacal, ammonium oxalate—prepared by dissolving one part of the crystals in ten of water—added and heated to boiling for some time. The resulting precipitate of calcium oxalate collected on a Swedish filter, washed with water, converted into lime, CaO, by ignition at a strong heat, and weighed as such. Every 100 parts of CaO is equivalent to 242·857 of $CaSO_4$.

As regards the arrangements of the results, the residue insoluble in nitric acid is returned as *barium sulphate and silicates;* the lead as *lead carbonate;* the zinc as *zinc oxide;* and the lime as *calcium sulphate.*

### The Determination of Moisture, Ash, and Sulphur in Coal.

*Moisture.* — Carefully weigh out five grammes of the coal, which has been reduced to a fine powder, spread in a thin layer over the bottom of an iron dish or the surface of a clock glass, and submit to the action of the water-oven for an hour. At the expiration of this period, re-weigh the coal to determine the loss in weight which it has suffered, which loss represents the *moisture* on the quantity taken for analysis.

The portion thus deprived of moisture is preserved in a well-stoppered bottle, from which the various portions required for determination of ash and sulphur are taken.

*Ash.*—Weigh out into a large, shallow, tared platinum, or porcelain dish, one gramme of the moisture freed sample and gently ignite, with a free excess of air, over a Bunsen burner until the volatile matter is expelled and the coal is thoroughly coked. When this is effected, increase the heat to bright redness, and maintain at this temperature until the residual ash is free from black carbonaceous matter. This being attained, allow to cool, and re-weigh the crucible to determine the ash.

To ascertain whether combustion is complete, ignite the crucible with contents for a further period of ten minutes, allow to cool and re-weigh. The second weight should agree, within experimental error, with the first; if it does not the ignition is repeated until a constant weight is obtained.

*Sulphur.*—Intimately mix one gramme of the dry powdered coal with twice its weight of pure calcium oxide (lime), place the mixture in a platinum crucible and gently ignite over a *spirit lamp,* or, as is preferable, in the muffle, for half an hour. When this period has expired, increase the heat to bright redness and maintain at this temperature for about an hour, upon the expiration of which time remove the crucible from the source of heat and allow to cool. Cover the contents of the crucible with a small quantity of a saturated solution of ammonium nitrate, and apply a gentle heat until the liquid is driven off. By thus treating with ammonium nitrate, the calcium sulphide, formed by the combination of the sulphur of the coal with the calcium of the lime, is oxidised into calcium sulphate. Oxidation having been effected, place the crucible, when cool, in a beaker, cover with pure hydrochloric acid, and digest at a gentle heat until the mass has dissolved out. Withdraw the crucible after washing, dilute the solution, filter through a Swedish filter paper and wash. Dilute the filtrate, which now contains as sulphuric acid the whole of the sulphur present in the coal, to 250 cubic centimetres (the solution must be distinctly acid, but free from a large excess), add ten cubic centimetres of barium chloride solution, and allow to stand in a moderately warm place for twelve hours. Decant off as much as possible of the clear supernatant liquid, collect the resulting precipitate of barium sulphate on a Swedish filter, wash twice with dilute hydrochloric acid and thoroughly with water, ignite and weigh. Barium sulphate, $BaSO_4$, contains 13·37 per cent. of sulphur.

It is advisable to form a blank experiment with the re-agents employed, taking the actual quantities of each as employed in the analysis of the coal.

## DESIGN FOR GLOVE BOX IN FRETWORK.

BY ROBERT COXON.

### Subject of Design : "Music."

This design, if executed in a good hard wood, vulcanite, or brass, either as fretwork on another ground or in inlay, would make a very artistic article, either for gloves for a lady or any other articles for which it might be used.

The drawings are worked out full size, the top (Fig. 1) and end view (Fig. 2) complete, the side view (Fig. 3) repeating from centre, *c c.* The accompanying small sketch

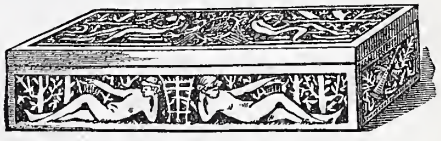

**Fig. 4.—Sketch of Glove Box complete.**

(Fig. 4) will serve to show the work complete, and could be either hinged or as a lid at the option of the workman. Figs. 1, 2, 3 will be found in page 41.

Having designed it to suit brass inlay work, for which it is more suited in the delicate portions, the workman must slightly thicken those parts if intended for wood execution.

It would also make a good subject for a music stand, either for a piano front, table stand, or upright, the top piece forming centre, with the side view repeated top and bottom, and mounted on coloured satin, silk, or velvet.

For the box, also, coloured material might be used as lining, or, if preferred, gilt cardboard mount or thin sheet brass would make a more suitable background to a dark wood like ebony or vulcanite, the inside being mounted in plush or velvet.

## FURNITURE AND ITS GLASS.

BY DAVID DENNING.

Glass as a Decorative Feature—Plate Glass — Silvering — Preparation of Frame — Measurement of Glass and Bevels—Purchasing Glass.

After wood, there is no material which forms such an important part in cabinet furniture as glass. Of course, the appearance is referred to more than the actual construction when it is said that glass is so important a feature; for glue, nails, and other odds and ends are, so far as joinery is concerned, of infinitely greater use than glass. They, however, are not supposed to be visible, and in good work are not more so than is absolutely unavoidable. Glass, on the contrary, is introduced into furniture almost entirely owing to the decorative effect which it gives when judiciously used. There are, of course, those who object to the use of glass in furniture except to the smallest extent, and from their point of view the reasons they give for doing so are not trivial. It is, however, not so much my intention to discuss the use of glass from an artistic basis as to offer a few hints of a practical kind to those who will have glass in their rooms. As one who has paid some attention to the subject, perhaps I may be allowed to make a few remarks about the general employment of glass. So far as I can understand the objections to its use, they are mainly because glass is seldom found in old furniture, and then only in

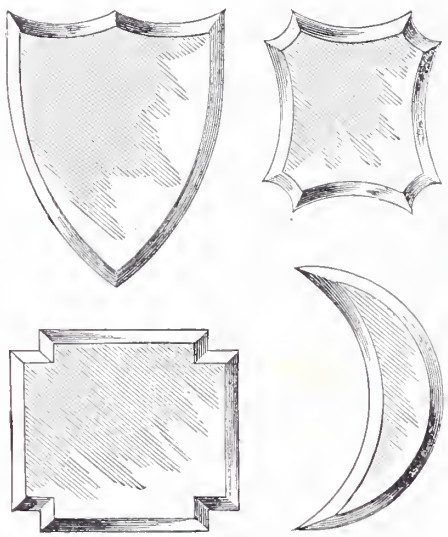
small pieces. It was never employed in large sheets; therefore, to do so now is an evidence of want of good taste, as the glitter is apt to destroy the repose which should characterise the interior of our dwellings. That is what has been said by the "utterly too too" artistic section of the community. Now, let us just look at the subject from a popular or common-sense point of view.

It is quite true that till a comparatively recent period glass was not used in large pieces in furniture, but its absence is not to be taken in any way as a proof of its use having been purposely avoided. Probably the real reason is to be found in the fact that glass has not always been obtainable in large sheets or plates. What is not made cannot be used, so that large mirrors never being found in old furniture merely shows that the old cabinet-makers had not got it to use. It is nothing but nonsense to urge that their superior artistic instinct induced them to use glass in great moderation, and only in small pieces. Whether or not glass is ornamental in furniture is to a great extent a matter of personal opinion on which everyone has the right to decide for himself—unless, indeed, he has a better half, for then he may possibly find his rights restricted. Those who do not like glass may have wood or some other material instead, while those who wish for plenty of it can have their wishes gratified to almost any extent without being thought peculiar or addicted to vulgar decoration. At the same time, it must not be understood that I am advising the excessive use of glass, for, personally, I am decidedly of opinion that it should be employed judiciously and in moderation—or, rather, I should say, with discretion.

The advantages of glass as a decorative material in furniture construction are so manifest that it may seem almost unnecessary to say anything about them. It must suffice just to remind decorators that they have a most useful material to deal with, and that they can combine utility with ornament. After all, if everything that might be said both for and against glass as a decorative part of furniture were to be urged, it merely resolves itself into this—glass is fashionable and popular. We find it largely used in overmantels, sideboards, cabinets, and all kinds of fancy furniture, principally in a silvered state—*i.e.*, as looking-glass or mirror. In furniture, transparent glass is comparatively little used, and when it is its object is principally to allow of the contents of the cupboard, or whatever it may be, to be seen. An ordinary bookcase with glazed doors will occur to most people as a familiar example.

Undoubtedly, a great stimulus to the use of glass as a purely decorative detail of furniture has been given by the greatly decreased cost of bevelling the edges. As is well known, the bevelled edges to all mirrors greatly improve their appearance, and when the small extra cost is taken into account it seems hardly worth while to economise by having plain edges. As so many amateurs wish to do everything for themselves—and doubtless it is a creditable wish—this may be an opportune place to say that neither glass bevelling nor glass silvering are suitable occupations for them. On a small scale they cannot be practised successfully. It will be found much more economical to get the glass ready silvered and bevelled from a dealer. With proper plant and appliances, both bevelling and silvering can be done at a very reasonable figure. I mention these matters, as several inquirers have desired to be informed in the "Shop" columns how they can do silvering. When they know, any efforts they may make are almost sure to end in disappointment. Of course, I do not wish to discourage any, but it is better for them to know that the "game is not worth the candle" in the opinion of those who are best able to judge.

No doubt most readers are aware that the kind of glass ordinarily used for mirror purposes is known as "plate." It is more suitable than the commoner and cheaper sheet glass, from the fact of its having a more even surface, and other good qualifications. It is also fairly thick, so that the edges can be suitably bevelled. Another kind of glass, the thin or "patent plate," is only used when the ordinary kind is too thick for the purpose. For bookcase doors and transparent panels both plate and sheet glass are used. For ordinary furniture the latter is quite suitable, and is much cheaper than the former, which is, however, preferable when first-class quality is necessary. The silvering is now generally done by what is known as the "patent process," to distinguish it from the older one, in which mercury and tinfoil were used. In the patent process pure silver is chemically deposited on the glass.



Fancy Shapes for Glass Bevelling.

Having said enough about the actual material, it will be well after this preliminary chat to say something about the work of fitting and fixing the glass into the furniture—taking up the subject, in fact, from a practical or workshop point of view, so far as it concerns the cabinet-maker. Of course, it goes without saying that the more he knows about the material the better for himself, but this knowledge is not so necessary to him as an acquaintance with the ordinary workshop methods of actually using the glass, and combining it with wood in constructing furniture.

It may seem almost unnecessary to say that the edges of glass used in furniture are laid within a rabbet, but a few remarks about the rabbet itself are not uncalled for. Perhaps the chief point that the maker of any frame which it is intended to fit glass to should attend to is the absolute necessity of having it "out of winding." If it is "in winding," it stands to reason that a perfectly flat, even sheet of glass cannot be close to the wood which should support it. The consequence is, that as a space between the wood and the surface is unsightly, the workman may be tempted to try and force the glass into its proper position—*i.e.*, so far as appearance is concerned—for the proper position is naturally that in which the glass lies close, without any coaxing or straining. It may, when speaking of glass, seem strange to those who are not accustomed to working it to refer to its being forced to lie against a frame in which it does not bed naturally.

Glass is usually regarded as so absolutely rigid that any attempt to cause it to bend would be useless. Now, although for ordinary purposes glass may be considered inflexible, it is not perfectly unyielding, but any curve that may be imparted to it in order to get it to lie close against an imperfect frame is got at the risk of fracture, not only at the time, but even afterwards, especially if it is moved. It will easily be understood that the larger the glass the more readily it can be forced to fit a faulty frame; but the fact that the larger the glass the greater will be the cost of replacing it in the event of a fracture should not be overlooked. It will be found better not to try and adapt glass to a frame, but to make the frame as it should be for the reception of the glass.

From what has been said, it does not require great perceptive faculties to understand that the flat, or portion of the rabbet on which the glass lies, must be on the same level all round. In other words, the rabbet on each of the sides of the framing must be cut to exactly the same depth. To make the matter perfectly clear, let us suppose that on three sides of a rectangular frame the rabbet has been cut to a depth of $\frac{3}{4}$ in., while on the remaining one it is $\frac{1}{4}$ in. deeper. It is evident that a piece of glass of proper size being let into the frame will lie on the wood of the sides first mentioned without touching the fourth, as it would have done had all four been properly prepared to the same depth. But it may be said that such a discrepancy as that just named could not occur in practice; and this I am ready to admit, for the measurements have been purposely exaggerated in order that there may be no possibility of a mistake in even the greatest novice understanding what is meant. Although a difference of $\frac{1}{4}$ in. has been mentioned, one of even half that might be equally prejudicial. As a further exemplification of the same principle of faulty work, let us assume that instead of the whole of the rabbet of one side of the frame having been cut wrongly, it is only irregular in depth at one part—for example, that at the angle one of the pieces is not quite on the same level as the other—and it will be evident that in this case also the glass cannot bed properly. This defect is in practice much more likely to occur than the other. The remedy, of course, is to pare away with the chisel the superfluous wood, but it will be much better to avoid the necessity for doing this by taking proper precautions to have the work right in the first place. It only needs a reasonable amount of care and skill to do so. In the event of one or more sides of the frame having rabbets too deeply cut, it may be better to level them up by gluing veneer instead of cutting down the side or sides which are too high. The necessity of cleaning away any glue which may have exuded at the mitres, and become hard, must also be insisted on, for nothing is more apt to cause the glass to be fractured, perhaps because a careless worker might not notice its presence till the mischief has been done. Hardened drops of glue which have accidentally got within the rabbet must also be carefully removed. Their presence can

(*Continued on page* 42.)

Subject of Design: "Music."

Fig. 2.—Half of Front of Glove Box: reverse at line *c c* to complete.

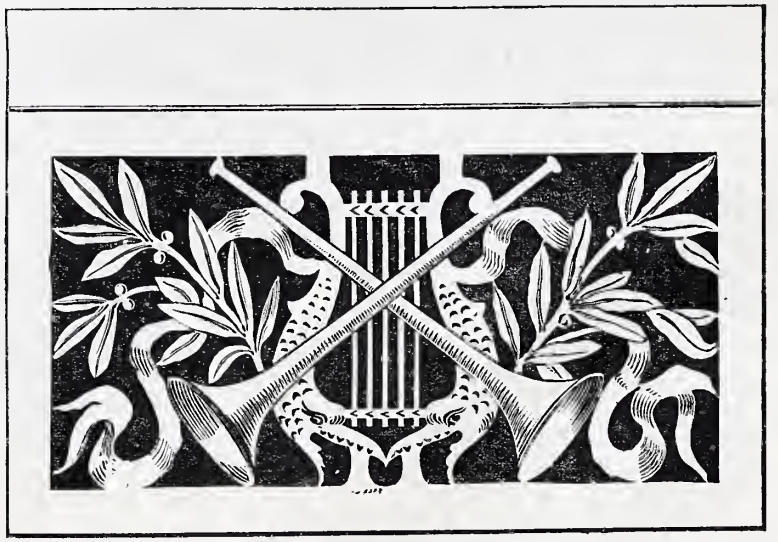

Fig. 3.—End or Side of Glove Box.

easily be ascertained by running the edge of an old chisel or similar tool along the inside of the rabbet.

Nothing further need be said about the rabbet, unless that its width is not important, provided it be sufficient to give an adequate margin to the glass. This, in the case of plain edges, may be taken as not less than ¼ in. Less would hardly do, though it may be, and often is, chanced, while more may be regarded as a waste of material, though, as will be seen later on, when treating of measuring glass, this does not necessarily follow. Plain-edged glass may or may not fill the entire space within the rabbet, as it is of little consequence whether it does or not. The same, however, can hardly be said of bevelled-edged plates, for in such cases the width of the rabbet most suitable may be stated as about ½ in. The reason will be given later on; and in the meantime it may be well to state that as it is, from various causes, not always practicable or convenient to get a rabbet of this width, the difficulty of a wider one may easily be overcome. Whenever practicable, the depth of the rabbet should be such that the back of the glass is below the surface of the surrounding woodwork. Sometimes this cannot be managed, but with a little forethought it generally can be—except, perhaps, in very small thin fancy frames, when the thin patent glass comes in handy.

The measurement of glass for furniture is by no means an unimportant item for the cabinet-maker to observe, not only in getting the actual measurement for the glass-cutter, but in setting out the work. A very short space will show the reasons for this. As is well known, glass is sold by the foot superficial. It is not, however, sold at one uniform rate per foot, irrespective of size, as the rate increases very considerably per foot as the plate increases in size. Thus the price might be, let us say, 2s. per foot super. for plates not over 2 ft., while a plate measuring 15 ft. might be charged for at the rate of 3s. 6d. per foot. It is, further, the custom to reckon a fraction of an inch as a full inch. Thus, a plate measuring 1 ft. on each edge would of course be charged at its actual superficial measurement of 1 ft., but if the dimensions of the plate are, say, 12¼ in. by 12⅜ in., it would be reckoned as a 13 in. by 13 in. plate, containing 1 ft. 2 in. super. Now, supposing that there is a rise of a few pence between the rate for under one foot and that for under two feet, it will be seen that for the sake of the two small fractions of an inch (which it is quite conceivable to suppose might have been dispensed with had a little ingenuity been exercised when setting out the working drawing) a considerably greater cost has been incurred, with only a very slight advantage in the size of the glass. In such a small size as has been named for the sake of illustration, the actual difference is neither here nor there, but it must not be forgotten that the same rule holds good whatever the size of the plate; and if this is a large one the difference in cost may be considerable. The cost of plate glass, whether transparent or silvered, is always by the foot superficial, but when it has bevelled edges an additional calculation must be taken into account. The cost of the bevelling depends on the width of the bevel, reckoned by ⅛ths of an inch; thus, when ordering or asking for quotations, it is necessary to specify ½ in., ⅝ in., or ¾ in., or whatever the desired width of bevel may be. This is reckoned at so much per foot-run, taking the edges of the plate all round, so that on a plate measuring 1 ft. on each edge there are 4 ft. of bevelling, which must be reckoned separately, and added to the cost of the glass otherwise. The custom of charging for fractions of an inch in the bevelling varies, but perhaps the usual plan is not to reckon anything under half an inch, and to charge anything above that as a full inch. Some dealers, however, charge all parts as a complete inch. The difference, in any case, is very trifling. For ordinary articles of furniture, and for moderate-sized plates of, say, anything under 2 ft. square, a ¾ in. bevel is suitable, though, if the extra cost be not objected to, it may be very well a ⅞ in. or 1 in. bevel. A great deal depends on circumstances, for there is absolutely no rule to go by, unless it be that the cheaper class of furnishing houses always, for very obvious reasons, have very narrow bevels on their glasses. When the rates for bevelling are quoted by a beveller or dealer, it must always be understood that the figures apply only to rectangular or round shapes, for fancy shapes, with inward curves or corners, are always charged considerably higher. Thus, it must not be expected that the ordinary rate would apply to such shapes as those shown in the diagrams that are given in page 40. The reason of this is on account of the increased risk of breakage during the process of bevelling. It not unfrequently happens that the beveller objects to give any quotation for such work, but charges for it correspondingly to the amount of breakage which has happened. In other words, the bevelling of irregular shapes must be done at the customer's risk. When a quotation is given, the customer may be pretty well sure that it is sufficiently high to cover the beveller's risks. Circular or oval plates are generally calculated for as if they were square-cornered, the longest measurements in each direction being taken.

In case the word "rate," which has been several times mentioned, might mislead any readers by inducing them to believe that a uniform tariff is adopted by all bevellers, silverers, and glass-dealers or merchants, let it be said that there is no uniform standard of prices, especially for bevelling and silvering. For the glass itself, there is a kind of standard or agreement among some, if not all, of the leading plate glass houses; it is, however, not rigidly adhered to, and the occasional or amateur buyer can hardly expect to be put on the same terms as the constant buyer for trade purposes. Occasionally a wholesale house may be found who will execute a retail or amateur's order, but the prices will naturally be more than for extensive or regular trade orders. It will therefore seldom or ever be to the advantage of the amateur to take much trouble to get in communication with the firm who actually supplies the glass and does the bevelling and silvering, for he will probably save nothing by so doing. Glass bevellers and silverers do not exist in every town of even a large size, but there are few without a good cabinet-making shop to which glass is supplied wholesale, either from London or elsewhere. Mind, when I say cabinet-makers, I do not mean mere house-furnishing dealers, because there are plenty of so-called cabinet-makers who manufacture little or nothing of what they sell, and they can seldom supply the amateur with glass at a reasonable price. Let him, however, go to an actual manufacturing firm of cabinet-makers who are in direct connection with a glass house, and he will probably find that he can do better than by buying direct himself. This applies especially to those who may be living in a place to which the prepared plates have to be conveyed by rail or other carrier: for the simple reason that perhaps the retailer gets several plates sent down at once, and by that means considerably reduces the cost of carriage on each. A single plate sent in a case by itself would cost nearly as much for carriage as if several more were packed in the same case. As plates are generally silvered and bevelled after they have been ordered—*i.e*, they are not kept in stock—it is necessary to give the order several days before the plates are required for use. From a week to a fortnight may be considered a fair time to allow. I have purposely refrained from giving any scale of prices, because these, on account of difference in quality and the various rates of carriage between the nearest wholesale dealer and wherever the purchaser may reside, could only tend to mislead. Any would-be buyer can easily ascertain the price at which he can be supplied in his own neighbourhood. It will be sufficient for him to name the size of the plates he requires, with the width of bevel, without troubling himself to know the rate per foot.

Having now given a few hints about glass as applied to furniture, the next thing will be to describe the actual fixing within the frames of the various kinds which are likely to find their way into the workshop. This, however, must be deferred to a future occasion.

## SOME RULES FOR CONTRIBUTORS AND CORRESPONDENTS.

To save trouble all round, Contributors and Correspondents, present and future, are earnestly requested to note and observe the following Rules, laid down for their guidance, and to adhere to them strictly. Compliance in every particular will save much unnecessary loss of time and waste of material and money in sending back through the post letters, articles, and drawings, to have such things done to them as have been left undone by the writers.

And first let me address Contributors who from time to time have been sending, or intend to send, papers for publication in Work; pointing out to them that the first paper on "The Violin: How to Make It," which appeared in No. 105, is, in every way, as far as arrangement goes, a *model paper*, showing throughout the proper way in which to write articles for Work. To this paper contributors are, and will be, referred, should occasion require me to do.

1. **Syllabus of Contents.**—The title of each and every paper must be followed, *first* by the name or *nom de plume* of the writer, as preferred by him or her; and *secondly*, by a brief synopsis or syllabus of the contents of the paper, comprising the sectional divisions of the subject matter of the article, and the subdivisions into which each sectional division is further divided. The title of the sectional division should form a side heading to the first paragraph of the section, to be set in a black letter as the side heading to this paragraph. Each subsequent paragraph of the section commencing a new subdivision should have its title, as a sub-heading, to be set in *italics*. It is desirable that sections should be broken up into paragraphs as much as possible. This mode of treatment will be found to facilitate reference, and, in a great measure, to cause each article to carry its index with it. Articles for printers should be written on *one side only* of the paper.

2. **Illustrations.**—Illustrations in every case must be drawn on separate paper, and not mixed up with the text in the manuscript, for the manuscript, if accepted, is sent to the printer, and the illustrations to the engraver. Every illustration must have its *inscription* written clearly beneath it, setting forth its number, as Fig. 1, Fig. 2, etc., and showing what it is intended to represent.

3. **Length of Articles.**—For the sake of variety of subjects and to interest as many readers as possible in each number, *ceteris paribus*, preference will always be given to short articles. Papers should range from one column as a *minimum*, to five or six columns as a *maximum*; and illustrations from one-eighth of a column as a *minimum*, to one page as a *maximum*, where the cuts are numerous or necessarily large. Contributors, however, should seek to attain a happy medium, and, whenever possible, to avoid reaching the maximum, either in subject matter or illustrations.

*** *In future, all Papers and Drawings in which these Rules have not been complied with will be returned to the senders for the insertion of omitted matter. The writers of accepted articles now in the Editor's hands must do what is requisite in the slip proofs of such articles, when sent to them for revision.*

A few words may now be addressed to Correspondents who write letters to appear in "Shop," or put questions therein, and to those who write answers to such questions.

1. **Letters.**—Let all letters be brief, and kept as closely to the point as possible. No personalities of any kind can be admitted.

2. **Questions.**—These should be put in as few words as possible, and every question should be written on a separate piece of paper, because questions on different subjects are, as a rule, sent to different persons for reply.

3. **Replies to Questions.**—In answering questions, the replies must be made as brief as possible. In replies running to considerable length, all redundant matter will be struck out, or the answer will be returned to the writer for reduction in length. When an answer cannot conveniently be compressed into a small compass, it is better to obtain permission from the Editor to treat it in the form of a short paper.

4. **Illustrations.**—These must be avoided in "Shop" as much as possible. In future, only such illustrations as may be positively necessary will be accepted.

*** *It must be understood that the preceding Regulations for Correspondence in "Shop" are necessary in order to lighten the pressure on that department of* WORK, *and to enable Replies to Questions to be given far more quickly than at present.* THE EDITOR.

## SHOP:

### A CORNER FOR THOSE WHO WANT TO TALK IT.

*** *In consequence of the great pressure upon the "Shop" columns of* WORK, *contributors are requested to be brief and concise in all future questions and replies.*

### I.—LETTERS FROM CORRESPONDENTS.

**A Useful Candlestick.**—W. J. F. (*Cork*) writes:—"The artiele here described does not claim to be ornamental, but I think there are few tradesmen or amateurs who would not at one time or other find it *useful*. We often hear the request from a worker for 'somebody to hold the candle.' This article, without altogether doing away with the necessity for 'somebody,' will do so in some cases, and that is an advantage. Its construetion is simplicity itself. It consists of a base and two sides. Tbe base may be any piece of waste wood, say, 10 in. by 4½ in. by 1½ in.; and the sides, say, 3 in. by 2 in. by ½ in. Of course, the sides may be as long as desired, and of any proportions; a higher eandlestick would require a larger base. The long edges of the base will be bevelled slightly towards the top; a ¼ in. of bevel will be enough for the measurements given. The sides are then nailed on to the base, and left loose at the top. It will then be found that they have a spring at the top strong enough to hold a candle. The inner parts that grasp the candle should be hollowed slightly with a gouge. The candle can be pushed up or down easily, and will remain in position. Thus you can make a candlestick of any height—8 in. or 9 feet if you wish. A smaller size, about 1¼ in. high, is very handy for bench use, and a great improvement on the 'piece of wood and four nails,' an arrangement which does duty in so many places."

Useful Candlestick.

### II.—QUESTIONS ANSWERED BY EDITOR AND STAFF.

**Relief Stamping.** — JOINT. — The specimens which you send are all very good. In the larger ones, where the line and a few of the letters are broken, the fault is but trifling; it may arise from several causes. First, the die may not have been properly filled up with colour. Use a good stiff brush, and daub well into the die. Secondly, your method of "wiping" or cleaning may be at fault. Try the old-fashioned style of "wiping" on paper, and, if possible, use hard paper—waste of cream-laid paper. Avoid thin "printing." Be sure that your "matrix" is sharp. The die itself might want "picking out" or touching up. I am inclined to think that your matrix has not been sharp enough. You will find this out by looking at the reverse side of the stamped sheet. The impression will appear lighter at the faulty parts.—G. C.

**Venetian Blinds.**—BENEDICT.—The rollers for the action may be obtained of any ironmonger, or at an upholsterer's warehouse. The article promised will soon appear.—B. A. B.

**WORK Index and "Shop."** — There is published a complete Index to Vols. I. and II. The "Shop" supplements are already paged.

**Speaking Machine.**—H. M. W. (*Blackpool*).—You want to know how to make a "speaking machine" in the simplest manner. Perhaps the article on the "Phonograph," which is to appear shortly, will take your fancy.—W. D.

**Glass Writing.**—A. H. (*Stratford, E.*).—The following matter on writing on glass is to be found in "The Art and Craft of Sign Writing," by Mr. Wm. Sutherland:—Chap. VII., Decorating on Glass; Chap. VIII., Gilding on Glass; Chap. IX., Gilding on Glass (*continued*); Chap. X., Gilding on Ground Glass, etc.; Chap. XI., Gilding and Ornamenting on Glass (the application of printing processes); Chap. XII., Embossed and Figured Glass; Chap. XIII., Embossing and Etching on Glass with Acids; Chap. XIV., Embossing Flusbed Glass; Cbap. XV., White Acid Method; Chap. XVI., Another Method of Embossing on Glass. If you require a copy of this work, you must hurry up, as there are only about forty copies left, and the book will not be reprinted. Queries cannot be answered by post.—H. L. B.

**Lacquering.**—C. B. (*Huddersfield*).—There must be something radically wrong somewhere if, as you say, you *invariably* get your lacquering streaky. This is often due to the separation of the brush—that is, the hair of the brush, etc., instead of keeping in one broad surfacc, spreads out in two or three portions pointed at the ends; the parts between the points thus do not get their share of lacquer. You can easily see if this is the cause in your case; if so, get better brushes, with a good body of hair in. The best "wrinkle" I can give you is to go in for the new American substitute for lacquer, which is now used by most of our leading brass manufacturers. It is called "Zapon," and is sold by the Fredk. Crane Chemical Co., 22, Newhall Hill, Birmingham; and Short Hills, New Jersey, U.S.A. I find it far superior to ordinary lacquer, both in ease of application and also in appearance, which is the chief thing after all; for, as you say, it is annoying after getting an article up to perfection, to spoil it in the lacquering, but with zapon there is very little fear of this, and the article looks just as handsome after lacquering (or zaponning, as it is termed) as it did before. For figured work especially it is suitable, as it preserves the finest hair-lines in all their metallic sharpness. It does not "set" so quickly as lacquer, which is an advantage on plain, highly polished surfaces, such as you speak about. I have no doubt that, from the reading of this, many will try a sample, as lacquering seems a "crux" for many; and, therefore, I append a few instructions for its use, trusting they will prove of service to you and others who may read them. In the first place, it is very important that as much care should be taken in cleaning the work, and freeing it from all grease, polishing material, etc., as in ordinary lacquering; and the zaponning should be done in a room which is free from dust and draughts, and the articles should not be handled, as the fingers leave marks on the polished surface, and grease as well. Articles to be zaponned do *not* require to be heated, another great advantage, but it is best applied in a warm room, and the articles should not be quite chilly. There are two ways of applying zapon—viz., by "dipping" and by "brushing." It is recommended to dip all articles that will admit of so doing, but in cases where, from consideration of expense or from the size of the article this is not practicable, brushing may be resorted to. In this case, the zapon should be flowed on with a full brush, care being taken not to brush over any part a second time until it has become dry, when any part that has been missed may be touched up again. Wave marks or brush marks will entirely disappear when dry. Should the articles peel after coating, the cause is grease. The foregoing remarks apply to "Dip Zapon." "Brush Zapon" should be applied as thin as possible; therefore, wipe the brush free from all excess, the same as in ordinary lacquering. Brush once only over the surfacc to be covered, and allow it to dry; a second coat may then be given if desirable, but it is not necessary if the work is covered. It can be had colourless, and in various eolours, gold, green, etc., etc.—R. A.

**Bird Cages and Wire Baskets.**—KENT COAST. —Consult the Index to WORK, Vol. II., for Bird Cages. Wire-working in all its branches is treated in this volume, and commenced in No. 105 of WORK.

**Speaking Tube.** — J. McD. (*Glasgow*). — You need have little fear of your speaking tube not acting, provided you take care to fit it up properly. Use good tubing, about ¾ in. internal diameter. Be sure that the joints are quite sound and air-tight, and that the interior surface is quite smooth. You could, of course, use telephones, but they would be much more costly. A complete installation, including bells, switches, etc., would cost £5 or £6. Messrs. Cox & Co., 11, Fetter Lane, would supply you with all requirements for the above sum; you could easily fit them from their instructions.—W. D.

**Paper Cap.** — CARADOC. — It is extremely easy to make these caps, but extremely difficult to explain clearly how it is to be done. However, with the help of diagrams, I hope to be fully understood. First, make the paper exactly square, three times the size of the crown—thus for 7 in. square cap, the paper must be 21 in. by 21 in.; for 6½ in. cap, 19½ in. by 19½ in.; for 6 in. cap, 18 in. by 18 in. Now spread your paper flat out before you as in Fig. 1, and on the diagonal line A B fold the point C on D, crease it, and again spread out the paper flat; and in like manner on C D fold the point B over A, crease it, and flatten out again. Secondly, fold the square into thirds, first on the line E E, and next on F F (see Fig. 2); then fold the strip again into thirds on G G, H H (see Fig. 3). Now spread the paper out flat. It will then be seen that the square G G, H H will form the future

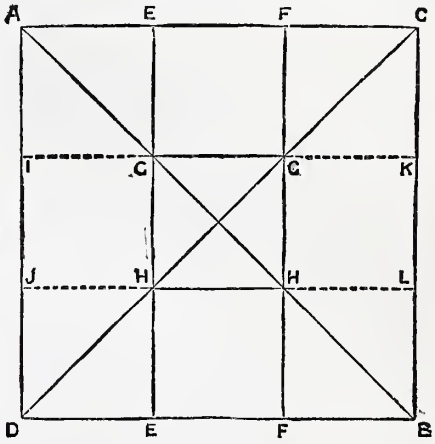

Fig. 1.

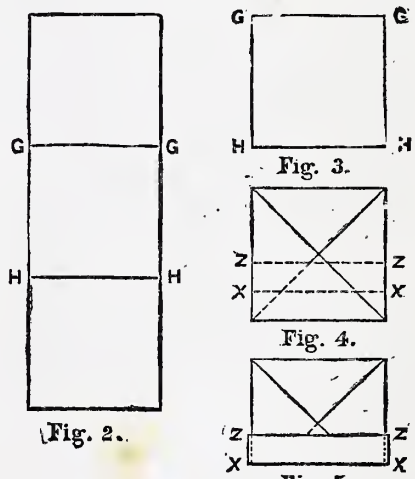

Fig. 3.

Fig. 2.

Fig. 4.

Fig. 5.

Paper Cap.

crown, whilst E F, G G, and H H, E F will form two plain sides when the said sides are folded at right angles to the crown. In Fig. 1 all the outward creases are drawn in full line, whilst the inward ereases are only dotted. Now to form the other two sides of the cap, and at the same time to maintain the plain sides in their proper position. Fold down and pinch together on tbe respective lines A G, H D, H B, and G C, tbe small squares A E I G, J H D E, H L F B, F C G K into triangles, and fold them against the two sides I G J H, G K H L, with D upon I and A upon J on one side, and B upon K and C upon L on the other side (see Fig. 4). Now fold up all round about 1 in. of your four sides (see Fig. 5), and proceed then to turn up a second time all round at X X and Z Z, thus forming a band which will firmly hold the cap together.—J. W. H.

**Scene Painting.**—FRETWORKER.—Articles upon this subject have already appeared in Vol. II. The other subject you refer to will be treated in due course.

**Poles of Magnetic Needle.**—AMATEUR.—You are quite right. The north pole end of the compass needle is, strictly speaking, the north-seeking end of the needle, and is therefore the south pole of the magnetic needle employed in the compass. But this end, by common consent, is regarded as the north pole of the needle, and the relation of other magnets to this is determined accordingly. In converting a steel bar into a bar magnet by enclosing it in an electrical solenoid, we regard the end to the left of the course of the electric current as the north pole end of the magnet.—G. E. B.

**Charge for a Voltaic Battery.**—R. L. (*No Address*).—If the battery is intended to be a Bunsen, charge the cell containing the zinc with one part sulphuric acid in from eight to twelve parts of water. Allow the mixture to cool before placing it in the cell. Charge the cell containing the carbon with strong nitric acid—no water in this. The acids must not be mixed together. The carbon plates should go in the porous pots with the nitric acid, leaving the outer and larger pots for the zinc cylinders and the mixture of sulphuric acid and water.—G. E. B.

**Rendering Parchment Transparent and Waterproof.**—BANNERMAN.—So far as I understand his requirements, I imagine that BANNERMAN might get what he wants by following the process sometimes resorted to for making imitation oil paintings from old mezzo-tinto engravings. To do this, the back of the print is covered with repeated coats of *mastic* varnish till it becomes transparent; oil colours, chiefly in flat tints, are then laid on the back. The best advice I can give to BANNERMAN is to try the mastic varnish in this way. As I do not know his purpose, I cannot say positively that this will give as much transparency as he requires, but I presume that it will; and it will certainly make the parchment waterproof, without impairing its strength, which are points upon which he insists. Of course he must take care that his parchment is of uniform thickness, or it will not appear equally transparent in all parts.—S. W.

**Alarum Clock.**—C. K. (*Mildmay Park, N.*).—Take out the movement, and on the arbor that carries the alarm hand (that is, if a lever; you do not say if a lever or pendulum) between the plates is generally a spring to hold the arbor tight. This spring may have got loose by the pins coming out; if so, pin it up tight. Or perhaps the wheel that rides loose on the arbor, and has a notch cut in the edge of the collet or sleeve, and is pressed against a pin going through the arbor, gets fixed in rising up the slope. Smooth the slope up nicely, also the pin, and put a little oil, then try. Or perhaps the arm on the hammer is bent down out of the way of the hook or up too hard against it. I think you will find one of above faults with it.—A. B. C.

**Enamelling Metal.**—J. P. (*Bethnal Green*).—The so-called enamel, such as is applied to bicycles and tricycles, is simply a fine japan, but enamel has somehow a better sound, or is considered a more taking name, so I suppose that is why the vendors of such articles so term it. Such being the case, we naturally arrive at the conclusion that it is applied in the same way. And as to the question whether it is too difficult for an amateur, that depends upon whether the amateur is prepared to go to the expense of erecting an oven large enough to stove the parts in, for this is the secret of good enamelling, or japanning, whichever you like to call it. If, as is most likely the case, you are not prepared to do this, there are for your choice the various articles advertised for this purpose, such as Foochow, Guest's, Aspinall's, etc.: you will find their prices and addresses in any issue of the cycling papers. They answer their purpose fairly well, but are not to be compared with stoved work. I am a bit of a cyclist myself, and when my "steed" requires a fresh "coat," I purchase a little best black japan (*not* Brunswick black) and a little of the best carriage varnish that I can get for money. Two coats of the black and one of varnish, and I have a nice-looking machine again, and the renovation costs not more than 1s. 6d., and lasts a whole season, which is as long as I care for. Moral—Go and do likewise.—R. A.

**Lamp for Box Battery.**—A SUBSCRIBER.—I infer your lamp to be a 10-volt 8 c.p. incandescent electric lamp. As you cannot light such a lamp with current from a small 4-celled box battery, the fault lies more in the selection of lamp than in the construction of the battery. The lamp should only require from 6 to 8 volts—six, rather than eight—but not higher than the latter figure, or you will get no light at all. Mix the bichromate of potash solution with the sulphuric acid in a stoneware jar, and allow the liquid to cool before placing it in the cells. The brass tang may be soldered to the zinc if the joint is well made, and the lead heads for the carbons may be square instead of round, without in any way interfering with the working of the battery. Add another cell or two to your battery if you are going to use the same lamp, and you will then get a light from it.—G. E. B.

**Drilling China.**—H. P. (*Brighton*).—The best and easiest way is to drill with a chip of diamond set in a tube, and used with a special drill, such as is illustrated in the article upon "China and Glass Riveting" in No. 53 of WORK. Read this article, and if it is such work you wish to undertake, you will, I think, gather some useful hints from it.—W. E. D.

**Stuffed Bird-Case.**—F. M. (*No Address*).—I send a sketch of bird-case. To make it, proceed as follows:—Procure a piece of pine 3 ft. 4 in. long, 2 in. wide, and 1¼ in. thick, and plane it up, then run a rabbet ½ in. wide and ¾ in. deep (as per sketch A, Fig. 3) for the bottom board to rest in; then run the rabbets and mould as Fig. 3, B, then procure a piece of pine 1¼ in. square, 7 ft. 6 in. long; cut off a piece 3 ft. 7 in. long, and after planing up square, run a rabbet ¼ in. by ⅜ in. down each side as per sketch (Fig. 4), then take the other piece and rabbet it ¼ in. by ⅜ in. down one side only, and down the other a rabbet ½ in. each way; this is for the back to rest in (Fig. 5). Get another piece 3 ft. long, and plane up as Fig. 6; this is for the top frame. We will now make the framework. Take the piece of base framing and cut a piece off 1 ft. 7½ in. long with a mitre at each end, then cut two more pieces 7⅞ in. long with a mitre at one end only, and proceed to glue and nail them together like Fig. 7, with the large rabbet inside. Now take two pieces like Fig. 4, 1 ft. 9¼ in. long, and cut a bit out at one end from corner to corner of each rabbet as per dotted line, and ½ in. deep; this will allow the front pillars to rest on the base frame at the points C, C. Now, if you place the front pillars on the base frame, you will find that the rabbets are exactly in

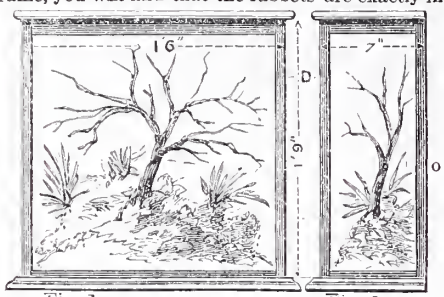

Fig. 1. Fig. 2.

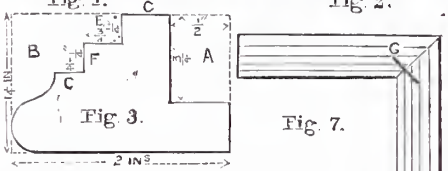

Fig. 3.

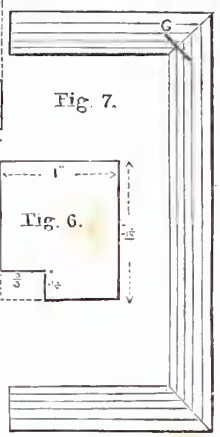

Fig. 7.

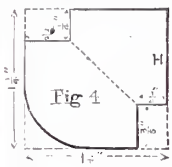

Fig. 4

Fig. 6.

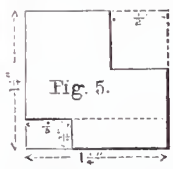

Fig. 5.

**Stuffed Bird-Case. Fig. 1.—Front. Fig. 2.—End. Fig. 3.—Base Frame. Fig. 4.—Plan of Front Pillars. Fig. 5.—Plan of Back Pillars. Fig. 6.—Top Frame. Fig. 7.—Mitred End.**

one place, and by cutting the corner of the base frame down to C (Fig. 3) as per line G (Fig. 7), until the front pillars are on a line with F (Fig. 3), you will be able to glue and nail them in position as shown in Figs. 1 and 2 (D, D). Now take the piece that you have rabbeted (Fig. 5) and cut two pieces off 1 ft. 9½ in. long each, and then cut them as per dotted line (Fig. 5), and ½ in. deep, care being taken that you do not cut the wrong end, as all the rabbets that are ¼ in. by ⅜ in. must come together for the glass to fit in. Now, if you put the piece on Fig. 7 with the rabbets in place, you will see that you can cut a piece out of the end of the base frame end 1 in. long and ½ in. deep, which will let the ends of the back pillars rest on C, C (Fig. 3), the same as the front pillars. Now take the piece of top frame and cut a piece 1 ft. 4 in. long, and cut a piece out of each end ¼ in. long and ⅜ in. wide from the back; this will allow it to fit into the rabbet of the front pillars and also the back of the same at H (Fig. 4). Now cut two more 5 in. long for the ends; cut them the same as the front, and glue and nail all firmly together. Now take a piece of ⅛ in. pine, 1 ft. 7½ in. long and 7⅛ in. wide, plane it up, and round the edge off on three sides, leaving the back square. Now proceed to glue and nail it on the top, letting it project ⅛ in. on the front and sides only, and you will have frame like Figs. 1 and 2. Now take a piece of board and fit it in the rabbets of the base frame in the inside for the bottom of the case, then procure sufficient board to make the back, and let it just drop inside the rabbets of the back pillars, so that it will come flush with them at O (Fig. 2). You can now use your own taste in blacking or gilding the frame, but if the front pillars are stop-chamfered and picked out in gold, with the other parts ebonised, you will be quite satisfied with the looks of the case. Now put in the glass, or you can fasten in the back, covering it with calico stretched tight to paste the paper on, and after pasting the paper on and distempering the back and top and the inside of the front pillars, you may make your rockwork or tree on a separate board and slip it inside the case, fastening it down with screws. You can now head in your glass and black the back of the case with glue and lamp-black. Of course, you can use your own taste for the front pillars, but I do not like turned ones; they are not as neat as one that is stop-chamfered and beaded like the moulding you buy in black and gold.—J. A. W.

**Stain.**—S. S. (*Salford*).—To stain birch a mahogany colour is not difficult. As good a stain as any for the purpose is a decoction of logwood chips in water. Test the strength on a piece of waste wood before using it on anything of value. Your question about matching up teak is one that cannot be answered satisfactorily, for in this class of work no definite directions can be given. One might just as well ask how an artist gets effects in a picture, and then expect to do the same when one gets to know the paints he uses, without having any knowledge of the art of painting. Matching-up is an art which may to a certain extent be learned under a good teacher, but hardly at all from verbal instruction. I should experiment with those pigments which seem most likely to give the tints you want, and carefully note the results. The various shades of brown are most likely to be useful to you.—D. D.

**Ebonite.** W. A. N. (*Forest Hill*).—I do not know of any material by this name, but from your description it is probably the same as vulcanite. If so, it can be got from any shop where indiarubber goods are sold. It can be cut with a saw and other tools. I presume you want it for fret-cutting. It is not very pleasant to work with—at least, not so much so as xylonite, with which there is not the slightest tendency to chip. However, your best plan will be to get a small piece of each, and, by trial, ascertain which of them suits you best.—D. A.

**Varnishing and Polishing.**—T. B. (*Dodworth*).—What you ask for are apparently full directions for both polishing and varnishing, as well as staining—in fact, a complete guide to the work. To give this is, of course, out of the question in "Shop." As you say you are quite unacquainted with the art of polishing, I am afraid I must ask you to wait a bit before your wishes can be gratified; but in the meantime, you will do well to read over the numerous hints on the subject which have already appeared in these columns. Perhaps it may be of assistance to you to recommend you to buy stains ready made, and to varnish with a brush instead of polishing with a rubber. Copal or any hard clear varnish will do for the purpose. I hope these hints will be of service to you. If you find any difficulty, let us know, and we will do what we can to help you, but it is impossible to give a novice full instructions for the practice of a difficult art in all its phases in "Shop," or even in any one number of WORK.—D. D.

**Safety Cycles.**—J. W. H. S. (*Sharow*).—A series of articles on this subject will appear in this volume of WORK.

**Silvering by Nitrate.**—G. O. M. (*London*).—There are several recipes given for this, but perhaps the two following will be as easy for you as any:—(*a*) Dissolve ten grains of pure nitrate of silver in 1 oz. of water; stir with a glass rod, and drop strong ammonia in until the brown precipitate is redissolved. Make separately a solution of ten grains of Rochelle salt in 1 oz. of water. Clean the glass well, and warm by the fire or in the sun; make a wall of putty, beeswax, or other suitable substance round the edges to prevent the liquid flowing off. When ready, pour on sufficient of the two solutions to cover the glass to a depth of about ¼ in., using two parts of the nitrate to one part of Rochelle salt. Let it stand, if possible, in the sunshine for an hour or two, until the silver is deposited; then pour off what remains, and wash four or five times with soft water; let it dry, and finish by varnishing either with equal parts of beeswax and tallow, or one composed of gum dammar, twenty parts; asphalte, five parts; gutta-percha, five parts; and benzine, seventy-five parts. This latter sets very hard. (*b*) Dissolve 1 oz. of nitrate of silver, ½ oz. of spirits of hartshorn, and 2 oz. of water; filter; then add 3 oz. of spirits of wine or naphtha, and about twenty-five drops of oil of cassia; let it remain a few hours, when it will be ready for use. Prepare the glass in the same way, and pour on the solution; then drop into it, in different places, a few drops of oil of cloves and spirits of wine (one part of oil of cloves to three parts of spirits of wine). The more oil of cloves the quicker the deposit, but too much should not be used. Finish off in the same way as in the first recipe.—W. E. D.

**Mould for Lead Heads.**—H. F. F. (*Hackney*).—The mould for the lead castings on the heads of carbon plates used in Leclanché cells may be made of any moulding material, such as sand, loam, or plaster of Paris. Get an old carbon, and use the head of this for a pattern. The carbon plates have the heads cast on them head end downward, resting on the tang of the binding screw thrust into the bottom of the mould. An iron mould, cast to the shape of the lead head, will turn out the sharpest and best finished castings, and can also be worked at a faster rate than moulds made in sand or in plaster of Paris.—G. E. B.

**Carbon Plates.**—F. W. (*Addlestone*).—If the gas retort carbon is dense, close-grained, and hard, the plates cut from it will do equally well with those bought elsewhere. Use an old saw or one improvised from hoop iron, plenty of wet sand, and elbow grease without stint. It is a dirty and a laborious job.—G. E. B.

**Slides of Brass Wind Instruments.**—YORKIO.—Heat the outside of the slides over a gas jet, taking care not to fuse the solder. Pour a little *oil* (not paraffin, which is not a good lubricant) on the junction of interior and exterior slides. When the oil has been drawn in through the action of the heat, pass a narrow slip of stout linen or canvas through the bow of slide, and fix the ends in a vice, or tie them round some fixed object; then pull the instrument steady and firmly. If the slide cannot be now drawn, the bow must be unsoldered, and each side be attacked separately. For this purpose a small mandrel (which can be made in wood), to fit tightly the bore of slide, is required. When inserted in the slide, it should project sufficiently to give you good purchase. Then, after again heating and oiling, try and turn the slide, drawing it at the same time firmly toward you. Should this fail, there is probably a bruise in the slides, and it is a case beyond amateur curing. Send the instrument to the maker. If the bruise cannot be taken out by acting upon the suggestions given on page 780 in No. 100, you had better send it to a maker. Any attempt to straighten the bow of hell would almost certainly result in cracking the tubes; and even if you succeeded in escaping this danger, you could not bend it back to its original shape again.—G.

**Tobacco.**—N. M. (*Norwich*).—Tobacco plants are raised from seed, which, in this country, is commonly sown in heat (in a frame, pit, etc.) in the month of March, the seedlings being pricked out into small pots, and not placed in the open air till the mild weather of June has set in. Or, in the open air, the seed is sown in sunny borders early in May. The tobacco plant loves a warm, sheltered spot, with a southern aspect. It is very susceptible to cold east winds. It requires a rich soil—to plant it in any other is indeed seed and trouble thrown away. It should have a deep, free loam, or ground deeply trenched with well-rotted manure. In dry weather it needs an abundance of water. For the purposes of commerce, the plants are cut when the leaves begin to change to a yellowish-green. They are first laid upon the ground to dry, the thicker stems being slit through to facilitate drying. Afterwards they are hung on poles, so that the air may have free access to them. If, as is often the case in this country, artificial heat is needed to assist, it must be of a very gentle kind. When just sufficiently dry (not so dry as to break), the tobacco is heaped together on wooden platforms to ferment or "sweat." The drying and sweating are very delicate operations, and much care and skill in them are required to produce a high-class article.—A. Y.

**Silvering Mirrors.**—E. T. (*Blackburn*).—Several replies have been published upon this subject during the last few months in WORK. The process is as follows:—A piece of tinfoil is covered with mercury (quicksilver); a sheet of paper is laid upon it, and the glass upon the paper, which is then withdrawn, leaving the glass resting upon the foil and quicksilver; it is then weighted down until dry. Although this sounds rather easy, in practice it is the reverse, and the larger the glass the more difficult it becomes for an amateur.—W. E. D.

**Hydrofluoric Acid.**—ETCHER writes:—"Can you tell me how the white acid used in glass-etching is made?"—By white acid, I suppose you mean hydrofluoric acid ($H_2F_2$), or fluoric acid, as it is sometimes called. It is made as follows:—Powdered fluoride of calcium is placed in a leaden retort, and twice its weight of sulphuric acid (oil of vitriol) poured upon it, and by means of a stick is made into a paste; it is now gently heated, when gas is freely given off; this must be collected in another leaden vessel containing water. The water absorbs the gas, and it is continued until it will take up no more. The water is thus highly charged with acid, and is the liquid hydrofluoric acid used in etching glass. Great care must be used in making it: the operation ought to be conducted in the open air, as it acts injuriously upon the organs of respiration. The vapours produce pain at the finger-ends, and drops on the skin act like a red-hot iron, producing painful sores; it must also be stored in indiarubber bottles, as it corrodes and dissolves glass. Should you only need a small quantity, it is far better to buy it than to make it, on account of the difficulty and danger. You ask "how the designs are put on." The glass is coated with Brunswick black, beeswax, or some other substance that will resist the acid, and the design is cut through that down to the wax. Designs are cut with wheels of different diameters, mounted in a lathe, and wetted with emery and oil.—W. E. D.

**Coloured Views.**—A. E. S. (*Glasgow*).—I cannot decide to what class of articles you refer when you ask for the process of producing "coloured view articles," such as are sold at "coast fancy goods stores." Now there are several kinds—some being coloured photographs, and mounted in optical contact with glass. Some small articles are simply coloured prints in optical contact with glass; others again may be printed in inks, such as common earthenware is done with. Perhaps this is what you mean as you mention ink. How did you make your ink? Did you use metallic colours? None other are of any use with glass or pottery. This probably was the cause of your failing.—W. E. D.

**Engine Power.**—G. D. (*Sheffield*).—If there is no expansive working—that is, if the initial pressure of 60 lb. is continued to the end of the stroke—you would get, allowing for friction, about a ½ h.p. from your engine, rather under than over perhaps. By calculation, it would come out ¾ h.p.: thus,

$$\frac{\text{pressure} \times \text{area of piston} \times \text{velocity in feet per second}}{33000}$$

$$= \frac{60 \text{ lb.} \times 3{\cdot}1416 \times 133 \text{ feet}}{33000} = {\cdot}75 \text{ h.p.}—\text{J.}$$

**Camera.**—H. W. (*Gateshead*).—The shutter most generally approved for studio work is Cadett's Patent Shutter, which is simply a flap shutter attached to the back of the lens mount and worked by the expansion of a small bellows working between the sides of a case with a movable lid, to which the shutter is connected. The pneumatic principle of action is, of course, the same in all shutters, being the expansion in a small air-tight bag at one end of a tube by the compression of a larger one at the other. A variety is made by the propulsion of a small sealed tube from another open one, in which it slides, the sealed tube pressing upon a lever or trigger as the case may be, as in Fig. 1. The dotted lines show the indiarubber tube connected with a ball, from which the air is forced by pressure with the hand; A represents the short sliding tube with stops. The advantage of having the shutter work at the back of the lens inside the camera is that it can be used without attracting the attention of the sitter, an important matter where children are concerned. The shutter itself is made of a frame of bent wire, over which black velvet or cloth is stretched, and of a size sufficiently large to cover, and a little to spare, the lens to be used. The attachment consists of a ring of wood covered with cloth, with a loose piece that can be pressed against the lens mount by means of a thumbscrew, as in Fig. 2. The manner in which the flap is raised and lowered is that the wire framework, which

Fig. 1.

Fig. 2.
Camera Parts.

works on a bar above the lens, is brought down on one side in the form of a short lever, against which the pneumatic arrangement presses, thus raising the flap. A piece of elastic is stretched across the flap a little below its point of suspension, that immediately on the removal of the pressure brings it (the flap) back to its original position over the lens. There is a great variety of methods of utilising the air pressure and forms of shutters, but up to the present time for studio work the simple flap is preferred. With regard to the other questions, the use of hinges in sliding frame is that a longer extension of the camera may be had than if it were only the size of the solid unhinged part of the baseboard. In the diagram shown, it will be seen that without hinges the frame would prevent the closing of the baseboard, which, although not perhaps clearly shown, does fold up, the shorter piece being of the width of the front woodwork of the camera. The bent wire acts as a spring when either one or both of the shutters are in place, and the use of it is to stop out the light by pressing one of the strips of wood to cover the opening on the withdrawal of the shutter, and the spring is got by the pressure of the wire against the shutter that remains in place. If the division between the plates is too thick for the plates used, there is no objection to making it of thin zinc or other metal blackened. The buttons that keep the plates in position are sunk level with the framing. The less play between the division and plates the better, so long as there is room, making allowance for the varying thickness of the glass in general use. If metal is used, a weak spring fixed on each side is an advantage. Some prefer a piece of blackened eardboard, slightly buckled. The idea is to keep the plates in proper register by pressing them gently against the buttons in front, whatever may be the plan used to effect it.—D.

**Engine, etc.**—C. S. W. (*Settle*).—It will be quite sufficient to add the names of the towns only in which the firms you name carry on business, provided you put on the envelopes the nature of the business. If you want a model, you cannot do better than advertise in WORK. There will probably be an horizontal engine described in WORK shortly.—J.

**Paper-Making Machinery.**—H. W. C. (*Lee, S.E.*).—We do not see why the idea should not succeed, and it appears to be novel. If it does the work proposed, it would probably be worth patenting.—C. E.

**Electrotyping.**—ELECTRO.—(1) The wires leading from the dynamo to the vat get hot, because they are not large enough to carry the current required in the vat. The sulphate coating has nothing whatever to do with the heating. (2) If the wire from the negative pole of the machine is connected to a stout metal bar on which the slinging wires or clips of the moulds rest, and the wire from the positive pole of the machine is connected to a similar stout metal bar supporting the anodes, there should be no necessity to connect the wires at both ends. The resistance is not at these points, but in the leading wires themselves. (3) Electrotypes for the press are mounted on wood blocks, the whole being made "type-high." Electros on metal are employed for ornamental purposes. The prices charged for these are variable.—G. E. B.

**Nickel Bath.**—B. J. (*Dorking*).—To make up twenty-five gallons of nickel solution for plating, procure ½ cwt. of double sulphate of nickel and ammonia. This will cost about 23s. from such firms as Messrs. J. E. Hartley & Co., 13, St. Paul's Square, Birmingham. Dissolve the nickel salt in hot rain-water, and filter it through calico into the vat; then fill up with filtered rain-water. The solution should be neutral to blue litmus paper, and have a specific gravity of 1·520, as tested by a direct reading specific gravity hydrometer. If it is acid, the acidity must be corrected by adding sufficient liquid ammonia. If the solution is too dense, withdraw some of the liquid into another vessel, and fill up the vat with rain-water. As a rule, use 1 lb. of nickel salts to each gallon of water. Work with a large surface of pure nickel anode, obtainable where the salts are to be obtained.—G. E. B.

**Pencil-Holder.**—PEN.—We have examined the description and sketch sent us, and it appears to be a useful and practical idea, but whether it is a novelty we could not say without a search to ascertain if prior rights have been established by anyone. There is not the least doubt but that many less promising inventions are patented daily; but before taking any steps in regard to patenting, you should make, or have made by a competent person, such a search as would decide this important point, and then you will be in the proper position to consider what you had better do in the matter.—C. E.

**WORK Volumes.**—FAIERO.—You should address the publishers—Messrs. Cassell & Company, Limited, London, E.C.—but the price of a WORK volume (7s. 6d.) is so small that it will be hardly worth your while to write about the cost of exchanging numbers for a volume.

**Model Electric Lights.**—F. E. O. (*No Address*).—Articles on the above subject appeared in WORK, Nos. 76, 82, 89, 92, 94, 97, 99, 100, and 104. They can be had through your bookseller, or from the publishers, Messrs. Cassell & Company, Limited, London, E.C.

**Harmonium Reeds.**—It is useless to place harmonium reeds on pipe organs, as the reeds will not keep in tune with the pipes. Change of temperature, which will lower the pitch of the pipes, will heighten that of the reeds, so that the resulting difference is considerable. The only thing practicable is to add a set of reed pipes, a small trumpet for loud stops, and an oboe or clarionet for softer tones. You do not say what stops your organ is to contain, so I am unable to advise as regards any additional flue pipes. As regards a black stain for wood, I do not think you can get anything to sink deep into the wood unless it is put on boiling hot; but perhaps some other contributor may be able to assist you in this matter.—M. W.

**Marbling Colours.**—W. J. J. (*Southwick*).—Marbling colours ready ground, in air-tight tubes, which I mentioned in my articles on "Bookbinding," may be obtained in large or small quantities from Messrs. Berry & Roberts, St. Bride Street, London, E.C. They vary greatly in price.—G. C.

**Stitching in Binding.**—NIL DESPERANDUM.—I have not the slightest idea of what you want. Here is your query: "Is there no other way of stitching other than stitching through the cardboard and buckram in bookbinding; and if so, will you kindly let me know?" Write again, and try and explain your difficulty a little more definitely.—G. C.

**Stamping.**—J. S. (*Amsterdam*).—You have used Dutch metal instead of gold-leaf, which is really the cause of your failure. But if you follow carefully the instructions given on the page you quote, use real gold, and use the powder supplied by Mr. W. Valters, 1, Pembroke Terrace, The Park, Salisbury, Wiltshire, you will have the best stamped silk, satin, or velvet in Europe. Do not use bronze powder or Dutch metal, which, although cheaper in the first cost, turns out the most expensive in the end. When you have tried the powder, you might report, as I would like to know if you succeed to your own satisfaction.—G. C.

**Index to Vol. I.**—L. K. (*London, S.E.*).—An Index to Vol. I. of WORK has been ready since the volume ended, and has been advertised many times in WORK. The price is 1d., or post free for 1½d., from the publishers, Messrs. Cassell & Company, Limited, London, E.C. The Index to Vol. II. is now ready, price 1d.; post free, 1½d.

**Gutta-Percha Soles.**—WEEKLY READER.—An article on the above subject appeared in WORK, No. 102. It was entitled "An Easy Method of Resoling Boots." This will suit you, probably.

**"Patent."**—D. K. (*Dumfries*).—Provisional protection gives no *legal* right to the use of the word "Patent." The legal right to do so is only acquired when the patent has actually been granted.—C. C. C.

**Violin Papers.**—J. B. (*Broomhead*).—These will be given in Vol. III. of WORK, now commencing.

**Book on Practical Blacksmithing.**—WASSE.—The name and address of the publishers of the above work, noticed in "Our Guide to Good Things," No. 89 of WORK, is given at the end of the notice. Write to the publishers for the price of the book.

### III.—Questions Submitted to Correspondents.

**Pendulum.**—HORA writes:—"Will anyone give me the dimensions for a half-seconds compensated zinc and iron pendulum—viz., length of suspension spring, length of steel or iron centre rod, length of zinc tube, and length of external iron tube, the bob to be centrally supported? What thickness of the above tubes is required for a bob weighing, say, seven pounds?"

**Enamelling Slates.**—J. D. (*Holyhead*) writes:—"I should feel obliged if any reader would give me information of any book or treatise upon enamelling, especially slates; or, possibly someone can give me information as to how to do this work."

**Coppering.**—A. K. (*Edinburgh*) writes:—"Can anyone give me a recipe for a solution for coppering lead or tin?"

**Hair-Sieve Bottoms.**—HOOPBENDER writes:—"Can any reader oblige with the addresses of two or three makers or dealers of hair-sieve bottoms?"

**Doll's House.**—W. L. (*Penge, S.E.*) would feel obliged if any reader could tell him where he could buy such fittings as small door-handles, knockers, and fire stoves.

**Coopering and Chairmaking.**—J. S. (*Longsight*) writes:—"I should be glad to know the opinion of an expert as to what advantage there is to coopers and chairmakers in the wooden brace, etc., over the iron one used by joiners and others."

### IV.—Questions Answered by Correspondents.

**Scrap Leather.**—J. M. (*Manchester*) writes, in reply to A. F. W. (*Oldham*) (see page 829, Vol. II.):—"You ought to experience no difficulty in disposing of any reasonable quantity of scrap leather. Try Platt's or Asa Lee's in your town, who use it for case-hardening purposes. Another market for it, or any other animal membranous refuse, is the manufacturing chemist, who makes ferricyanide of potassium, or 'prussiate,' as it is often called."

**Iron Lasts.**—F. M. (*Ebbw Vale*) writes, in answer to W. S. (*Highbury*) (see page 830, Vol. II.), *re* Iron Lasts:—"He could get them from J. & H. Cooper, 35 and 37, Caledonian Road, and 1A and 2A, Albion Street, King's Cross, London, N.; or from W. Beaney, London. I forget the latter's full address, but he could get it from the *Shoe and Leather Record*, price 2d. They are sold both by the pair and by weight, according to the kind he wants. The former range from 11d. per pair for children to 3s. for men; and the latter, from 9s. 6d. to 15s. per cwt. Full information can be got by applying to either of the above for price list."

**Hair Cloth.**—H. E. (*London, N.W.*) replies to G. J. W. (*Ballymena*) (see page 830, Vol. II.):—"You can get hair cloth of Tubbs', upholsterer's warehouseman, Goodge Street, London, W. Price about 1s. 6d. per yard for 18 in. wide, to about 4s. 6d. for 36 in."

**Circular-Saw Bench.**—E. H. H. (*Chatham*) writes, in reply to S. P. (*Penarth*) (see page 782, Vol. II.):—"Let him get some 4 in. by 3 in. fir, and set out four rails in pairs, for three uprights—one in middle, and others about 9 in. from ends; then brace from top of middle stile to bottom of end stiles; then mortice and tenon a piece across top and bottom of ends, and your framing is complete, although for heavy work the ends should be braced. Use 4 by 2 for braces; for top, get some 1½ by 9 fir, and screw down to framing, and then cover with stout sheet iron, screwed down. If S. P. gets a list from Reynolds & Co., Britannia Co., or any of the leading machine makers, he will get all the information he desires, and get better ideas from their illustrations than can be given in writing."

**Draw-Knife.**—LONDON STAIR BUILDER writes, in reply to W. W. M. (*Glasgow*) (see page 830, Vol. II.):—"You should write to Melhuish, tool dealer, Fetter Lane, London, E.C. I think they could supply you with the draw-knife and chamfer gauge. I fancy the latter is a Yankee invention, and costs 60 cents in the United States of America."

**Plate Rack Rods.**—J. B. F. (*Eastbourne*) writes:—"*Re* your answer to J. N. (*Erith*) (see page 812, Vol. II.), what he wants is supplied by the Cheap Wood Co., 72, Bishopsgate Street Within, E.C., under 'Sash-Bars and Rounds,' No. 289, and costs 2s. 1d. per 100 feet."

**Impressions.**—DUBLINIENSIS writes, in reply to H. M. (*Leeds*) (see page 781, Vol. II.):—"Some years ago I wanted to do a similar job, to send the impression abroad for purpose of recognition by a supposed owner of the book. I managed it very fairly thus (I must first say the impression was in *intaglio*):—I placed the book in a box, the edges of which were about an inch higher than the book, first covering the gilt edges with brown paper, lapping the edges inside the covers; then I got some nice tissue-paper, and damped it on both sides with hot olive oil with a flat camel-hair brush, laid it evenly on cover, and covering this with hot very fine silver sand to about ½ in. thick, smoothed it, and then laid over that an even-surfaced board, which was weighted down with two half-hundred weights, and let it remain a couple of days, when I removed all, and found I had an excellent cameo impression."

**Band-Saw Machine.**—TEAK writes, in reply to J. H. (*Sheffield*) (see page 765, Vol. II.):—"He will find suitable machine by sending 6½d. for catalogue (of six hundred engravings) to M. Tiersot, 16, Rue des Gravilliers, Paris."

**Castings.**—PARTICK writes (see page 782, Vol. II.):—"If J. D. (*Glasgow*) will communicate with . Munro, 1, Ewing Place, Partick, he will get the desired information."

**Screen to Fold Both Ways.**—W. S. (*Rugby*) writes, in reply to F. C. (*Swanley*) (see page 780, Vol. II.):—"Perhaps this may suit you. The edges of side-rails are rounded, and must be 4 in. longer than screen—2 in. at top and 2 in. at bottom. These ends are reduced to form a nice dowel, the use of which will be presently seen. Now take a round rod same thickness as frame, and the same length, on opposite sides; make a nice hollow all its length, so that the rounded edges of frame will fit in nicely. You now want four round pieces each 2 in. long, and same thickness, with a hole bored right through to fit nicely on the dowels of frame. Fix two of these at bottom of centre rod in the hollows, one on each side; take the leaves of your screen, and drop the dowels into the holes; now take the other pieces with holes in them, and drop them over dowels at top; glue, and fix in hollows; and there you are with a hinge that will fold both ways, and show no opening. I may say that it is not necessary to have the sides of frame round, provided the edges are made so, and a piece of bamboo will do well for the tubes."

**Window-Cleaning Chemicals.**—H. B. S. writes, in reply to C. T. (*Ashton-under-Lyne*) (see page 634, Vol. II.):—"The composition of window-cleaning liquid is dilute hydrofluoric acid. The cleaner mixes a little of the strong acid with water in a pail, rubs it on the windows, and quickly washes it off again; if left on the windows, it quickly etches them—*i.e.*, renders them dull and opaque. It cannot be kept in a glass bottle, as it dissolves glass, but is sold in gutta-percha bottles. It must be carefully used, as it causes very bad sores if spilt on the hands; it rapidly clears away grease and dirt from factory windows, and that is what it is used for. I believe there is a Window Cleaning Co. in Leeds who hold a patent for the use of it for that purpose, but I may be mistaken."

**Rods for Plate Rack.**—F. S. (*Highbury*) writes, in reply to J. N. (*Erith*) (see page 812, Vol. II.):—"Rods from ½ in. up to 1½ in. may be bought at any timber yard that stock Swedish mouldings. Stuarts', Drayton Park, Holloway, supply them at 2s. 6d. per 100 feet, ½ in. thick."

**Violin Book and Tools.**—J. H. W. (*Leeds*) writes, in reply to J. E. (*Chatham*) (see page 814, Vol. II.):—"I can, as the result of practical experience, recommend 'The Violin as it was and is,' published by Ward & Lock. With regard to tools, I shall in a few weeks be in a position to supply the same at a reasonable rate, and shall then advertise them in WORK."

**Window Steaming.**—J. (*Portsmouth*) writes, in reply to the inquiry by J. B. (*Colchester*) (see page 670, Vol. II.):—"Nothing will cure this like ventilation, and I would suggest J. B.'s carrying a flue, if possible, directly from over gas jets, as in the improved sun-burners, into a chimney flue—not directly outside, as in this latter case it is almost certain to produce an in-draught. There is generally a spare chimney flue over most shops, the precaution being first taken that there is an up-draught in the chimney. If this does not quite cure it, a few holes in addition may be cut in bottom of window, and covered with fine gauze to keep out dust, thus forming a current of cool air across inside of glass. Will H. Hinge allow me to thank him for his very clear description of Ottoman couch? so plain, that I think the most of us amateurs can understand it. My better-half intends me to have a good try at it, as soon as I have time to spare. Can he suggest any style of hinge, to enable it to be opened from either side? A strong pin firmly screwed on to each corner, and dropping into a metal V bearing, or something of that sort."

**Rods for Plate Rack.**—F. H. (*Streatham*) writes, in reply to J. N. (*Erith*) (see page 812, Vol. II.):—"Joseph Sandell & Co., 101, Waterloo Bridge Road, or any moulding merchant will supply J. N. with ¾ in., ½ in., ⅜ in., and ¾ in. round moulding for plate racks. They are made in lengths from 6 feet to 20 feet. J. N. will find, by getting the rods from a moulding merchant, that he will save himself a lot of trouble."

### V.—Brief Acknowledgments.

## MY HALL STAND, AND HOW IT IS MADE.

BY DAVID DENNING.

INTRODUCTION—MEASUREMENTS—CONSTRUCTION—WORKING DRAWING—MATERIALS—UPRIGHTS—CROSS RAILS—BEADINGS—TURNING AND MOULDING ON COLUMNS—MOULDING UNDER DRAWER—DRAWER BOX—BASE—PANS FOR UMBRELLAS—PANELS—BRASS WORK.

As the entrance hall of a house is the first part of the interior which is seen on opening the door, it is only natural that anyone who takes a pride in his surroundings should wish for a favourable impression to be created in the mind of the visitor by its contents. Unless the hall is of unusually large dimensions, the amount of furniture which can be placed in it is naturally very limited, and for all practical purposes may be said to be confined to the hat and umbrella stand, or, as it is often called, the hall stand. The hat stand may be separate from the umbrella stand, but when space allows, a much more important-looking piece of furniture results if the two are combined. It cannot be said that the stand which I have called "mine" presents any very novel features, either in its construction or its design. It is nothing but a good, substantial thing, not ugly, nor yet devoid of some pretensions to decorative effect. Probably it will be none the less welcome to readers because it, to some extent, follows the traditionary shape and arrangement of an ordinary hall stand, instead of consisting of various ingenious combinations or extraordinary lines. The construction is not difficult, nor need the cost be great, as there is no elaborate carving nor anything which an ordinarily skilful cabinet-maker cannot manage with his usual tools.

As the beginner would hardly attempt to make such a piece of furniture, it will be unnecessary to enter into a minute description of the details of construction so far as the manipulation of the wood and tools are concerned; while the accompanying illustrations almost supply the practised cabinet-maker with all the information he can require. To leave him without any description—or perhaps I should rather say without any hints—to guide him would not be altogether satisfactory to the majority, and the following remarks will, no doubt, be an assistance.

Fig. 1 gives the front and Fig. 2 the end elevation. As both of them are drawn to inch scale as nearly as possible, it will be seen that the outside measurements are as follows: height, 7 ft. 6 in.; width across front, 4 ft.; and depth from back to front, 1 ft. 2 in. It will thus be noticed that the stand is not a small one, although it is not unwieldy or cumbersome. Those who, for any reason, wish to make a smaller stand of similar design will have no difficulty in doing so, as it will only be necessary to take the design as it stands, and reduce the distances between the upright pieces. At the same time, it should be remembered that a very light small hall stand is not generally satisfactory, from its liability to fall forward when heavy coats are hung on it.

Leaving generalities, let us now examine the construction more in detail. We find all the essentials of a hall stand. There is a good-sized looking-glass, so arranged that a person of ordinary height can make use of it without stooping or standing on tiptoe. There is also a convenient table with drawer, and the spaces for umbrellas, sticks, etc., are large and get-at-able. The whole is sufficiently heavy to prevent the slightest risk of a mishap in the shape of an upset from any number of coats or other things which can reasonably be hung on it.

Although general measurements are given, the maker must on no account omit to prepare a full-sized working drawing from which to set out his stuff—as wood is generally spoken of among cabinet-makers.

American walnut is the wood of which the stand from which this description is taken is made, and it looks very well; there is, however, no reason why those who prefer oak or mahogany should not use them. In case oak be chosen, it may be well to say that it should not be fumigated and wax-polished, as the polish is easily injured by damp; and it is unreasonable to suppose that such a piece of furniture as a hall stand can always be kept clear of wet coats and umbrellas.

The uprights are of 1½ in. stuff, so that "down"—which, for the information of novices, may be explained as meaning finished after planing—they are about 1¼ in. thick. This may strike some who are accustomed to see that many London-made, and possibly other hall stands, are made much thicker, as being very thin when compared with these. It must be remembered that the wood to which reference is being made is solid, whereas in the unusually massive-looking stands the parts are generally found to be simply faced on the fronts and veneered on the edges. Of course, if the maker wishes he may go to the expense of thicker wood in the solid, or use facing with pine backing.

The cross-rails are, of course, the same thickness as the uprights. Those at the top, both in the centre and sides, are about 1½ in. wide, while those lower down are about 4 in. The bottom rail, to which the bottom of the stand is fastened, may be of any convenient width, and it is a matter of opinion whether it should project above the bottom board, and so form a small backguard, as in the illustration, or be below the bottom board. In the latter case it may as well be made of pine, as it is not seen.

It will be noted that the two longer uprights are fitted to the bottom rail, the ends of which are fitted to the end pieces. All the other rails are stopped by the uprights, for it would not be good construction for the rails to go right across and the uprights to be fitted into them. Whether the joints be dowelled or mortised and tenoned, is a matter of little consequence. The professional cabinet-maker will probably prefer the former, leaving the other and more tedious one to the amateur. It should be remembered that the centre rail below the glass must be considerably wider than any of the others, as it forms a back to the drawer box.

It will be noted that the edges of the narrower rails are beaded, and that the intermediate wider ones have beads run across them. These, of course, must be prepared before the rails are fastened in. The beadings are shown by Figs. 3 and 4, the latter of which, it may be stated here, is the same as on the drawer front, and the former as on the rails above the spindles in front and at the ends. These rails are of 1½ in. stuff, and about 2 in. wide.

The turning on the front columns, which are of 2½ in. square stuff, is shown full size, so far as the members are concerned, in Fig. 5. As the pattern is repeated for the lower part, only half the length is given. The squares of the columns are ornamented on the front and end, as represented in transverse section by Fig. 6, which gives the parts full-sized.

The moulding on the edge of the rail under the drawer is given in Fig. 7, but this—and, indeed, any of the others—may be altered to suit the fancy of the maker, who, very likely, may have preferences of his own.

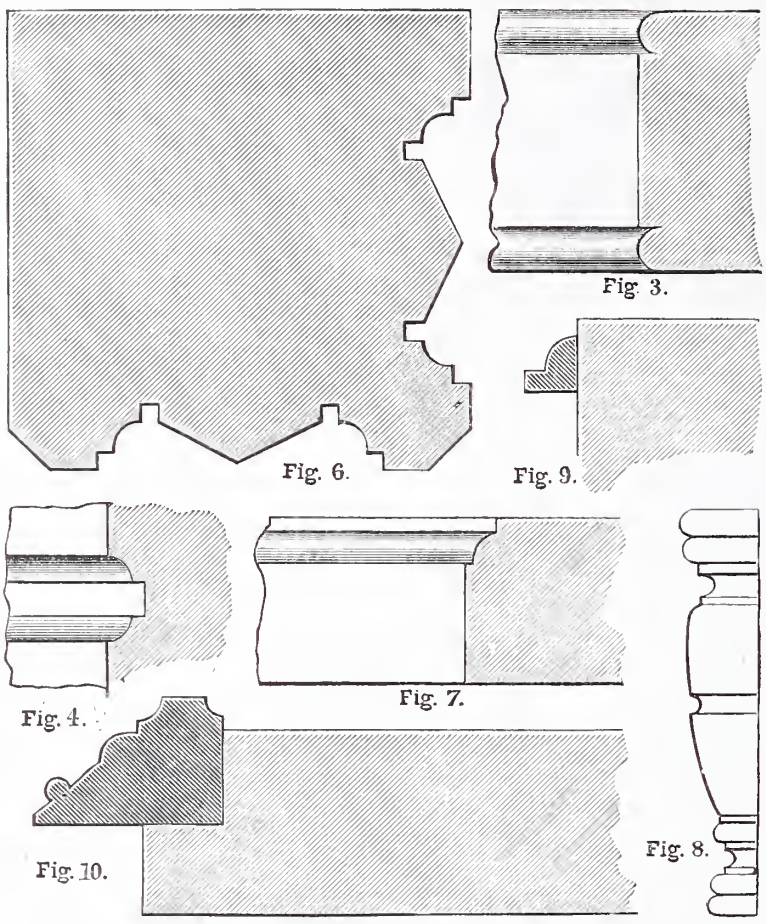

Fig. 3.—Beading on Rails. Fig. 4.—Beading on Drawer Front. Fig. 6.—Section of Square of Column. Fig. 7.—Moulding on Rail below Drawer. Fig. 8.—Turned Spindle. Fig. 9.—Panel Moulding. Fig. 10.—Moulding for Glass. All Figs. full size.

The same pattern of moulding is on the edge of the table top, which is screwed through from the back.

The ends of the drawer box are solid 1 in. stuff, and are fastened in the same manner to the back. Their bottom edges are on a level with the lower surface of the rail, under the drawer front. As the drawer and its fittings present no unusual feature, it may be presumed that it is unnecessary to say anything more about them. The fitting of the ornamental rail beneath presents no difficulty, and its shape is sufficiently shown in Fig. 1 to enable anyone to set it out.

The base will require some thought to be given it by those who are not familiar with similar constructions, though it is very simple. The front rail—viz., that which is visible in Fig. 1—is about 4 in. wide, of 1 in. stuff. The back one has already been referred to, so need not be mentioned further. As is well known, pans or tins are usually let into the bottom of umbrella stands, and this one is no exception to the general rule. They are, of course, where they will be most convenient, and that is under the open spaces on each side of the drawer. The whole of the bottom may be covered in, and holes subsequently be cut for the reception of the pans, but it is more convenient to have these of a good size than to have them so small as they sometimes are in stands otherwise well got up. The pans in this stand are, therefore, as big as they could be without being unsightly. They fill the space from back to front, and are practically square. Their edges rest on the front rail, on a ledge fastened to the back one, on the end rails, and on the board which encloses the remainder of the bottom. Now, the only part which is likely to trouble anyone is the end rail, for unless made as thick as the front columns, there will be a hitch somewhere, as the maker will soon find out for himself unless he is careful. To use such a piece as supposed would be only a waste of good material, so the way to do without it is to make the end rails say 1 in. less in depth than the front one, and then to make them equal to this by planting a piece of the necessary width on the top of them. The same object might be attained by making front and ends of the same width, and setting them back as far as possible. This method, however, would not look so well. In case anyone may want a pattern of the small spindles to turn to, Fig. 8 gives in full size all that is necessary.

The construction has now been sufficiently described, and all the rest to be done may be looked on as ornamentation, if we except the hooks, which, of course, are a necessity on any hall stand.

The lower panels above the umbrella spaces are plain, with sunk bevels. They are fastened in by mouldings of the pattern shown by Fig. 9, which gives the full-sized section. The same is used to the panels above, which are simply pieces of $\frac{1}{2}$ in. stuff, shaped as shown by the bow or fret saw. The carving on the panel above the glass and elsewhere is of the simplest kind. The moulding round the glass, as befits the most conspicuous part of the stand, is of a more elaborate character than the others. It is shown, also in full size, by Fig. 10. The fitting of the silvered plate calls for no special mention. Those who do not mind the trifling extra cost should have its edges bevelled.

The brass work consists of four coat hooks, two hat and coat hooks combined, and four single hat pegs, as well as a handle for the drawer.

We now come to an end of the hints for the construction of a combined hat, coat, and umbrella stand, with hall table, and if any beginner does not find them ample enough, let him remember that the job is not a suitable one for a novice, and that by the time he has acquired the manual skill necessary to make it, he will find that difficulties in the way of understanding the construction have vanished.

## A USEFUL MICROSCOPE LAMP.

BY H. B. S.

Advantages of Lamp — Method of Making Lamp Chimney of Tin Plate—Method of Making Shade—Cost of Lamp, Chimney, and Shade.

For the benefit of readers of Work who have a microscope, I will here describe a lamp and method of making which will, if followed, for a very small sum supply them with a useful article which would cost at least 15s. if bought of a dealer.

The fully-made article is seen in Fig. 1. The advantages of the lamp are: (1) That instead of the ordinary lamp chimney, a chimney of tin plate is substituted, in which is an ordinary 3 in. by 1 in. glass slip, or a slip of tinted glass of the same size; (2) the glass slip can easily be replaced, costing 4d. per dozen; (3) the glass slips do not break so easily with the heat as the glass chimneys; (4) the lamp is so low that, by tilting the microscope a little, direct light may be got from the lamp without reflecting the light by mirror.

Buy the lamp body—they cost 6½d. in Liverpool. The wick stands about 3 in. from table. Then get a piece of tin plate, 6 in. by 5½ in. (Fig. 2), and mark out an oblong by means of rule and steel point, commencing $\frac{3}{8}$ in. from side, of 2½ in. by 1¼ in., then, by means of a cutting chisel, cut the piece out. Next prepare a strip of tin, $7\frac{3}{8}$ in. by 1 in. (Fig. 3). Rule right across it four lines, at 1⅝ in., then at 2½ in. from last, then at 1⅛ in., and again at 2½ in. Then rule right along one edge ¼ in. from side, and on the other side ⅛ in. and at ¼ in., as shown. Bend the box into shape, after snipping at each of marks ¼ in. on each side. This will leave ⅛ in. over at end, which requires soldering. Snip the box at top and bottom as shown (Fig. 3), so that the box will accommodate itself to the round shade. When this is done, push the box through hole in large sheet, bend up the ¼ in. as a flange, bore two holes on each side of the box through both sheet and flange, and rivet with copper rivets. Now bend the sheet on a round article, allowing about ¼ in. to wrap over, bore holes and rivet. The chimney will now be 1¾ in. in diameter, which will suit most lamps.

It will be found that the box will be thrown a little out of shape by bending the chimney into the round form, but this can easily be remedied by a few touches of the pliers. Now bend the top piece outwards ¼ in. as marked, the bottom piece outwards ¼ in., then inwards again for ⅛ in., and the side pieces ⅛ in. inwards, as shown in Fig 4. The box will then appear as in Fig. 4, and will allow of the glass slipping in from above, being held there by the side flanges.

All that remains is the making of the shade. This shade prevents the light of the lamp coming to the unoccupied eye. Cut out a piece of tin plate, 4⅛ in. by 1¼ in., cut as in Fig. 5; this will allow 1⅛ in. for top and 1½ in. for each side. Snip at each mark to ¼ in., then bend into shape, and bend inwards each of the pieces snipped ¼ in.; this will then allow the shade to rest on glass slip, as shown in Fig. 1. The tin shade, being bright, is a good reflector, and a great deal of the light lost in every direction with glass chimney is now reflected and sent out in one direction; besides this, by using direct light from the lamp, a good light is got for high powers or for rather opaque objects.

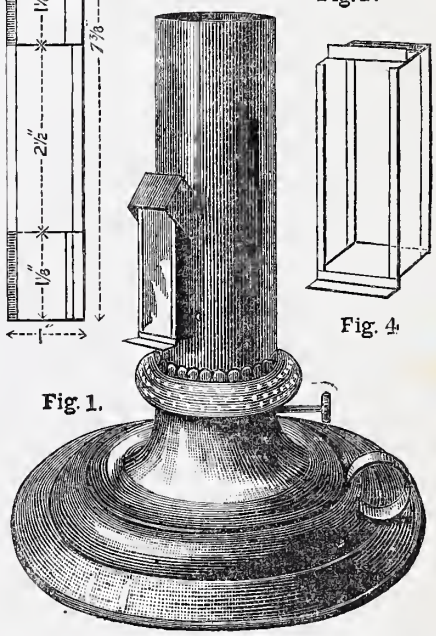

Fig. 1.

Fig. 1.—Microscope Lamp complete. Fig. 2.—Tin Plate to fit over Lamp Glass. Fig. 3.—Pattern of Template for Box. Fig. 4.—Box when bent into Shape. Fig. 5.—Hood or Shade for Box.

My lamp cost me (without tools): For lamp body, 6½d.; for one sheet double-crown tin plate, 5d.; copper rivets, 2d. (per oz.); one glass slip, ⅓d. Total, 1s. 1½d. and ⅓d. The glass slip has lasted quite a year, and is now as good as new. There are two friends of mine who have also made them, and they are as well pleased with their lamps as I am with mine. Finding this to be the case, it has occurred to me that others may find the lamp thus fitted and adapted for the purpose equally useful, and I have therefore placed on record in Work the result of the experiences of myself and my friends, and the way in which we went to work; trusting that it may encourage and enable others to follow in the same path.

# CONSTRUCTIVE STRENGTH IN METAL WORK.

BY J. WHITFIELD HARLAND.

MODES OF UNITING METALS—TENSILE AND COHESIVE STRENGTH—MANIPULATION OF IRON—PREPARATION OF STEEL—EXPANSION AND CONTRACTION OF METALS—ROLLING AND HAMMERING IRON PLATES—CONDUCTION OF ELECTRICITY IN WOOD AND METAL—ELASTICITY.

IN my hints in No. 76, Vol. II. of WORK, on "Constructive Strength in Woodwork," I pointed out that the very nature of wood itself demanded that the way of the grain, and the splitting tendency of it, should be taken into account.

In Metal Work there is no grain such as exists in wood, and metal does not split, but it cannot be held together by cement as wood is by glue; and whilst wood cannot be melted or heated, metals can be, and this gives rise to a totally different mode of construction.

Uniting metals may be done, firstly, by welding: *i.e.*, by heating almost to fusion two parts, and hammering them until they form one piece; secondly, by riveting; thirdly, by screwing or bolting; fourthly, by brazing or soldering; whilst the shape or form of pieces of metal may be altered, firstly, by forging; secondly, by stamping; thirdly, by melting and casting; fourthly, by rolling or bending.

In all construction, then, we must consider the reason for preferring one of these modes in any given case—that is, we must find out which of them is the strongest in relation to the purpose in view, and a few hints (for I only consider these papers as hints, and anything but an exhaustive treatise) in this direction may help WORK readers to think out for themselves, in their own way, and apply to their own work, such hints as may seem to them to have some bearing on the particular job.

Metals, like woods, have each their own tensile and cohesive strengths, as well as resistance to compression, from which their breaking strain can be ascertained. Tables are published of these strengths, and in construction, such as buildings, bridges, ships, etc., it is no longer safe to work merely as is done in carpenters', joiners', and cabinet work, with a knowledge of *where* strength is required; we must measure and estimate not only where strength is wanted, but how much strength is necessary. Human life is at stake in such work, and an error of judgment or a false calculation might produce a catastrophe causing agony and death to scores of people, besides making their relatives and survivors wretched, and often pauperising them. Such heavy responsibility as this should not be lightly undertaken, and demands the most conscientious care in design, in calculation and watchfulness, during its gradual completion, that no bad workmanship or faulty material creeps in to become a menacing danger.

By far the most useful and most used metal is iron, and it is of three distinct varieties—cast-iron, wrought-iron, and steel—which are none of them chemically pure, but are pure iron differently impregnated with carbon and other bodies. Thus cast iron contains the most carbon, steel less, and wrought-iron less still. By various processes cast-iron may be deprived of nearly all its carbon, and then becomes malleable or wrought-iron, or wrought-iron can be changed into steel by processes which add carbon to it: if too much carbon be not added, its malleability is not only not impaired, but improved, whilst if more than sufficient carbon be added its malleability is quite destroyed, and it becomes brittle, is much weakened in both tensile and cohesive strength, although its resistance to compression is not vitiated to the same proportionate extent. There is also a comparative degree of hardness in these three forms of the metal iron, owing to the presence, no doubt, of carbon. Cast-iron, whilst homogeneous, is granular in texture—I was about to say crystalline. Steel also is so to a less extent, partaking more of the fibrous structure of wrought-iron, though in an inferior degree; but it also possesses the property of being capable of excessive hardening, or tempering, as it is called: a property without which no tools for work could ever be made, and which all workers ought to regard as one of God's best gifts to man. Curiously, cast-iron with more carbon, and wrought-iron with far less, do not possess this property, except so far as their outer surfaces are concerned, which is termed, therefore, case-hardening. An instance of case-hardening is afforded by the Bower-Barff process, as it is termed, which consists in exposing cast-iron, wrought-iron, and even steel heated to redness to the action of steam (*i.e.*, the vapour of water). The effect of this is to convert to a slight depth the surface exposed into an oxide of iron, viz., the black or magnetic oxide (or peroxide of iron $Fe_3O_4$) which occurs also in a natural state, and is almost as hard as the diamond, and crystallises in cubes. It is useful, also, inasmuch as, being a higher oxide than the protoxide (*i.e.*, iron rust), iron so treated becomes rustless, resists the weaker acids and weak solutions of the stronger acids; thus it requires no painting, and is practically indestructible. It is called magnetic oxide, from the fact that natural loadstones consist of it. Cast-iron, if quickly cooled, especially in damp sand, where the heat of the metal when poured converts the moisture into steam, is almost converted in parts of its surface into this oxide (or perhaps, also, a silicate or aluminate combined with it), and the "skin," as it is termed, is extremely hard and brittle; but if the castings be annealed—that is, cooled very gradually—they are termed "malleable castings"—are fibrous rather than crystalline, and will bend rather than break.

Further, steel prepared by adding carbon to wrought-iron—especially when it has been subjected to a great deal of hammering, and more so still if made of wire, nails, or other small pieces welded into one mass—is far superior to steel made by partially burning, or otherwise getting rid of the excess of carbon in cast-iron. In other words, adding carbon to wrought-iron is better than taking carbon away from cast metal or "pig-iron." Bessemer steel partakes of the character of the latter process; Swedish steel of the former. Its tempering property is still further developed and improved by hammering—hence the best tools are those upon which the most labour has been expended, and therefore they are cheaper in the long run than low-priced ones. In a less degree, rolling adds to the value of both steel and wrought-iron—its action making both more fibrous, and therefore tougher.

In generalising thus, as I am doing, I must not omit to mention the fact that heated iron, steel, and cast-iron contract in cooling, although not to the same degree, probably, because the heat employed is much greater in the case of cast-iron than in forging—its contraction is greater. Steel also may be melted and cast, and then its contraction is also greater than forged or hammered steel. In order to obviate this contraction, which is unequal and by no means uniform, since it depends upon the rapidity of cooling in one direction being hastened or retarded by surrounding influences, Sir Joseph Whitworth successfully introduced the process of casting under compression, whereby the melted metal was compressed whilst heated to the extent required to prevent any further contraction as it cooled. Patterns, therefore, were made the exact size, instead of any allowance for contraction being made. That compression castings are immensely stronger than ordinary castings almost goes without saying, but if proof be needed, take a strap pulley or drum. The boss scarcely contracts at all—the arms, in proportion to their length, only about $\frac{3}{16}$ths of an inch to the foot; whilst the thin flat rim, six times the length of the arm, still contracts $\frac{3}{16}$ths of an inch to the foot. It stands to reason that there will always be a compressive strain upon the arms, due to the rim having contracted six times as much as the arm has done. But under compression the contraction is not in cooling, but whilst the metal is in a molten state, when its component particles are mobile, and can seek their own positions. How often, in turning drums or pulleys true on the face, do they break and fly to pieces—directly the "skin" is turned off, the rebound, so to speak, of the compressive strain on the arms overcomes the cohesion of the rim, and it gives way. Here let me remark that from its form the rim of a pulley will stand a far greater force from without than from within; a pipe, therefore, will burst from within far more easily than be crushed by pressure from without; nay, more, it is almost, not quite, as capable of resisting crushing from without as if it were solid throughout; and the crushing strain, if applied endwise, therefore, is practically the same as if it were solid, thus a hollow column will, if of correct proportions, bear as much weight as a solid column would—more, in fact, than the same weight of metal could sustain if made solid instead of tubular. This is due to the distribution of contending forces, whereby they neutralise each other's action. Hence we may safely deduce that form or shape contributes to the strength (as it also does to beauty, if thoughtfully used) of construction in metal. Take as a case in point a plate of iron $\frac{1}{4}$ in. thick, 3 in. wide, and 7 feet long. Support the extreme ends, and put on in the middle weight enough to break it. But if you dish such a plate—that is, form a corrugation lengthwise, say $\frac{1}{4}$ of an inch in depth—although the plate will be narrower, twice the previous breaking weight will be supported without danger. To consider the torsal or twisting strain: if the plate be flat, a very slight force applied in a contrary direction at each end will twist it easily; but if it be dished as described, such slight amount of force will have but little effect; it would remain practically rigid. In like manner, angle iron is almost as strong as a solid bar of the same breadth and depth, and far stronger than the same weight of iron rolled into a square or round bar; whilst T iron is for some positions, and under certain strains, stronger still. There is a still further gain: the weight of superincumbent iron is so much less for the same equivalent of resistance to strains—as in a roof, for instance—that the supporting walls or columns having less to carry may be so much, proportionally, weaker—hence an economy of material—without loss of

strength, whilst the labour in hoisting a less weight to the same height is also lessened. Further, if instead of *rolling* iron to such sections as I have alluded to, it were *hammered*, its strength would again be increased. The true explanation of these phenomenal facts lies in the great truth that all metals resist compressive strains much more easily than they do tensile, torsile, or side strains—just as I said there was a first principle in considering constructive strength in woodwork, but under different conditions. To illustrate this familiarly, a man can carry on his back or shoulders a far greater weight, when once it is raised for him, than he can lift from the ground.

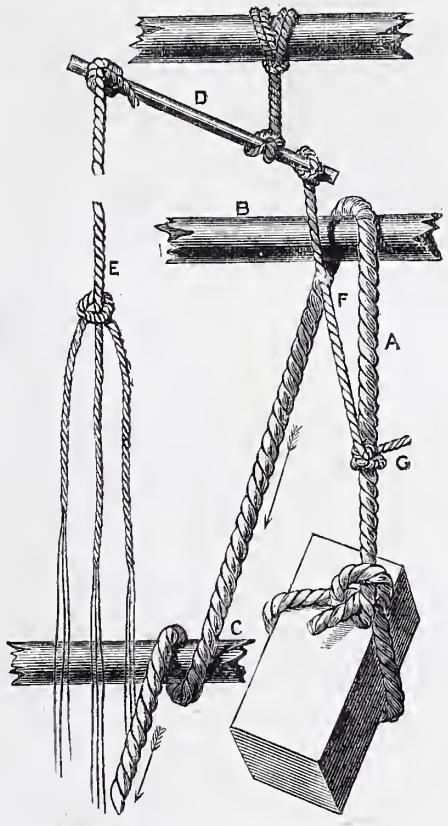
I ought not to omit another point of difference between wood and metal, and it is a very important difference—viz., that whilst wood never contracts in length, all metals do under the variations of temperature. Wood is affected not by mere temperature, but by moisture and light. Metal is, so far as is at present known, affected by heat alone. Light and damp apparently, though this is not proved, have no influence on its expansion or contraction, which probably is due to its greater density, or its homogeneous, instead of cellular, structure, which leaves no interstices for moisture to lodge in or light to permeate.

Another point of difference, which I fear has not been at all sufficiently investigated, but which offers a wide field for speculative scientists, is the different degrees of comparative conduction of electricity in wood and metal. We do know that cast or wrought-iron girders on railways when laid horizontally to carry traffic become less and less fibrous, and ultimately crystallise. Is this due to electricity, as I more than suspect, or to vibration, as some engineers maintain? Does vibration act direct, or does it, in some unknown and incomprehensible manner, generate or attract electricity? I cannot say, but I trust some day it may be elucidated. As in girder bridges, without such knowledge we cannot find any means of negativing its effect, because we do not know the cause. Take girders in subways, etc., for instance: if girders give way from this cause—*i.e.*, crystallisation—or from the constant action of rust, enhanced by sulphurous fumes emitted by locomotive engines and bad ventilation, "What price for shares?" Were I at the elbows of railway engineers, I would suggest that in replacing any girders the new ones should be previously made *rustless* by the Bower-Barff process, and that experiments be made, at no matter what cost, to determine what is the cause of crystallisation, and what is its remedy; and that a thorough inspection of all girders should at once be made on all the underground routes in the country. Unless this be done, no one will be less surprised than I to see an "extra special" newspaper detailing some catastrophe directly attributable to this cause.

There is one point of similarity between wood and metal that ought not to be lost sight of—viz., elasticity, a quality or attribute of both, differing only in degree. In some woods it is, as in some metals, nearly absent, as in lead and in cocoanut, where the elasticity is that of ivory, mere resilience, when struck. Steel, as a metal, possesses this attribute in the highest degree, as do lancewood, and yew, and hickory among woods. In metals, the greater the ductility the less the elasticity; and the reverse also holds good. Gold, the most ductile of metals next to lead, is absolutely inelastic. Now, elasticity is a force!

The subject of constructive strength in metal work after this introduction will divide itself into two distinct classifications—the one involving strength obtained by form only, and the other involving strength obtained by, in addition, utilising separate parts which, in the aggregate, being constructed on the lines of the first classification, and united in some one of the foregoing methods, shall, as a whole, constitute good construction.

It will be impossible in this connection to refer to such minor considerations as the way to put together jewellery, for instance, where appearance is the main consideration. I shall devote my limited space, in the two papers to follow, to illustrating "good form" and good combination for strength, rather than beauty.



Chinese Method of raising a Heavy Weight.

## A CHINESE METHOD OF RAISING A HEAVY WEIGHT.

BY P. B. H.

The annexed sketch illustrates the method at present in use in China for raising heavy weights in the construction of buildings, etc. Whether any readers of Work will ever be brought into such a predicament as to have recourse to a similar method, time alone will show. It will, no doubt, be interesting, however, as an illustration of the antipathy this people has to anything new. Their method of procedure is as follows:—A good stout rope A is fastened round the object to be raised (in this case a stone is shown), and carried over a horizontal beam B, placed at some convenient height above the permanent resting place of the stone; it is then given a complete turn round a lower one C, and the end is dropped to the ground or some convenient platform, where it is held fast by one or more men, as required. This rope is principally for holding the weight after each rise, while the knot G is being readjusted. At a convenient height a lever D, about 25 ft. long, is hung suspended from a beam by a rope, which acts as a fulcrum about 4 ft. from the end. From the shorter end of the lever a rope is dropped and fastened by a running knot as low as possible on the main rope A. Another rope E at the longer end of lever falls to some convenient stage, where the end being unwound, as shown, each separate strand is grasped by one or several men, according to the power to be exerted. The ends of the rope E are now pulled, and the rope A is then raised, together with the weight, by the lever D, the men at the bottom end of A taking up any slack during the raising. This process is continually repeated, the running knot G being lowered, and the whole raised until the weight is at its destined height.

The above is a very good example of the use of the lever and friction, as very little force will be required at the lower end of the rope A to keep a heavy weight suspended, on account of the friction between the encircling rope and the beam C. This same frictional action is often seen when bringing up steamers at the landing-stage, and also on the rotating capstans used for shunting in railway sheds.

When we consider that such primitive means are still in use among the Chinese, who can be surprised that it is extremely hard to induce them to adopt railways?

There is thus, it will be seen, plenty of latitude for the persuasive powers of engineers and commercial travellers to induce them to use steam and machinery; but labour being no doubt so cheap, and the saying that "Time is money" not having yet been transplanted to the Chinese brain, there will be still some obstacles to overcome their prejudice. They are much worse than the natives of India in having anything instilled into them. These latter, when first the barrow was introduced, filled it about a quarter full, and then carried the whole on their heads. It was some considerable time before its proper use could be driven into them: so that it may still fall to some of our readers with strong persuasive qualities to make them abandon such methods, though I have no doubt the above arrangement would be useful in some parts of the world inaccessible to machinery.

## THE RUBBER IN FRENCH POLISHING: HOW TO USE IT.

BY DAVID DENNING.

How to Make the Rubber—The Outer Covering—The Wadding—Prevention of Creases in Covering—Charging with Polish—Motion of Rubber over Work—Re-charging—Touching with Oil—Preservation of Rubbers.

As is no doubt very well known, the pad by means of which French polish is applied is technically called the rubber. Without it the French polisher can do little or nothing in actual polishing, although he may not require it in the preliminary operations of oiling, staining, etc. However simple in itself the rubber may be, it is necessary that it should be properly and carefully made of suitable materials, for if it is not, really good work cannot be done with it. Possibly some readers who have seen polishers at work may be inclined to think that no great care is necessary, for all they saw was a dirty-looking rag covering a similarly uninviting-looking lump of wadding, or, as it is sometimes called, cotton wool.

Notwithstanding appearances being against it, the rubber, if in competent hands, will, on inquiry, be found to have been more carefully made than might have been expected, and the polisher would, in all probability, prefer it to any nice clean-looking rubber such as a novice would choose. Mind, it is not said that a dirty rubber is what is wanted, for dirt is fatal to really first-class work, and the polisher should keep his rubbers as clean as he possibly can. They naturally will get stained and discoloured with the polish, but that is a very different matter from being dirty. It may be news to some readers that old rubbers are preferable to new ones, provided that they have been properly taken care of and not allowed to get hard. The care of rubbers will be dealt with later on, and, in the meantime, their construction and general manipulation may be attended to.

For the outer covering or casing of the pad, soft rags are necessary. They may be either cotton or linen, the great point to be observed as essential to success being that they are perfectly soft. It should, perhaps, also be said that they must be tolerably fine, or, at any rate, free from knots or lumps. From this it will be seen that though rags have been mentioned as suitable, some care in their selection is necessary, and that it would never do to have a piece with a seam across it for a rubber, as anything which would tend to scratch the film of polish as it is being laid or worked on in the final operation of spiriting off must be carefully avoided. Some polishers advise the exclusive use of linen, but to confine oneself to this is a needless restriction. It must not be supposed, because rags have been mentioned, that new material may not be used. To render it suitable, however, it must be thoroughly washed to remove all traces of the sizing and stiffening with which it may have been finished. Of course, before it can be used for polishing it must be thoroughly well dried. This may seem a small point to urge, but it must be remembered that success in polishing depends to a great extent on the observance of details, and judging by the answers in the "Shop" columns, difficulties which would not occur to the experienced polisher are constantly cropping up. The necessity of avoiding damp (aqueous) cannot be too much insisted on. In addition to rags—of which not a very large quantity need be laid in, as in an ordinary household there is generally plenty of material available—some wadding will be required. This really is the rubber, as the rag is principally of use as a covering and to keep the wadding within proper bounds. White wadding is the best to use, and it is readily obtainable from any upholsterer or chemist; possibly it may be purer if got from the latter, and it is most certainly very much dearer than any reasonable upholsterer would charge for something equally suitable. Enough ought to be obtainable for a few pence to last a considerable time. If got from an upholsterer the wadding is sure to have a thin film or skin on one or both sides, according to whether it has been split or not. Anyhow, this skin must be removed, leaving nothing but the soft cotton. In cotton manufacturing districts, it may be useful to know that the raw material, if it is clean, will do equally as well as the finest wadding. The material known as cotton flock, and used by upholsterers as a stuffing for mattresses, chairs, etc., is not suitable, unless perhaps for the coarsest work. Even then it should not be used if anything better is available. For some special kinds of work rubbers composed entirely of flannel are occasionally recommended. It is, however, a matter of personal preference, and it is, to say the least, very doubtful if there is any advantage in using flannel, except sometimes, perhaps, for large flat surfaces, which can be got over more quickly with a large rubber than with a small one. All things considered, the novice cannot be advised to use any but the wadding rubber, and to become a competent polisher with it before experimenting with anything else.

To form a rubber it is only necessary to take a piece of the wadding and a piece of rag of sufficient size to enclose it. It is not enough, however, merely to wrap the wadding up anyhow, for it is absolutely necessary that on the bottom or sole of the rubber—*viz.*, that part of it which comes in contact with the work—there shall be no creases or folds. If there are any, then the delicate shellac film will be scratched. Perhaps the best way to convey the idea of what is wanted in a good rubber will be to imagine the wadding and rag ready to hand. Let a piece of the wadding be taken—say sufficient to form a ball, when moderately compressed, of double the size of a walnut. Put it in the centre of a piece of rag and gather up the edges of this so that the wadding is enclosed, as it were, in a bag. Keep the bag from opening by holding it with the thumb and finger tips, then press it down on any flat surface to flatten it, when, provided there are no creases, the rubber may be regarded as perfect. The whole thing is really very simple, and with a little care it will be almost impossible to make a mistake. The size of the rubber will, to some extent, naturally depend on the nature of the work, but that just given may be regarded as generally suitable. It is, however, impossible to lay down hard-and-fast rules in this respect, and the polisher, as he gains experience, must be guided by circumstances. Too large a rubber is not advisable at first. It has been mentioned incidentally above that the rubber is to be held by the tips of the thumb and fingers, but it must be understood that though this is the usual, because the most convenient, way with a rubber of moderate dimensions, the polisher may adopt any other method which suits him better. He will probably find, for example, that when using a large rubber it can be more conveniently used by holding it in the palm of the hand.

To use the rubber it must, of course, be charged with polish. Some care will have to be exercised in doing this, and to prevent mistakes it is well to say here that actual directions for completely preparing and polishing any article are not now being given. We are at present only concerned with the rubber, so that many points which it would otherwise be necessary to refer to may be disregarded with the assurance that they will be considered in due course. Some polish being handy, the covering of the rubber is to be opened so that a little polish can be dropped on the wadding. A convenient way of doing this is to have the polish in a bottle, the cork of which has a channel or notch cut in it to allow only a few drops at a time to escape. Some polishers dip the rubber, or rather a portion of it, into the polish, but then the novice must remember that an expert may venture on methods which a beginner should not attempt. The method recommended is the one generally adopted, so the learner will be under no disadvantage in following it. The wadding must by no means be saturated with polish, of which only enough should be used to moisten it and come through the rag covering when pressure is applied. The rubber having been charged, gather up the rag as already directed. Then, to equalise the polish, press the rubber moderately firmly into the palm of the other hand. The sole of the rubber ought now to be ready for application to the wood, which, for explanatory purposes, may be assumed to have been properly prepared to receive its first coating of polish. The principal thing at this stage, it must be recollected, is to get a good even body of polish on the wood, not thick in one place and thin in another, but distributed all over alike, and not too thickly anywhere. How this may best be done depends, to a certain extent, on circumstances, and on the custom to which the polisher has become habituated. One example must suffice, as, after all, if the desired result is got, the precise method is of secondary consequence. Let it be assumed that the work to be done is a small table top or other flat surface. With moderate pressure on the rubber, wipe quickly over the entire surface, first with, then across, the grain of the wood. Then proceed without delay to go over it more minutely, the motion generally adopted being shown in the accompanying illustration. The pressure should be gentle at first, but as the polish gets worked in and the

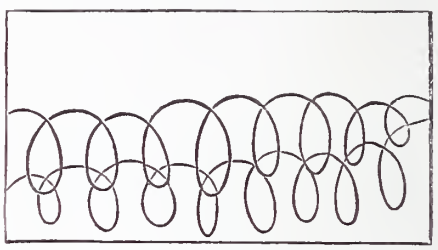


Diagram showing Movement of Rubber in French Polishing.

rubber drier, it is to be increased, though at no time must the pressure degenerate to mere scrubbing.

A very important point which it may be necessary to caution the novice about is the necessity of not allowing the rubber to remain stationary on any part of the work, and on no account ever to leave the rubber lying on it during temporary absence or at the end of the day's work. While the rubber is in contact with the wood it must be kept constantly in motion. As often as the rubber gets dry it must be recharged with polish, but let the novice beware of using this in excess.

When the rubber seems to stick, instead of moving pleasantly and sweetly over the wood, just touch the face of it with a little raw linseed oil. If the oil could be dispensed with altogether it would be better, but as it cannot be, the next best thing is to use it as sparingly as possible. The merest touch will suffice.

When any job is finished do not throw the rubber away, as amateurs have been known to do, under the impression that a rubber, when once laid aside, becomes useless. It does if left exposed to the air, because the spirit evaporates, leaving the shellac to harden. As old rubbers are better than new, when done with they should be kept in an air-tight receptacle; a tin canister or a biscuit box will do as well as anything. If they are laid aside for any length of time, they will even then become hard unless the box be perfectly air tight, which it probably will not be. A few drops of spirit put into the box now and then will, however, keep the contents in proper condition for use.

## WIRE-WORK IN ALL ITS BRANCHES.

BY JAMES SCOTT.

### The Wire Gauge and its Variations.

The gauge is an instrument for determining the numerical size of any particular piece of wire. There are many different kinds of gauges, and, upon good authority, it is said that great variance exists amongst them. Fig. 4 is a drawing of the one I have seen mostly used. The decision, when ascertaining the size, is arrived at by placing the wire in the *notches* (the holes are merely for the sake of convenience), and the number of the notch into which it will exactly fit distinguishes the size by which the wire is recognised.

There is a little book, published by Messrs. Spon & Co., Charing Cross, London, written by Mr. Thomas Hughes, entitled, "The English Wire Gauge"—a book of which my opinion is that it would prove usefully acceptable to wire-drawers and wire-workers alike—in which are given over two dozen diagrams of distinctly different wire gauges, the originals of which, the author tells us, he has been collecting, and are of this and also last century's manufacture. Through the whole of his book he clamours for a standard gauge, on the grounds that at present the same sized notch on two or more different gauges is known by different numbers, thus frequently creating confusion.

I will take the liberty of making a few quotations from his handy little publication. In one part he says: "An order was received by cable from New York for . . . No. 36 W.G. (wire gauge). The receivers gave out the order No. 36 B.W.G. (Birmingham wire gauge), not aware of any other wire gauge. The manufacturers, incidentally learning what the . . . was for, instituted inquiries, and discovering it was for America, rightly concluded the gauge intended was Stub's, or Warrington wire gauge, that being the 'Birmingham wire gauge' commonly used in the United States. Had this order been executed in No. 36 B.W.G., the . . . would have been useless for the purpose intended. No. 36 on Stub's gauge is No. 44 on the 'Birmingham wire gauge,' and the difference in the price of . . . this order £28. . . ."

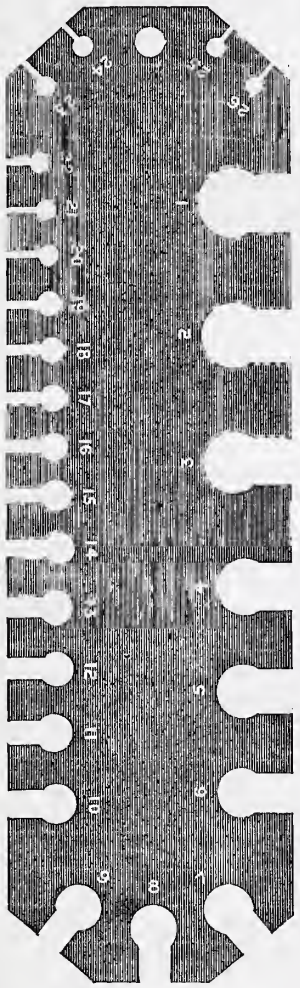

Fig. 4.—The Birmingham Wire Gauge (B.W.G.).

Mr. Hughes gives a drawing of what he proposes should be accepted and used as a "standard English wire gauge."

Although I have recommended his book to wire-drawers, I must tell them that in one portion he says: "Wire-drawers, as a body, are not the most intelligent of workmen; withal, they are too well aware of the fact that wire gauges vary, and are consequently content to draw their wire carelessly, irregular in size and form, knowing disputes cannot be settled by gauges." Whether this is fair or unfair to this section of workmen I will not venture an opinion. I trust it is not, for I have always been inclined to believe that the average British workman, whatsoever he laboureth at, is a painstaking individual. But Mr. Hughes gives his reasons for arriving at the above conclusions; and he also gives a brief but interesting history of wire-drawing.

He elsewhere says: — "Accurately drawn wire is daily becoming more and more incumbent upon manufacturers. Formerly good drawing was wire which would enter one notch, but not the next notch on the gauge to it, the limit of variation—say No. 1 wire—being the two-hundredth part of an inch. It mattered not whether the wire was round or oval." This is, undoubtedly, a fact, but I shall not endeavour to alter such circumstances, and therefore shall adopt the use of the gauge shown in Fig. 4, one which has been extensively used. Whenever I may mention certain sized wire in connection with any of the articles which I shall do my best to describe in following papers, it must be understood that I am using the numbers indicated upon the gauge just spoken of.

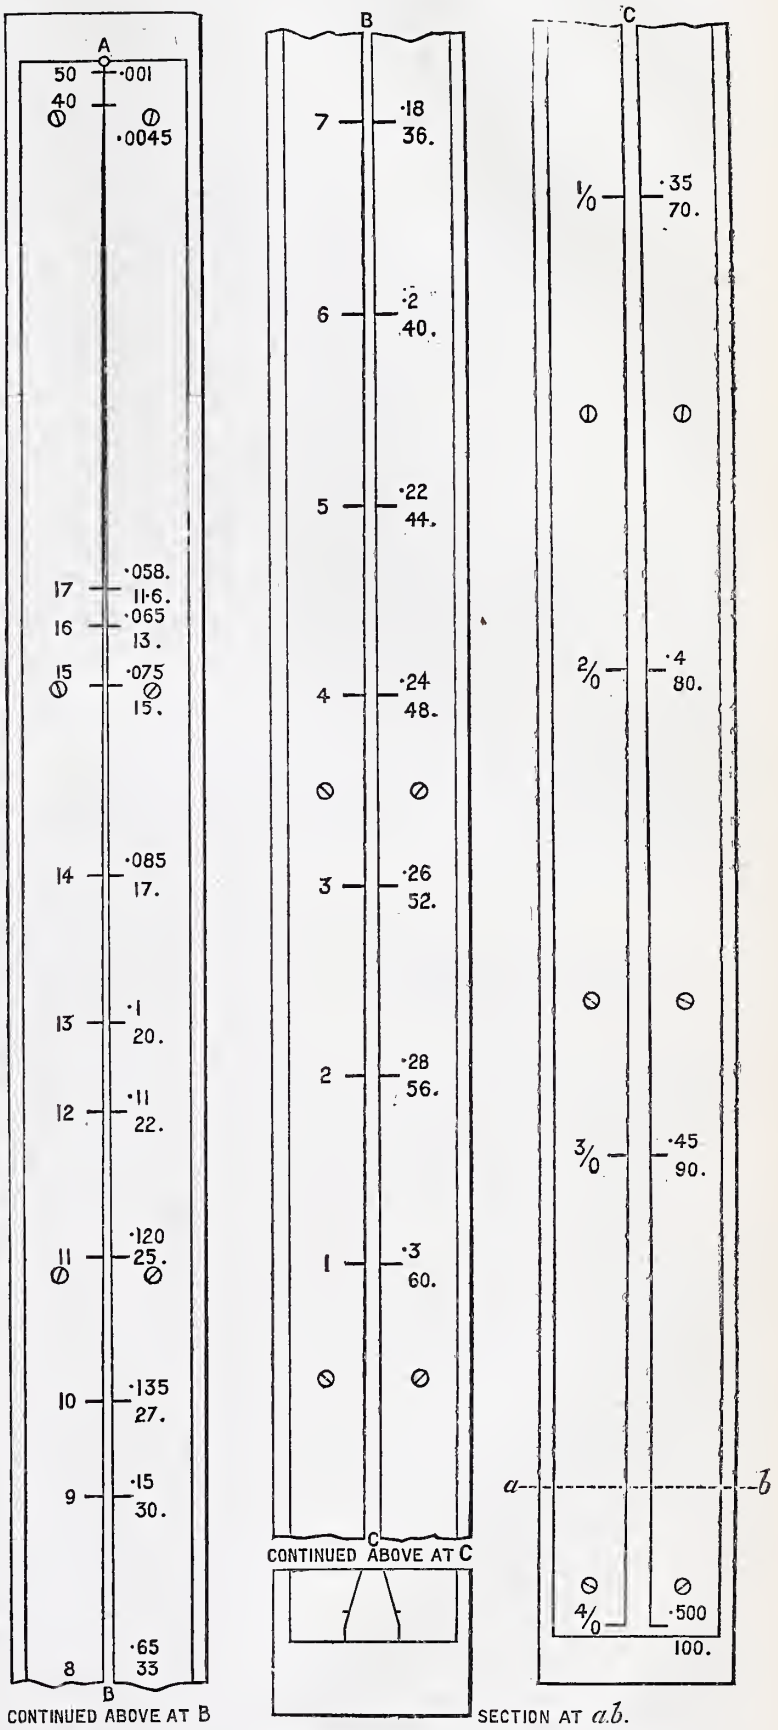

Fig. 4a.—Hughes' "English Standard Wire Gauge," slightly modified.

As wire increases in thickness, it is very often distinguished as *rods;* but it must not be assumed that I have taken any particular thickness as a starting point, for what in one workshop would be merely called wire would in another be termed rods. In reference to this Mr. Hughes says :—

"I have not found a wire gauge made anterior to 1846 to contain a larger size than No. 1, demonstrating that down to 1846 the largest size *wire* was No. 1. Anything larger was called *rods.*"

I have alluded to wire-drawers, but it is not my intention—indeed, it is not within my power—to describe the process of wire-drawing. In fact, such really has no more to do with *wire-work* than the operations carried on in saw-mills have to do with what is generally known as *wood-work.* I give in Fig. 4A a diagram of "the English standard wire gauge," the invention of Mr. T. Hughes, reproduced, with slight alterations in the position of the figures, from his publication, "The English Wire Gauge." I cannot ascertain whether or not it has been adopted by many wire-drawers or workers, and would thank anyone acquainted with any firm using this gauge to announce the fact to me. I shall say nothing further upon the merits or demerits of the article than to remark that its length is a prominent impediment. I might suggest that, if made similarly, with graduated groove, but round—that is to say, its two ends almost meeting—it, perchance, would be an improvement. I am aware that there would then be an inner and an outer diameter formed by the groove, but I fail to see that this would materially affect its utility or accuracy. I reproduce the design here, knowing full well that it will be brought before numerous readers who may not have heard of Mr. Hughes's interesting book.

## A TANGENT GALVANOMETER FOR WOOD-TURNERS.

BY H. A. MILES.

DESCRIPTION OF POST OFFICE TANGENT GALVANOMETER—HOW TO MAKE A SIMPLER, THOUGH EQUALLY EFFECTIVE, FORM—DESCRIPTION OF PARTS—HOW VARIOUS PORTIONS ARE CONNECTED—MATERIALS REQUIRED—METHOD OF PREPARING TURNED PARTS—LINING INSIDE OF INDEX BOX WITH TINFOIL—GLASS REQUIRED—USE OF MIRROR—DRILLING NECESSARY—DIVISION OF INDEX—PREFERABLE ALTERNATIVE — PIVOTING OF MAGNET — SUSPENDING SAME BY SILK THREAD — NEEDLE — BEST LENGTH — INDICATOR — WINDING OF COILS—GAUGES OF WIRE TO BE USED—CONNECTIONS OF COILS ON BASE—USE OF SHORT CIRCUITING KEY—LEVELLING SCREWS—HOW MADE—USE OF THE INSTRUMENT — EXAMPLE — SHUNTING PART OF CURRENT—CONCLUSION.

THERE is always a demand amongst amateur wood-turners for designs of simple articles which are effective in appearance, and yet do not require an extraordinary degree of manipulative skill in their construction. I therefore propose to show how a turner of average, or even limited, ability may make a handsome article at a very small cost.

Those who have studied electricity will not require to be told the use of a tangent galvanometer, which is a costly though beautiful instrument. Those used in the post office, for instance, which are of the best design, are all of brass, with adjustable controlling magnet, micrometer levelling screws, etc., and are so arranged that the upper portion may move through an arc of a circle independently of the stand.

The instrument I shall describe was designed for the use of electrical engineering students who wished to construct their own apparatus, and was made of mahogany.

Fig. 1 is a front elevation of the completed instrument. A is the ring which contains the coils of wire ; B is the box in which the index plate and magnet are placed ; C is its support ; D the support for the ring and box ; and E the base.

Fig. 2 is a section of Fig. 1, and shows the manner in which the various portions are fixed together.

The mahogany required will be a piece 1 in. in thickness, sawn roughly to a circle $9\frac{1}{2}$ in. in diameter. A circle 2 in. in thickness and 6 in. in diameter, another $1\frac{1}{2}$ in. in thickness and $9\frac{1}{2}$ in. in diameter, about 6 in. of 3 in. square, and a few odd pieces of small size.

To commence, fasten the piece of 1 in. stuff on the taper screw chuck, and face up one side. Reverse it, and then true up the other side for a couple of inches from the outside, and cut the groove for the wires—$\frac{1}{2}$ in. wide by $\frac{3}{8}$ in. deep—on its periphery. The edges of the flanges should now be neatly rounded and papered up on both sides, after which the ring may be cut off with a parting tool, the inside dimensions being 7 in. The inner edges will probably be slightly rough, and may be papered off by hand, or a piece of stuff may be chucked, and a recess turned on its face, into which the ring fits, friction tight, a little chalk being used to prevent any slight slipping. All being now finished, it should be put away till wanted for polishing.

The piece left on the chuck must also be put aside, as it will be utilised in making the cap for the index box.

This may now be commenced. The 2 in. stuff should be chucked and faced up, leaving it of the shape shown in the section. The projecting portion being 2 in. in diameter by $\frac{1}{4}$ in. in depth, this side must now be chucked and the stuff turned down to a diameter of $5\frac{1}{2}$ in. The inside may now be removed to a depth of $1\frac{1}{2}$ in., leaving the bottom $\frac{1}{4}$ in. thick. The bottom may have a small bead run round, and the edge of the box must be rebated to take the cap, as shown in Fig. 2.

Now remove the box from the chuck, and replace the disc from which the ring was cut. This must be turned down so that the box will fit easily and yet not loosely, the rebate being of sufficient depth to allow for the thickness of the glass. The outside may be roughed into shape and the cap cut off, when the box must be rechucked, the cap fitted on with a little chalk, and neatly finished off with glass-paper.

The projection on the bottom should now be partly cut away, as to leave a tapering dovetail, which fits into a corresponding mortice in its support.

Before proceeding with the box support, etc., it would, perhaps, be advisable to turn up the base, and then work upwards. The base, which is of $1\frac{1}{2}$ in. stuff in the rough, should be faced up true on one side, reversed, and the edge of the other side trued up, and the middle recessed $\frac{1}{4}$ in. deep to within 1 in. of the edges. A bold moulding should now be turned on its circumference. A parting tool cutting a hole in the centre about 1 in. diameter will now remove it from the chuck.

The ring support, D, should next be done up, being made from 3 in. stuff. The bottom should be turned to fit the centre hole in the base, and a $\frac{1}{4}$ in. hole bored right through for the passage of the wires connecting the coils with the terminals in the base. A slot must now be carefully cut with a fine saw, into which the ring must tightly fit. The ring should now be marked, so as to be able to replace it in its exact position again ; care being taken that the grain of the wood is either horizontal or vertical, the former, to my mind, having the best appearance. A $\frac{1}{4}$ in. hole must now be cut in the portion of the ring which fits in the slot, and the base of the box support turned so as to "cap" the other one, and fit into the hole in the ring by means of a projecting pin—the top being fitted with a dovetailed recess as shown in perspective in Fig. 3, corresponding to the dovetail left on the under surface of the index box.

The woodwork is now complete, and should be nicely polished ; the interior of the index box should, however, be left plain, its sides subsequently being covered with tinfoil neatly glued all round to reflect the light on to the index plate.

If the galvanometer is to be fitted with levelling screws, three will be required, and I shall refer to this at a future stage ; but if not, three small knobs should be turned up, all exactly the same thickness, and glued in their places underneath, as shown in Fig. 2, the pins fitting into the holes bored for their reception.

The wood-turner's portion is now finished, and he may survey with pardonable pride the neat appearance his work will present if it has been conscientiously done, and the directions given have been properly followed.

The next stage will be to get a piece of looking-glass to fit inside the index box, and a piece of plain glass to fit *on* its edge inside the cap, the latter maintaining it in position. A small hole should be drilled in the centre of each.

The division of the scales on the index is a matter requiring great accuracy, and a deal of trouble would be saved by taking a walk yourself, or sending that convenient acquisition, a young brother, to the nearest newsvendor's, there purchasing a duplicate of this number of WORK, and cutting out the index, which may then be fastened to the looking-glass, using paste and glue. When dry, the two portions marked × may be cut round with a sharp knife, and carefully removed. For those who would prefer to make the scales themselves, I have shown the means of obtaining the tangent divisions (Fig. 4). The use of the mirror is to prevent errors due to parallax, as if the eye is exactly over the needle its reflection on the glass will not be visible.

The important question has now to be decided as to whether the magnet and pointer shall be balanced on a pivot, or suspended by a cocoon thread. I need hardly say that the former is vastly superior to the latter, though proportionately more difficult. If it is decided to suspend the needle, the silk thread is secured in the hole in the glass cover by a little shellac, and the needle fastened to its other extremity as near as possible to the index.

I shall, however, take it for granted that the larger proportion of my readers will prefer to pivot it properly, and make a good job of it.

A sewing needle driven upwards through the bottom of the box so as to project about $\frac{1}{4}$ in. through the centre hole in the mirror will make a splendid pivot. The surplus part underneath may be broken off out of the way.

The needle now claims attention. It may with safety be made $\frac{3}{4}$ in. long without introducing any perceptible source of error considering the diameter of the coil, and should be about $\frac{3}{16}$ in. wide and $\frac{3}{32}$ in. thick.

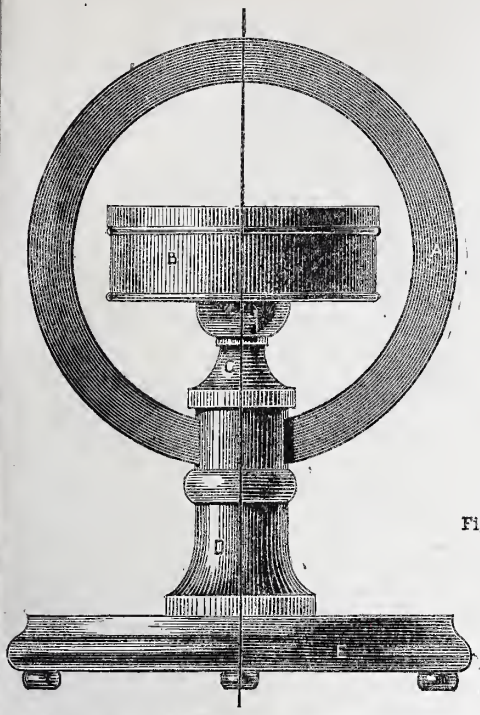

Fig. 1.—Front Elevation of completed Instrument.

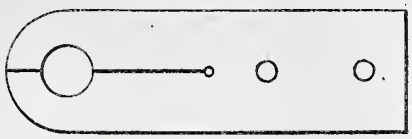

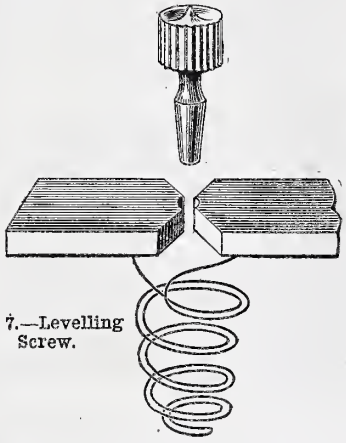

Fig. 7.—Levelling Screw.

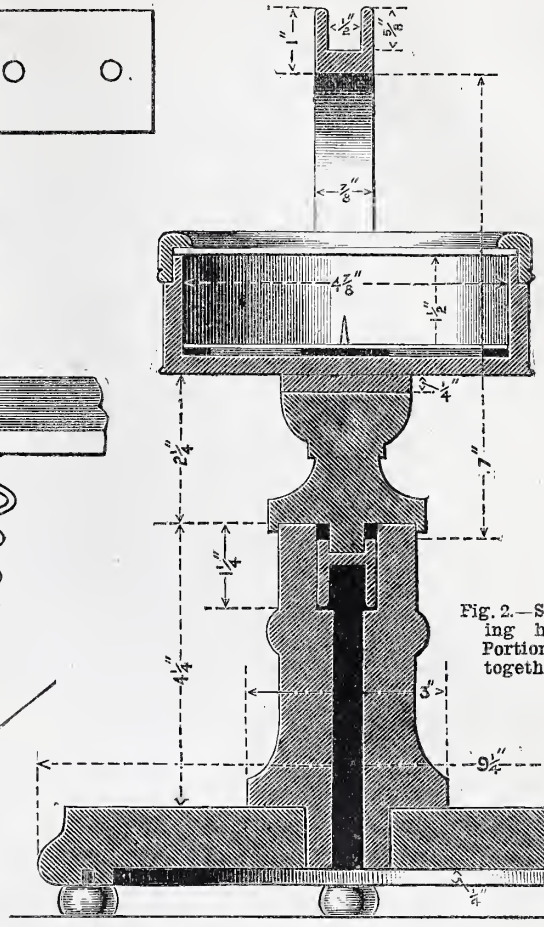

Fig. 2.—Section showing how various Portions are fixed together.

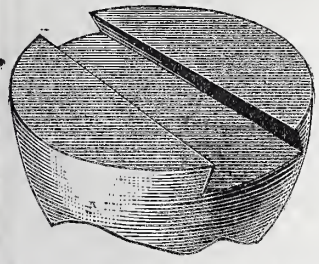

Fig. 3.—Dovetailed Recess in Top.

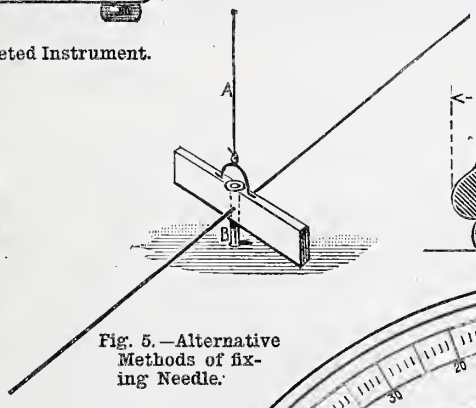

Fig. 5.—Alternative Methods of fixing Needle.

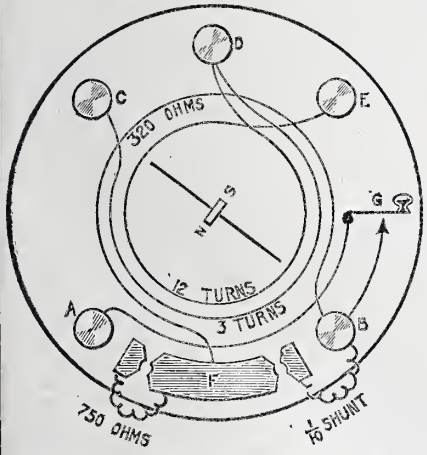

Fig. 6.—Resistance Blocks, Terminals, Wires, etc.

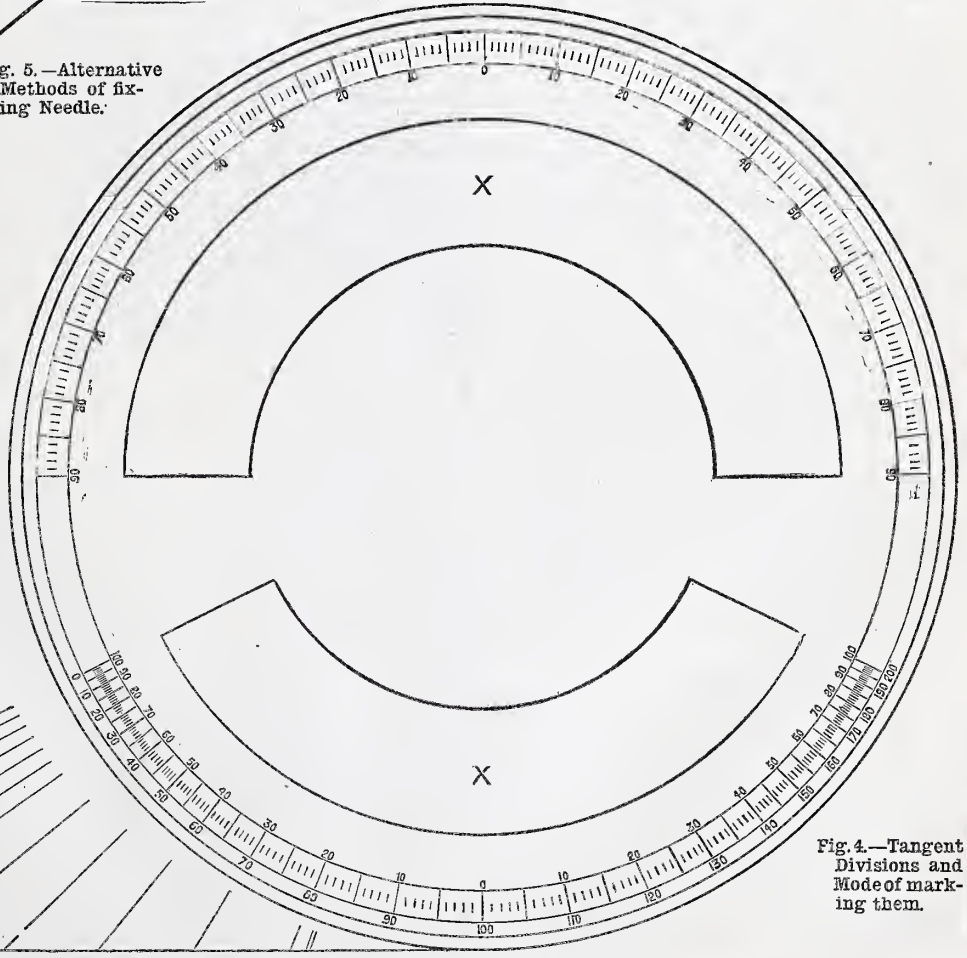

Fig. 4.—Tangent Divisions and Mode of marking them.

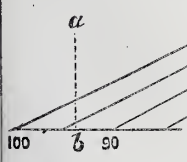

Fig. 4a.—Continuation of Fig. 4 to Left Hand.

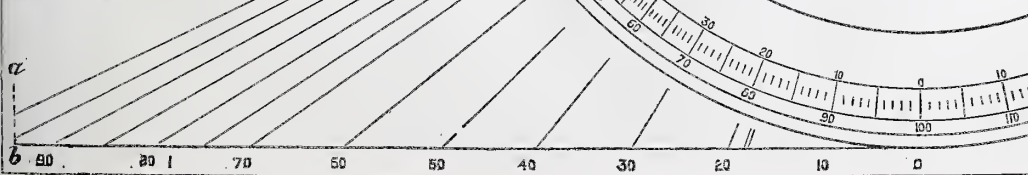

A hole should be drilled through the centre across the $\frac{3}{16}$ in. width, sufficiently large to allow the sewing needle to pass freely through. The needle should pivot on a jewel, as it is absolutely necessary to eliminate all possible friction. A jewel set in a small plate can be obtained at the watchmaker's, and fastened immediately over the hole by a little solder or shellac. A piece of very fine but hardened copper wire must now be fastened to the piece of steel, so as to form a straight line at right angles to it, and of sufficient length to reach the width of the index card. This pointer is the means employed to read the deflections shown on the scale. The accuracy of the pointer may be tested by observing whether its two points correspond to the zero on each side of the scale.

Fig. 5 shows the alternative methods of fitting the needle: A showing the silk thread means of suspension, and B the sewing needle pivot.

The winding of the coils may now be proceeded with, and wire of the following gauges, best quality, should be used.

Between the centre of the resistance blocks and the terminal B, No. 36 silk-covered copper wire of sufficent length to offer a resistance of 320$^w$ should be used; something over $\frac{1}{2}$ lb. will be required.

Between C and D, three turns, and between D and E, twelve turns, of No. 18 silk-covered copper wire, the three turns being wound in the opposite direction to the twelve turns.

The resistances inserted between the brass blocks are made up of No. 38 German silver wire, wound on a shallow reel under the base, the wire being doubled in half before being wound, as shown in Fig. 7.

The wires are neatly wound in the ring and passed through the hollow pillar and out below the base, where they are connected to the various terminals, as shown in Fig. 6.

When this has been done, a strip of patent leather may be fastened over them, so as to give a neat finish to the coil.

The small key shown at G, in Fig. 6, is for the purpose of checking the oscillations of the needle, and bringing it quickly to rest, the coils being short-circuited when the key is depressed.

Levelling screws, if required, may be made in the following manner—

Three pieces of rolled brass, $\frac{1}{4}$ in. by $\frac{5}{8}$ in., and 2 in. in length, may be neatly filed up, one end of each being rounded to a semicircle, as shown in Fig. 7, where also is seen the positions of the holes to be drilled. The hole at the rounded end should be tapped to take a convenient-sized thread, say $\frac{1}{4}$ in. Whitworth, though a fine instrument thread is far preferable. The end may now be sawn down for a short distance, and the ends slightly closed by a light tap with a mallet (to save denting the metal), so as to give a spring grip upon the screw. The two small holes at the other end are for the purpose of screwing it to the under side of the wooden base.

The levelling screws may be of any form. The heads should preferably be milled, and the ends rounded, so as to avoid scratching the surface of any polished table, etc., on which the instrument may be placed.

The galvanometer being completed, perhaps a few words as to the manner in which it is used will not be amiss.

Referring to Fig. 6, a current sent from C to E would give nine turns, acting on the needle, three of the twelve being neutralised by the three in the opposite direction between C and D.

The resistance of these coils is almost negligible, so that by using the various terminals effects can be obtained from three, nine, or twelve turns, without appreciably varying the resistance of the circuit.

The 320$^w$ coil is joined to the middle brass block and to B. If a plug is inserted in the left-hand hole, the end of the coil joined to the middle block is connected to terminal A direct. Without the insertion of this plug, however, an additional resistance of 750$^w$ is left in the circuit, and the resistance between A and B is 1,070$^w$.

The resistances are arranged for use with a Daniell cell of a comparatively low resistance, and if such a cell be joined to A and B, the current would be equal to $\frac{1{\cdot}07 \text{ volts}}{1070 \text{ ohms}}$, or ·001 ampere, viz., 1 milliampere.

If a current to be measured is very strong, a very high deflection will be the result, and to obviate the difficulties which would arise, the current is "shunted," or provided with a second path, so that only a portion passes through the galvanometer, the remainder passing through the shunt.

If the shunt was equal to the resistance of the coil, half the current would pass through each; but if the resistance of the shunt is $\frac{320}{9}$ ohms, then $\frac{9}{10}$ of the current will pass through the shunt, and only $\frac{1}{10}$ through the galvanometer.

This is the case in the instrument in question, the resistance being wound in the same way as previously described, and also placed beneath the base. The shunt is brought into play by inserting the right-hand plug.

Suppose a current of 1 milliampere gives a deflection of twenty-seven tangent divisions. If the tenth shunt is then inserted, and a deflection of eighty-one divisions obtained with a current of uncomputed strength, the current flowing round the galvanometer is evidently three milliamperes, but as this is only $\frac{1}{10}$ of the real strength, it follows that the total current is thirty milliamperes.

I do not profess to have explained the theory of, or more than touched upon the method of, using the tangent galvanometer, and have no wish to trespass upon the domains of our electrical contributors; but persons unacquainted with its use will not require to make it, and those who do understand it are not in want of any explanation. The coils requiring to be of a specified resistance should be tested carefully by means of a Wheatstone bridge.

In a future paper I hope to show how a simple bridge may be constructed.

## OUR GUIDE TO GOOD THINGS.

### 4.—The Britannia Company's No. 8 Fret-Saw Machine.

From the time of its introduction the Britannia Company's "No. 8" machine has been a favourite one with fret-cutters who could appreciate its numerous good features. The makers have, however, not been content to rest on their oars, but have, from time to time, introduced improvements as they have been suggested, till the "Improved No. 8," as the newest form of the machine is called, is as nearly perfect as possible. All the chief points of the original, the heavy driving wheel, large table, equal tension of the saw with perpendicular action, etc., have all been preserved, so that in general the machine remains much as it was. Closer examination, however, shows that there are several well-thought-out improvements, which cannot fail to be appreciated alike by the novice and the experienced worker. Comparing the present with the original machine, the vertical drill, in addition to the one at the side, is the most prominent feature which attracts attention, but, beyond this, there are several minor improvements which conduce to the comfort of the worker. Perhaps the most important of these is the facility with which the saws can be fitted, as the fumbling which so often happens to fit them into the clamps is done away with by a very simple expedient, which allows them to be fixed with the greatest ease. The tilting arrangement has also been simplified, while the saucer-like receptacle for sawdust underneath the table, where it was sometimes in the way when fastening the saws, has been done away with. The stroke of the saw has been increased, as has likewise the distance between the table and the upper arm of the frame. This by no means exhausts the list of improvements; but the others are of comparative unimportance, although they all tend to make the machine what I consider the best both for amateurs and cabinet makers who do not require to cut anything over, say, $\frac{3}{4}$ in. thick, though, as an experiment, I have cut oak of considerably more. It almost goes without saying that the thinnest material and the finest saws can be used, when necessary, with equal facility. The price of the machine complete is 65s. I understand that the makers are contemplating a lathe attachment, which will be a great advantage to those fret-cutters who wish to do the small turned parts which are so often found in fretwork designs. When this is ready, no doubt I shall have something to say about it; meanwhile, readers who desire to know more about it cannot do better than apply to the Britannia Company direct.

### 5.—Some Useful Books, etc.

**The Amateur.**—I have received the *Amateur* for March, 1891, published by Messrs. Henry Zilles & Co., 24 and 26, Wilson Street, Finsbury, London, E.C. It contains a very good pattern in fretwork for a bracket and towel-roller combined, which seems a somewhat incongruous bringing together of the drawing-room and back kitchen or scullery, for the towel-roller would not be wanted in the former apartment, and an elaborate bracket above the towel-roller is clearly a waste of ornamentation in the latter. The part also supplies an excellent design for an inlaid table in olive wood, curled walnut, and rosewood.

**Development.**—This handy volume on an important branch of photography, written by Mr. Lyonel Clark, C.E., author of "Platinum Toning," forms Vol. V. of "The Amateur Photographer's Library," published by Messrs. Hazell, Watson, & Viney, Limited, 1, Creed Lane, Ludgate Hill, London, E.C. It includes instructions for the use of eikonogen as a developer for instantaneous work and a comparison of developers.

**The Electro-Platers' Handbook.**—Our friend Mr. George Edwinson Bonney, who by this time is well known to all readers of Work as an authority on all matters connected with electro-metallurgy and kindred subjects, has written this volume of Whittaker's Library of Arts, Sciences, Manufactures, and Industries, published at 3s. by Messrs. Whittaker & Co., 2, White Hart Street, Paternoster Square, London, E.C., "to meet the wants of amateurs and young workmen desiring a practical manual on electro-plating at a low cost." It is written in Mr. Bonney's careful, painstaking, and explanatory style, and cannot fail to answer the purpose that he has in view.

**Ventilation.**—This is a thoroughly practical and exhaustive volume on the important subject of ventilation, written by Mr. William Paton Buchan, R.P., Sanitary and Ventilating Engineer, author of "Plumbing." It is, as it purports to be, a complete guide and text-book to the practice of the art of ventilating buildings, and contains instructions on air-testing, giving various methods of examining the air of buildings. It is published at 3s. 6d. by Messrs. Crosby Lockwood & Co., 7, Stationers' Hall Court, Ludgate Hill, London, E.C., and forms a volume of Weale's Rudimentary Series.

The Editor.

## SHOP:

A CORNER FOR THOSE WHO WANT TO TALK IT.

*** In consequence of the great pressure upon the "Shop" columns of WORK, contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of WORK in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

II.—QUESTIONS ANSWERED BY EDITOR AND STAFF.

**Furniture Colouring.**—W. N. (*Sheffield*).—I am afraid you are not such a careful reader of "Shop" as you say you are, or you would have seen not very long ago an answer to a correspondent on the same subject. As your signature is somewhat illegible, and I cannot turn up the inquiry then answered, I am unable to say whether it is not the one you refer to as having been lost. You know it is really impossible to give answers to questions at once, as the "Shop" columns are limited in extent. It is not worth while repeating remarks so lately given, so I can only briefly answer your present inquiry. Take the colouring of your walls, and paint your furniture similarly. The more colours you use, and the more pronounced they are, the greater the liability to failure. Low tones or light, almost white, colours are generally the most successful. Without knowing something of the prevalent colours of the room in which the furniture is to stand, how is it possible to advise you on what will be best either from Aspinall's or any other paint-maker's cards? If you use white polish, it will not affect the colour; but, of course, if you use dark polish, the colour will be modified accordingly. Get a machinist to do what is necessary to your lathe. I do not think you can do it yourself.—D. D.

**Stove and Fret Saw.**—ARTIST IN WOOD.—Your stove seems practicable enough, as it does not differ essentially from many now in use. It it just such a thing as anyone who has to do sufficient veneering to make it worth his while to have a special stove for heating cauls could construct or arrange for himself. No doubt you know that, in ordinary circumstances, the usual open fireplace is quite sufficient. I am sorry to say that I am so dense as to be unable to make head or tail of the description of your new form of scroll saw. Therefore, to say that it is very good would be flattery of the most senseless kind; while, on the other hand, to say that the idea is worthless, might possibly be the means of discouraging you, and preventing what may be a really good thing from being brought forward. To go into all the parts which I do not understand would entail too much time, but if your invention has got further than paper, and a machine has been made on the lines you dimly suggest, let us have a description in which the blanks of your present one are filled up. Such little omissions as source of motive power, disposition of top end of saw, and one or two trifles of that kind, do not exactly help one to understand your meaning. Life is too short to spend many days in trying to work out a mechanical puzzle of the kind you put before us.—D. D.

**Polishing Alabaster.**—MONUMENTAL MASON.—This is an inquiry for "full details," and yet there is no indication, except, perhaps, the signature which points to carved doves, whether the work to be polished is flat, turned, or carved. Space is too precious to go into all the tools and methods employed, so the following summary is submitted with the hope that it will give the information required; if it does not, then write again. I will suppose that the work has already a good smooth surface left from either rifflers, scrapers, or glass-paper. Now use some fine sand-stone or grit-stone, such as robin hood, water of Ayr, or snake-stone, or else trent sand and water, until you get rid of all tool marks; follow on with pumice, either in lump or powder, also with water; next use putty powder and water, and for a finish I am told soap and water is particularly good to use with the putty powder, especially for lathe work. As to the way in which you will apply these materials, that must rest with yourself, as I have no details to guide me. If for crevices in carvings, a soft stick will best hold the polishing powder. For choice, get some dog-wood—that is, what butcher's skewers are made of. Then for other forms, buffs of leather, pads made of cloth, either to use by the hand or to revolve in the lathe, or dollies of wool or list, also for the lathe, may be required, while the hand itself may be used to give it an extra finish.—H. S. G.

**Bird Cages.**—A. T. (*Inverness*).—There are probably few readers of WORK who do not keep a canary or a bird of some kind, and perhaps some of them would like to see their songster in a large cage. I will give instructions how to make a cage—a cage that is roomy, ornamental, and not difficult to make. The one illustrated (Fig. 1) is a square cage, standing upon a table. The eight uprights are of ⅜ in., and the rest is of ½ in. mahogany. The top is in one solid piece, with a round hole cut for the dome. After the wiring is done in the bottom part, the top is simply glued on the eight uprights, as in Fig. 4. To wire the dome, divide round the circle with a compass ½ in.; for the top of the dome, have a round piece of mahogany; divide that into the same number of parts; bore the holes, then cut a number of wires the length, to give the dome a pleasing curve; fasten a wire in the bottom and in the top piece, and bend it to the proper shape; then put one in each corner; and now go all round, bending each wire. For binding and straightening the wire, see page 29, No. 54, Vol. II. of WORK. A simple breeding cage, if it is wanted to hang in a large room for the season only, could be made of ⅜ in. pine, put together as in the drawing (Fig. 2). There is no pretension to ornament: it is a simple

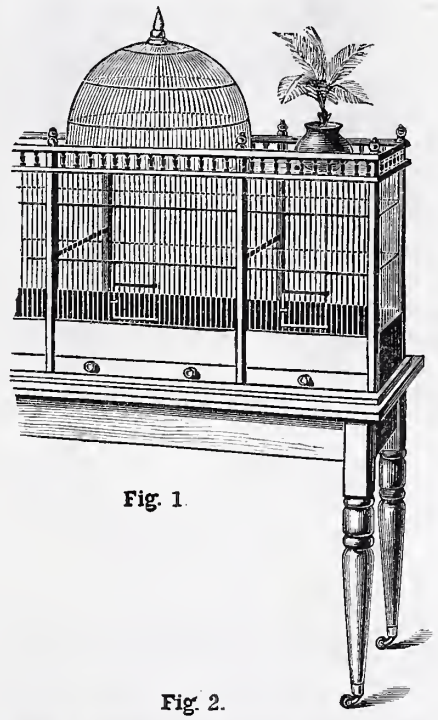

Fig. 1.

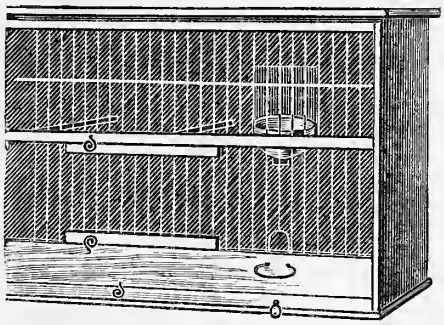

Fig. 2.

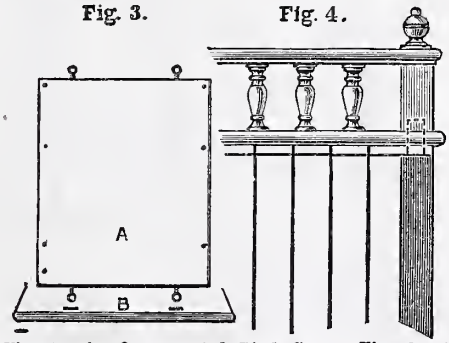

Fig. 3.

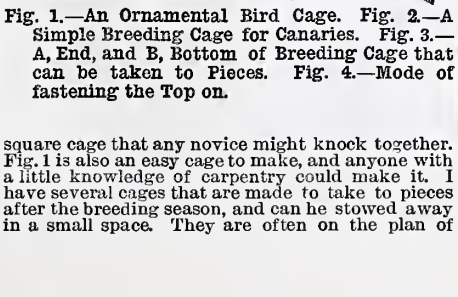

Fig. 4.

**Fig. 1.—An Ornamental Bird Cage. Fig. 2.—A Simple Breeding Cage for Canaries. Fig. 3.—A, End, and B, Bottom of Breeding Cage that can be taken to Pieces. Fig. 4.—Mode of fastening the Top on.**

square cage that any novice might knock together. Fig. 1 is also an easy cage to make, and anyone with a little knowledge of carpentry could make it. I have several cages that are made to take to pieces after the breeding season, and can be stowed away in a small space. They are often on the plan of Fig. 2, but I should not care to keep the birds all the year round in a deal cage. I will now describe how to make a simple breeding cage. List of pieces required:—Two pieces for top and bottom, 24 in. by 11 in.; two pieces for sides, 14 in. by 10¾ in.; one piece for back, 23 in. by 10¾ in.; one piece for false bottom, 23 in. by 10⅜ in.; for front, three strips, 23 in. by ½ in.; one strip, 23 in. by 2 in. Plane all these pieces both sides, and before putting the cage together, stain and varnish the outside and white-wash the inside. Now mark the pieces for the wire, ½ in. apart; you can do this with a rule or a stiff compass, but if you are making several cages, it will save time if you make a marker, as described in WORK, No. 54, page 20. You can bore the holes in soft wood with a hradawl; take care to have it sharp, and cut across the grain; bore holes right through on strip of ½ in., and half-way through the others; cut one of the ½ in. strips into two pieces, 5 in. long, for the door, and put the door together with seven short wires. Having bored the last hole right through, and shaved the other ends so that the door will shut flush, put the wires through the centre strip, and get them all level; get the top strip on next, beginning at the end; pinch each wire with the pliers, and give the pliers a slight tap; leave out seven wires in the centre of the cage for the door, and put the door on the eight wires; cut about 1½ in. off the seventh wire from each end of the cage for the food and water fountains; turn up, and drive the wires into the bottom strip, taking care that they are parallel. Bore holes, and put the wire in for the fountains, and take care to fasten the ends in well; cut a slant for a feeding tin. Now the front is ready: nail the end on the back and front, then the bottom, and lastly, the top and the front strip on to the false bottom; make the fastenings for the door; fit and fix the perches in. The drawings will assist the amateur to make a simple breeding cage. There is a very good nesting basket described in WORK, Vol. II., No. 95, page 699, which I have found to answer the purpose; such can easily be fixed to the back of the cage.—F. H.

**Spokes.**—WOOD-WORKER.—First get your spokes for the heavy cart dressed off. When the hub or nave is turned, you will see that the wood-turner has marked a line with his chisel. This guide-line is nearer to the front than the back. When marking and driving home the spoke in the nave, the face of the spoke at the bottom must be in a dead line with this guide-line. If the wheel has twelve spokes, we divide the nave into twelve equal parts with a pair of compasses 1 in. behind the guide-line; when found, mark the division well by digging the compass-point well in the nave. Next, fix the nave in the pit-frame, and bore half-way through with a 1 in. bit at every mark or division. In boring, always have the bit perfectly perpendicular. When all are bored, get a dressed spoke and place the tang or foot of it just over a hole, and the face of the spoke in a dead line with the guide-line, and let the spoke be placed exactly between the other two holes at each side of the spoke; next run your pencil round the two sides and the back, thus marking the nave. We now pare this mortice out within the lines, and drive in the spoke, using a spoke-hoy or stick set right to guide us in driving the spoke in properly. We now miss a mortice, and go on to the next and serve it in exactly the same way as we did the first; thus six spokes are driven in alternately, leaving a space between every two spokes to receive another after the first six are in. If all the spokes were driven in one after the other, the consequence would be that the nave would burst into halves. In light wheels, the spokes are dressed off differently from the cart fashion, and are driven in the nave on the on and off system alternately; therefore two guide-lines are turned upon the nave, the off guide-line being ⅛ in. behind the on or front guide-line. The strength of the timber for a heavy cart wheel is generally as follows:—Oak nave or hub, length 15 in. by 13 in. (in 6 in. wheels the spokes of English oak are 4 in. by 2 in.); felloes of ash or oak, 6 in. by 4½ in.; hoops or tyre, 6 in. by ⅜ in. thick; height of wheel when finished, 4 ft. 9 in. In 4½ in. heavy cart wheels the strength of the nave is the same; the spokes are 3½ in. by 1¾ in.; felloes, 4½ in. by 3½ in. or 4 in.; tyre, 4½ in. wide, ⅜ in. thick; height of wheel when finished, 4 ft. 6 in. or 8 in. The strength of timber for wheels for a light trap is: nave of elm, 9 in. by 8 in.; felloes of ash, 2½ in. thick; oak or hickory spokes, 2 in. by 1⅜ in. thick; tyre, 1⅜ in. wide, ⅛ in. thick: the lengths of the spokes go according to the height of the wheel. A pair of wheels suitable for light spring-cart for a pony of thirteen hands would be about 4 ft. high.—W. P.

**Platinum.**—J. W. (*Homerton*).—Write your wants fully to Messrs. Johnson, Matthey & Co., Hatton Garden, London, E.C., who will doubtless reply to you.

**Silvering on Glass.**—W. E. L. B. (*King's Norton*) from information given in WORK has succeeded in silvering glass in the ordinary way: he now asks information on chemical silvering. May I ask if W. E. L. B. intends to work simply experimentally or on a large scale for profit? If the former, I think I can help him; if the latter, something more than information will be needed. I have never had occasion to silver by this process, but I have secured information from a reliable source which I am pleased to impart to the inquirer. There are several processes; the following I give with confidence. *Silvering Solution.*—Dissolve forty-eight grains of crystallised nitrate of silver in 1 oz. of distilled water. Add strong liquid ammonia drop by drop, stirring

at the same time with a glass rod—the stirring must be continued until the brown precipitate is nearly, but not quite, re-dissolved. It must now be filtered and distilled, and water added to make up to twelve fluid drachms. *Reducing Solution.*—Dissolve twelve grains of Rochelle salt in 1 oz. of distilled water. Boil in a flask, and whilst boiling add two grains of crystallised nitrate of silver dissolved in one drachm of water. Let it boil five or six minutes after the latter has been added. Filter when cold, and add distilled water to make twelve fluid drachms. *Silvering.*—The glass to be silvered must be *chemically clean.* To secure this, dip it in strong nitric acid. Then wash in liquor potassæ, and finally wash in distilled water. To have the glass approximately clean is not enough. Chemicals are very particular as to what company they keep, and positively refuse to act unless they are consulted. In a glass vessel of a size suitable to the glass to be silvered, equal portions of the two solutions must be poured, and stirred so as to be intimately mixed. Previous to this, some plan must be devised by which the glass can be gradually lowered into the vessel. For example, a piece of wire may be cemented to the side of the glass not to be silvered, and be made to pass through a hole in a piece of thin board; this may be placed across the mouth of the vessel; the glass attached to the wire can then be raised or lowered. The glass, whilst still wet from the bath in distilled water, must be let down into the solution. The utmost care must be taken that the entire surface touches the solution without any air-bubbles between. The vessel must be set in the sunshine in a warm room. The light soon turns the fluid black, which gradually grows clear as the silver is deposited. It must at this point be removed, for if left after the solution is exhausted, the silver will be partly re-dissolved. When the mirror is removed from the bath, it must be carefully washed in distilled water and placed on its edge to drain and dry. When perfectly dry, the silver must be varnished with an elastic varnish or paint to prevent damage. I shall be pleased to give further details if needed.—O. B.

**To Soften Gold.**—H. H. W. (*Pimlico*).—To soften gold or silver after hammering, all that has to be done is to anneal it—that is, make it red hot, and let it cool or quench it in water, when it will be as soft as ever it was. Experience will teach you that the heat should be applied regularly, gently, and gradually; that to make the part near a soldering seam hot first of all will cause it to open; that a sudden quenching is bad. These, and many other things, will be found out by experience, for on the application of heat for soldering and annealing, one of our foremost jewellers (Giuliam of Piccadilly) says that it takes an apprenticeship of seven years to master. This applies only to the work if of good size and of complicated design. For every-day work, no difficulty is likely to be experienced.—H. S. G.

**Silver Foil.**—CAROL.—This preparation is generally believed to be a French production, and from experience with it in the workshop as a finished article, I should say that it would be a very difficult matter to keep the thin silver flat, smooth, and bright while the paint—which I believe is put on when warm—is being evenly applied. You might make inquiries at the flatting mills (Buckland Hop Gardens, St. Martin's Lane) as to the thinness they can flat silver to; if too thick, then try a gold beater. When you have got your silver thin enough, you have to find somebody to burnish it. The next thing will be to obtain the paint. All I know about that is, that it can be bought at jewellers' material shops in various colours—named after the stones. Of its composition I have never thought, but rather suspect if I really wanted to know that, I should get a chemist to analyse some. The foregoing is merely an indication of what I think is the manner of proceeding. The game can never be worth the candle. If, however, you intend going in for it in large quantities, no doubt the Editor will put a query at the end of "Shop," and I will as well spend some time in going into the matter, if you will but write again.—H. S. G.

**Angle Iron.**—W. C. (*West Bromwich*).—The iron mentioned in answer to A. S. (*Forest Gate*) is not *angle* iron, but iron of "rectangular" (oblong) section. I do not think you can get angle iron so small, but upon this point you could get information from any manufacturer of iron bedsteads. I believe they use the smallest angle iron rolled.—F. C.

**Staining and Polishing.**—L. G. (*Middleton*).—To stain your light wood chest of drawers a nice mahogany colour, darken it first with a weak walnut stain, and then finish off with French polish, reddened with a little Bismarck brown. The work connected with the polishing is done exactly as if you were treating unstained wood, but it may be necessary to remind you that if the staining raises the grain, as it probably will, you must rub down with fine glass-paper. If you prefer to use a ready-made mahogany stain, you can buy one at almost any oil shop.—D. D.

**Book on Joinery.**—E. W. C. (*New Wandsworth*).—Joinery and cabinet-making are distinct trades, and the details, etc., given in books are, properly speaking, examples, and not working drawings. You would find Tarn's "Carpentry and Joinery" (2 vols.), published by Crosby Lockwood and Co., 7, Stationers' Hall Court, London, E.C., very useful. "Drawing for Cabinet Makers," by Davidson, published by Cassell & Company, Ludgate Hill, E.C., is also a very good book.—E. D.

**Gun Rack.**—J. H. (*Lancashire*).—This simple device should be found satisfactory accommodation for three guns and cartridges, unless you object to having their muzzles pointing nearly horizontally. The thicker the side brackets are the better—even 1½ in. or 1½ in. would not be too stout. Connect the ends of a back rail to the brackets after some such method as I show in Fig. 3. You must have noticed sufficient details elsewhere, applicable to the construction of the cartridge compartments, which I advise you to have as a box, with lid, in preference to drawers. To retain the guns in the position shown, it will be necessary to have hook-shaped

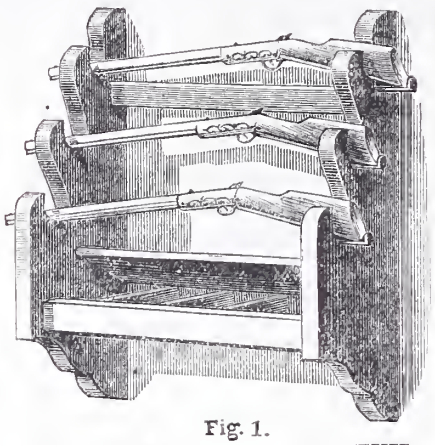

Fig. 1.

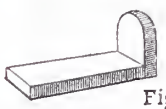

Fig. 2.

Fig. 3.

Fig. 1.—Gun Rack. Fig. 2.—Gun Stock Support. Fig. 3.—How to join Back Rail.

rails, as in Fig. 2, joined to one side of the article, against which will rest the stocks. By placing the guns as I show, their triggers will be less exposed to contact with coat sleeves, when a gun is being taken from the rack, than if stowed each flush with the other.—J. S.

**Concrete.**—H. A. H. (*Manitoba*).—(1) Concrete is made of four parts of broken stones, made to pass through a 2 in. ring, two parts of fine gravel or coarse sand, and one part of Portland cement. These must be measured in a box without top or bottom, and laid on a platform of boards, and turned over with shovel and pickaxe till thoroughly mixed;

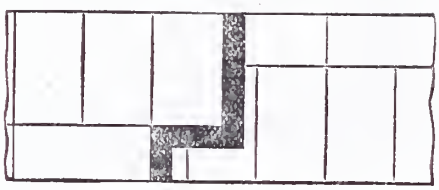

Fig. 1.

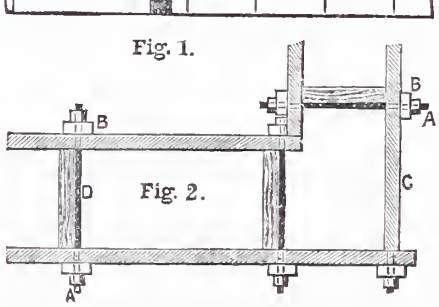

Fig. 2.

Fig. 1.—Binding of Wall. Fig. 2.—Frame for Concrete Building.

then sprinkle water on, and turn over till every part is wetted, but not saturated; it is then fit for use. (2) Walls 16 feet high can be built with it, and if all the moisture is dried out of them, they will not be affected by frost. Should there be any moisture left in, the frost will crack it, but to what extent can only be learnt by experience. If any concrete has been used in the district, you could note the effect of the frost upon it. If you have six months of dry weather after being built, the concrete should be dry. If the climate is wet, you might mould the concrete into blocks—say 12 in. by 6 in. by 3 in.—and wall them as ordinary bricks, binding them as in Fig. 1. For these the concrete must be screened through a ¾ in. screen. (3) The method of building in concrete is by frames 12 in. to 18 in. deep, kept apart by pieces of wood, and a row of ½ in. bolts 3 feet apart at the top and bottom. Washers or iron plates should be put on at the outside, and battens on the outside of the frame, which may be of 1 in. boards. The frame is filled with concrete, and when sufficiently set, the frame is moved along, and again filled, and so on round the building. Then commence a second course, and carry it round in the same manner. When the bolts pass through the concrete, lay a piece of board at each side, to prevent the concrete adhering to the bolts. The holes can be filled up afterwards. Fig. 2 shows the frames. For building flues, use a round core, 10 in. or 12 in. in diameter, with a handle on the top; fill round this with concrete, and, when set, draw the core up. Window and door frames are walled in, a board being fixed at each side of the frame to fill out the thickness of the wall. Two frames will be enough, except for a very large building. After the walls are up, render and float them inside and outside with Portland cement mixed with three times its bulk of sharp sand. (1) The outer walls may be 16 in. or 18 in. thick, and the inner walls 10 in. or 12 in.—M.

**Smelting Furnace.**—J. G. N. (*Manchester*).—A drawing of such a furnace is given in Bloxam's "Metals," page 314.—J.

**Colouring Gold Chains and Whitening Silver Ones.**—NEW SUBSCRIBER.—Your best plan will be to send both sorts to a gilder to be renovated, for there are many considerations that govern the use of the following methods, the chief being the qualities of the gold and silver that are to be coloured or whitened. For colouring, you will find all the details given in a reply to YOUNG AMATEUR in No. 19 of WORK, page 301. If the gold chains are not worn, but only discoloured, you can restore them by laying them in a mixture of chloride of lime one part, water ten parts. Afterwards rinse well in hot water and dry in warm sawdust. Neither of these methods to be used for any quality under 15-carat gold. To whiten silver, neither of the two following methods are to be tried on anything less than standard silver, and they only give good results at the first attempt when the silver is fine, such as is used in filigree work. Cover the work over entirely by the aid of a brush, with borax ground up with water on a piece of slate until it is as thick as cream. Then make it red hot, and drop it into a clean warm solution of vitriol one part, water about thirty parts. If it does not come out white on the first application, repeat the process two or three times. Another way is to cover the work with powdered charcoal and powdered saltpetre, mixed together with water in the proportion of three or four of the first to one of the last. Then anneal and boil out in the vitriol pickle given above, or else make this solution in its place: bi-sulphate of potash one part, water ten parts, and clean your work in that. After either of these, the work must be well rinsed in hot water previous to being dried in warm sawdust. To scratch-brush you can use soap and water, but diluted beer is better. Perhaps this method will do what you require: Take a piece of cyanide of potassium about the size of a lump of loaf sugar and dissolve it in a half-pint of warm water, then immerse your chains for a few minutes until the tarnish has gone off, then rinse, etc. To clean them only, an easy method is to apply whiting moistened with ammonia diluted with at least an equal quantity of water, using a soft brush. If you are thinking of trying any of these, first examine your work to see that there is no pewter solder on it, and in the case of gold there must be no silver solder about. It is safest to do as I advise at the beginning of this reply—send them to the gilder. Your signature is evidently a correct one, or else you would have seen that Mr. Bonney has a series of articles in this paper dealing with the subject of electro gilding.—H. S. G.

**Power of Water delivered through Pipe.**—GOSFORTH.—This must be treated by a formula for the flow of water through pipes, and the head will be $a$ plus $d$, assuming that no tank intervenes. To ascertain the power, we must calculate the discharge at the delivery point, and the *work* accumulated in the water at that point. This will be best shown by an example. Let $a$=10 ft.; $d$=50 ft.; $y$=100 ft.; and $x$=2 ft. The total head $h=a+d=60$ ft. Then if Q=cubic feet of water discharged per minute, we find by Downing's formula:—

$$Q = 2{,}356\sqrt{\frac{h}{y}}\times x^5 = 2{,}356\sqrt{\frac{60}{100}}\times 2^5 = 10{,}270 \text{ cubic ft.}$$

One cubic foot of water weighs 62½ lbs., therefore the *weight* of water delivered per minute will be $10{,}270\times 62\frac{1}{2}=64{,}185$ lbs. As the pipe is 2 ft. in diameter, its area is (from a table of areas) 3⅛ sq. ft. Dividing the quantity by this, we find the velocity per minute $\frac{10{,}270}{3\frac{1}{8}}=3{,}423$ feet per minute $=57$ feet per second. From the laws of falling bodies we find that the accumulated work in a body is equal to the product of its weight and the square of its velocity in feet per second divided by $64\frac{2}{5}$. In this case it equals $\frac{64{,}185\times(57)^2}{64\frac{2}{5}}=32{,}381{,}000$ foot-lbs. per minute. Now one horse-power is equal to 33,000 foot-lbs. per minute; therefore the horse-power given by the water will be $\frac{32{,}381{,}000}{33{,}000}=981$ horse-power.—F. C.

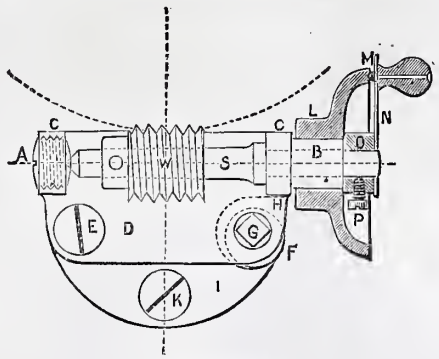
**Musical Box Repairs.**—SECRETARY.—First you say "pins out of barrel." Do I not tell how to re-pin the same in my article? "Three teeth in comb gone." I also state the best remedy unless you purchase

new comb; but three teeth you can insert, as I wrote. Now, as to working—and being a mechanic the job is easier to you—be sure to let it down to the bottom, or pins and teeth are broken by careless unscrewing of the fly-wheel; when spring has great power, off go lots of teeth and pins. Then do as I say—*clean* it thoroughly; not too much oil, and it will go easy and well. If not, see to the worm part. This part may be too far in—"too near its work," as you mechanics would say. If too far away—why, it would go to the bottom in two minutes or less; this you remedy by turning the screw from you (only a quarter-turn, or less) until it works, with pressure of your finger or thumb on the second wheel from worm.—PRACTICAL.

**Slide Painting.**—W. J. C. (*Islington*).—First, the colours used. Most dealers in artists' material supply boxes with all needful colours, etc. But it is not really requisite to procure a box, or, indeed, every colour that may be found in them. The following will be found sufficient for a beginner. W. J. C. doubtless is aware that all colours must be so-called transparent. *Red*—madder lake, crimson lake, pure orange, pure scarlet (this colour has been a difficulty, but a few months ago I received a tube from Messrs. Reeves, 113, Cheapside, London. It is a new paint, and I am informed that it is the result of much patient experimenting; the colour is exceedingly good, though it must be confessed that an absolutely pure scarlet in transparent colour remains to be discovered), burnt sienna. *Yellow*—yellow lake, gamboge, yellow madder, Italian pink. *Green*—verdigris. *Blue*—Chinese, Prussian, indigo, French ultramarine. *Brown*—vandyke, madder brown. (Madder lake and ultramarine are 1s., and the others from 3d. to 6d., per tube.) Varnishes will be needed. From W. J. C.'s letter, I fear he has been working without them, as he says his paint rubs off. Mastic, gold-size, copal, and pure turpentine, will meet his requirements. There is one little omission in W. J. C.'s letter; and that is, he does not say if he is working in oil or water. I am presuming, however, it is oil. Secondly, he asks, "Is there any way of putting them on, as I cannot get them on even?" They can not only be got on, but evenly too. I suppose the difficulty experienced is on large flat surfaces, as the sky. Now, if one looks minutely at a well-painted slide, he will see that the sky appears granulated, if I may so say. Sometimes circular marks similar to "thumb-marks" will be seen; colour is laid on the upper sky, and brought down near the horizon—from the horizon upwards to meet the blue. Yellow-red (or orange) is laid according to the effect required. These two colours are now blended together by means of the tip of the little finger. The finger makes little dabs accompanied by a somewhat rolling movement difficult to describe, but soon acquired by practice; by this means the two colours are blended in a perfectly even manner. If the colour is too thin on the glass, then a little is taken on the finger from the palette and dabbed on. On the other hand, if the colour is too thick, wipe the colour off the finger on the palm of the other hand, repeating this until the colour is brought to the proper intensity and depth. Some workers cover the top of the finger with the end of a white kid-glove, but practical men prefer as a rule to dispense with this addition. The last point referred to is—that when the paint is put on, it rubs off so easily. By this I am afraid that proper precautions have not been taken—first, in the use of proper varnish, such as I have mentioned; and, secondly, the slides have not been stoved in a warm (not hot) oven for the purpose of hardening the varnish. If proper varnish is used and hardened, there is no danger of the paint coming off. It must be understood that the first coat must be perfectly hard before the next is laid on. I have only given the colours as they are procured ready-mixed in the tubes, but it will be understood that any number of secondary colours may be made by a proper mixture of any two of the colours named. There is another word, I am afraid, necessary from W. J. C.'s letter in reference to the use of a medium with his colours. Mix mastic varnish ¾ oz., turps, one teaspoonful, and twenty drops of pale drying oil or gold-size together in a wide-mouthed bottle, and thin down all paints with it.—O. B.

**WORK Binding and Index.**—INDEX.—The price of the covers for binding WORK volume is 1s. 3d., and the Index 1d. of all booksellers. You would do well to have your numbers bound at your bookseller's, as the carriage backwards and forwards would be expensive.

**Wheel Cutting on "Go-Ahead" Lathe.**—INDEX.—If you wish to understand how dividing is done by worm and wheel, please read the article on page 113, Vol. I. of WORK. This will, I hope, make it quite plain how you may get any number of divisions from a given worm and wheel. You wish to fix a worm-wheel on the tail end of your mandrel, and the worm on the back of the headstock beneath: you might adopt a worm-wheel of 120 teeth, and a worm of ½ in. pitch = ·125. Multiplying ·125 by 120, you get the pitch circumference of the worm-wheel, 15 in.; dividing this by 3·1416, you find the diameter to be 4·77—say, $4\frac{25}{32}$. Now then, having 120 teeth in the worm-wheel, one turn of the worm-screw between each cut will give you 120 teeth or divisions; two turns, 60 teeth; three turns, 40 teeth; half a turn, 240 teeth, etc. Or, according to the rule given on page 215 of Vol. I., divide 120 by the number of divisions you require, and you get the number of turns, or the part of a turn, you must give to the screw between each cut. Now you will know that on the end of the screw you can put three different kinds of expedients for counting its revolutions or parts of a revolution; you may have, simplest of all, a divided collar, or a series of exchangeable collars having different numbers of divisions; or, secondly, you can have an index plate, or several plates—a system which is explained in Messrs. Brown & Sharpe's "Milling Machines," to be had from Buck & Hickman, or Churchill, for 6s. 6d.; or, thirdly, you can have a train of small wheels with a click, so arranged as to turn till the click falls into a notch between each cut. The plan explained in Vol. I. is a kind of cross between the two last, and is somewhat simpler than either, and I think it would suit you very well, as you are not continually employed in wheel cutting. The sketch below shows how you might arrange matters. The dotted arc is part of the pitch line of the worm-wheel; W is the worm, S the spindle which carries it; A is the centre screw confining its motion endways (it is made of large diameter, so that the collar of S can be passed through the tapped hole it leaves); B is the place on which the divided collars fit; C, C are the bosses on the plate D; E is the pivot screw which secures the plate D, and round which it can turn when raised into gear by turning the square, G, of the eccentric F; this eccentric bears upon the bottom of a recess H, cut out of the plate I, which plate, I, is secured to the back of the headstock by one or more screws, K, and may remain in position



**Wheel Cutting.**

even if D and its attachments be removed; L is a collar, of which there must be several; they fit on B by pressure of the hand, and have in their edge a number of shallow holes, into which the ball point M drops, and is held there by the spring N; O is the boss of the spring; it is fixed to the worm spindle in any position by the set screw P. Since you say you wish to cut wheels of from 60 to 80 teeth, divide 120 by every number of teeth you wish to cut—thus, $\frac{120}{60} = 2$, which means you require to turn the worm-screw round *twice* between each tooth. Some numbers, being primes, are very difficult to deal with except by the method indicated on page 215: these numbers are 61, 67, 69, 71, 73, 74, 77, 79. Very probably these numbers may not be required, and for the rest you will require ten collars, divided into 3, 5, 7, 8, 11, 13, 17, 19, 21, 23. These you could easily divide yourself by stepping round with dividers, which would be quite exact enough for the collar.—F. A. M.

**Steel Spring.**—H. S. (*Chesterfield*).—Your order is a difficult one to fill, especially as you want the springs of different *tempers;* it would have been easier if different *strengths* would have done. I should advise you to write to Messrs. Grimshaw and Baxter, 33 and 35, Goswell Road, London, E.C. I think clock spring will be the best material to use.—F. C.

**Hinge.**—HELPLESS.—To obtain what you require, you must make or get a spiral spring, which in its length makes one half turn, and in radius fitted to that of the hinge when closed, or it should be rather less, to keep the hinge sides tightly closed. If there is no cavity behind the hinge for the spring to play in, the hinge itself must be recessed. The spring so made is to be firmly fixed by one end to one wing of the spring (the fixed wing preferably), and so set that its free end, after making a half turn, bears firmly against the other wing of the hinge.—F. C.

**Wood Background for Carved Panels.**—B. A. B. (*Hampstead*).—To obtain the basket-work effect, a punch of this style is sold ||| for hammering the uncarved background. Also, I believe, a triangular one ///. But it is obvious that either of these would yield a set mechanical effect, whereas if an ordinary tool—say, a chisel with a blunt edge—is hammered on (in the rougher way shown in the design), the effect can be obtained more roughly, and, therefore, more effectively.—J. G.-W.

**Piano Scale, and Felt on Hammers.**—G. T. (*Chatham*).—Your letter is not very explicit. I gather from it that you, having set your compasses to $\frac{5}{16}$ of an inch, 9 in. and 3 ft. 11 in. do not correspond. I cannot understand exactly what you want to know; so I must surmise. In No. 36 of WORK you will find a portion of a scale, actual size. Now, if you make one octave correct to this, and repeat it until you have the seven octaves, I cannot see how you can go wrong; this will be your top scale, the bottom one is contracted 2 in. at the bass end. The top scale is placed at the bottom edge of the wrest-plank when it is used, as this is the strike-line where the hammers strike. If you placed this scale on the top edge of wrest-plank, it would be decidedly wrong. Read No. 36 of WORK with care; it will explain everything you require to know. Of course, if you commenced your piano before you saw WORK, it is impossible for me to know how you made it, and where you obtained your instructions, unless you divulge it. If this answer does not satisfy you, write again and enter into particulars. The longer the letter, the more complete will be the answer. The felt, as you are perhaps aware, is manufactured on the taper; the thick end is placed at the bass, while the thin end extends to the treble. You can obtain this felt in strips—from 1s. 6d. upwards—from Goddard, ironmonger, etc., Tottenham Court Road, W.C. Of course, the better the quality, the better the tone; you can get a medium quality for 3s. 6d. You require a long-bladed shoemaker's knife, and sharpen on emery cloths; this gives an edge suitable for felt. Take the felt off your treble and bass hammer, and see that your felt is not too wide. If you look at the felt you have taken off, you will see that where it is glued on the wood of the hammer the edges are pared down while it is in the length. Now make a piece of wood $\frac{1}{16}$ of an inch wider than the felt you have taken off. Use this as a gauge to cut your felt by. Springs for putting this felt on may be obtained from G. Buck, tool-maker, Tottenham Court Road, if I remember rightly, at about 3d. each. If you wish to do without springs, you can use pieces of very narrow tape to tie with. To take the old felt off, cut through the centre of the felt with your knife, as it is not glued here; then you can tear it off. Having your glue nice and hot, but not so thin that it will soak in the felt, begin at the bass end. Take the first piece of felt, and glue the top side of the hammer only; then wrap your piece of tape round, or put on your spring. Now miss one piece of felt and one hammer, doing every alternate one, till you have got to the treble end; then go back to the bass, and glue those you have missed. The idea of missing every other one gives you more room to put your spring on. Now, having got all these glued on the top side, start at the bass again as before, and glue the under side of the hammer, not the centre. Pull your felt firmly over (you will find it will stretch a little), and secure as before. You must then trim the sides with your knife; and if you have not cut them neatly (as this requires some practice), apply a warm flat-iron to the sides.—T. E.

**Boiler Injector.**—STOKER.—The apparent paradox of steam leaving one part of a boiler, and not only rushing back into it, but carrying a quantity of water with it—although, on its passage, there is an opening to the atmosphere—may be thus explained. It must first be observed that whereas steam in motion expands in *all directions*, a jet of water moves in one direction only. Suppose we have steam 60 lbs. pressure above the atmosphere; its volume is 380 times that of the water from which it came, and into which it will condense. Then, if it is supposed that steam is leaving a boiler at that pressure through an opening of 380 square inches, and that its speed of motion remains the same, if it is suddenly condensed in passage it will pass through an opening of one square inch, it will remain of the same *weight*, and, therefore, have the momentum acquired from 60 lbs. pressure over the larger area, and being liquid will keep its course in its direction when condensed; so it is easy to see why the condensed steam will jump a break and go back into the boiler, and it is also evident that it will have a great margin of spare energy. Its speed will not increase, for each particle will have its original velocity, but in the condensed form they will close up and act upon less surface—like a few people forming up close together to rush into an open crowd. Now, as for the feed water it takes in, that depends upon the general principle of injectors. If you blow a stream of air through a nozzle into a tube in line with it, its friction against the air through which it passes drags the latter with it and so creates a partial vacuum into which water will flow, and the same occurs with the condensed steam in the boiler injector. This is very old, and a water stream was in remote times so employed to suck in air for a blast at the Cornish mines. If you take a T-shaped piece of glass, open at all ends, and put the stalk in water, and then blow through the horizontal part, you will see the water rise. Barber's sprayers are on this principle.—F. C.

**Oven Thermometer.**—D. G. T. (*Ilminster*).—An oven thermometer should be procurable for about five shillings. Arensberg, Boar Lane, Leeds, or any respectable scientific instrument dealer, would supply you with one.—QUI VIVE.

**Bass Bar.**—ALBERT.—Accepting 9 in. as the width across the waist, the position for the bar should be laid out by making two lines, the first 1 in., the second 1½ in. distant from, but parallel with, the centre joint. The dimensions of the bar—speaking generally, of course—are 21 in. long by ½ in. thick by 1 in. deep at the point where the bridge will stand; from this point it should diminish with a slight curve to ¼ in. deep at each end. The "reeds" of the wood should run vertically through the bar, which ought to be 1½ in. deep when planed up ready for being fitted.—B.

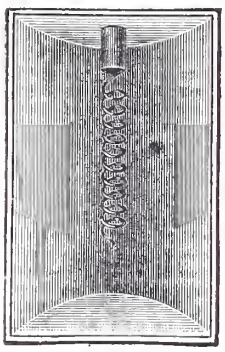
**Fairy Bells.**—CURLY.—The dimensions given on page 814, Vol. I., are correct. No better wood than pine can be used, as it combines lightness with straight, even grain, and a perfect freedom from

knots. The best kind of varnish to use is hard copal. If spirit varnish is used, although it may be handled sooner, it is not nearly so lasting, and will show white marks if scratched or chipped. But better than any varnish is French polish, which also gives a better finish. The figures given in Fig. 3, p. 814, are 2¼ in.—R. F.

**Syphon.**—W. B. (*Highgate Hill*).—The term syphon (although generally employed) is hardly the correct one. It would, perhaps, be more correct to say trap. If your meter is lower than the main, you must put in a T-piece close to the meter. Let the T-piece point downwards, and screw a short piece of barrel (about 12 in. or 18 in.) in it, plugged off at the end. This will catch any water that may collect in the pipes, and can easily be unscrewed and emptied at any time. It will be best to call the attention of the Gas Company's inspector to the fact that a syphon is necessary before putting it in.—T. W.

**Chromic Acid Cell.**—J. A. S. (*Cardiff*).—I cannot understand or explain the erratic behaviour of your chromic acid cells, as I have not experienced such variations as you mention. It would be better to employ a stronger solution, containing 3 ozs. of chromic acid and 3 ozs. of sulphuric acid to 1 pint of water, instead of 1 oz. of each to ½ pint of water. I should suspect a wrong adjustment of the brushes, or a worn condition of their bearing parts, rather than a failure in the cells.—G. E. B.

**Magnesium Lamp.**—DRY PLATE.—One of the most simple and least costly forms of a magnesium lamp is shown in the annexed illustration. It is made of silver-plated sheet copper to the form shown, and the inside is burnished and polished to a mirror-like brightness. The height should be from 6 in. to 7 in., and the width in front about 4 in. A small brass clip is fixed in the roof of the lamp, and to this the spiral of magnesium wire is attached. The spiral is made out of 6 in. of magnesium wire wound on a thin pencil, then stretched out. It is burnt by means of a small spirit lamp. Some few years ago a gentleman advocated in the *British Journal of Photography* the use of granular magnesium mixed with sand instead of magnesium wire. The mixture was held in a small coned funnel of brass over a spirit lamp furnished with a horizontal burner. When all was ready the mixture was released, and the magnesium took fire as it fell through the flame of the spirit lamp. Perhaps some of our photographic friends can suggest a better lamp.—G. E. B.



Magnesium Lamp.

**Booth's Mitre Machine.**—J. F. (*Hyde, Cheshire*).—I should think you could get it from any large tool maker, or from Booth Brothers, Tool Makers, Dublin, Ireland.—R.

**How to Make a Dulcimer.**—TRICHORD.—An article on the above appeared in Nos. 31, 38, and 41 of WORK. The numbers can be had from the publishers, Cassell & Company, London, E.C.; or you can order them through your bookseller.

**Steam Carriages.**—J. W. (*Belfast*).—You would have no difficulty in getting a steam engine fitted to a road carriage. Its weight will depend upon the power required, and that will be ruled by the steepness of the hills you have to ascend. One of Mr. Yarrow's engines, such as he puts in his "Zephyr" yachts, might suit. They are worked with mineral oil vapour instead of water, and mineral oil is the fuel; they are driven from coil boilers. You might write to Messrs. Yarrow & Co., Millwall, London, on the subject. As to a steam engine, you might write to Messrs. Robey & Co., Lincoln; but in each case state just what you want. An electric motor would be cleaner than a steam engine.—F. C.

**Fowls' House.**—E. H. I. (*Norwich*).—The sketches show a portable wooden fowls' house, with nest-boxes and perch inside, so that it can be drawn by a horse into different fields when required. Fig. 1 shows the carcase or framework, with 4 in. by 4 in. sleepers (on which the whole is erected, and to the ends of which the wheels are attached); sills, 4 in. by 3 in.; corner posts, 3 in. by 3 in.; heads, cross-pieces, and intermediate uprights, 2½ in. by 3 in.; joists, 4½ in. by 2 in.; rafters, 2½ in. by 3 in.; ridge board, 1¼ in. by 7 in. All the openings, except those left for the nest-boxes, should have braces going from angle to angle, especially as the structure is going to be subjected to great strain by the motion of moving over rough ground. I have left these braces out in the sketch for the sake of clearness. Fig. 2 shows the thing complete, with the exception of the wheels. These can be got at any large ironmonger's, and are readily fixed to the under side of the 4 in. by 4 in. sleepers. The sides are covered with feather-edge boarding, and the nest-boxes with 1 in. matchboarding. All the woodwork should be yellow. The roof is the ordinary iron roofing. Louvre ventilators should be provided, as shown at each gable, so as to ensure thorough ventilation; and the window is also very desirable. The inside of the hatchway in door should have a sliding or hinged flap to be fastened inside, so that when the door is locked you have the fowls under control. The slope should also be hinged or detachable, to save it from injury in moving. The size and position of perches depend very much on the class and size of fowl you wish to keep, and can easily be added to suit your requirements. If you examine Fig. 1, you will see that the construction is very simple, and can easily be made by anyone who can use a few

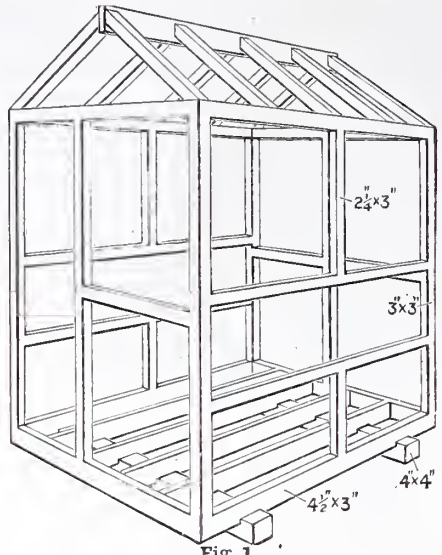


Fig. 1.

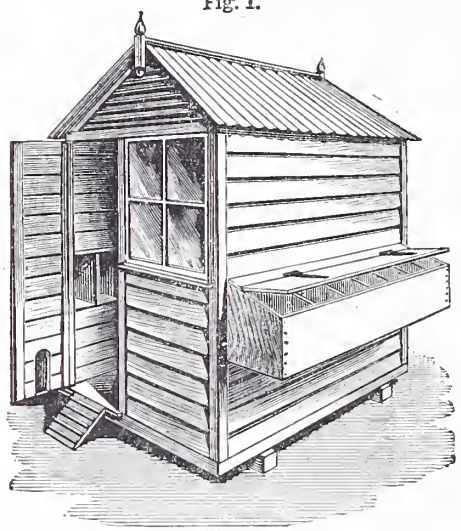

Fig. 2.

Fowls' House. Fig. 1.—Carcase or Framework. Fig. 2.—Fowls' House complete.

simple tools; and most of the joints need only be butted together and strongly nailed. The floor boards should be left loose, to enable the whole to be thoroughly cleansed and lime-whited inside from time to time. I have given the size of house as 6 ft. by 8 ft., so you will see it is rather a large thing for an amateur to attempt. The great advantage of the nest-boxes opening from the outside is, firstly, the convenience of taking eggs without entering the house; and secondly, the nests are kept clean, because it is impossible for the fowls to foul them from the perches above. I am not prepared to state what you would have to pay for materials in Norwich, but the best way would be for you to measure up the quantity of each sort of stuff you require, and go to a respectable timber merchant direct, and ask what he would charge. Write to Messrs. Boulton & Paul, Rose Lane Works, Norwich, asking them for a price.—E. D.

### V.—BRIEF ACKNOWLEDGMENTS.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—ANXIOUS; A. MCC. (*Holywood*); B. and W. (*Sheffield*); INDEBTED; J. S. (*Ipswich*); G. W. (*Bradford*); J. W. M.; DIAPASON; R. O. (*Birmingham*); R. A. D. (*Forest Hill*); W. H., W. E. T. (*Newcastle-on-Tyne*); J. J. (*Lifford*); H. W. (*Strabane*); LEMUR; W. B. B. (*Edinburgh*); W. T. (*Stirling*); B. (*Dundee*); M. E. R. (*London, W.*); A. R. (*Scorrier*); F. S. M. (*United States, America*); HEATHFIELD; D. B. (*Norfolk*); J. W. # FRETWORK FOR AMATEURS OF BOTH SEXES AND ALL AGES.

Eclipse Design, No. 102.

Wall Bracket. Price 6d.

## THE MOST PROFITABLE AND FASCINATING OF ALL HOME PASTIMES. EASILY LEARNT.

J. H. SKINNER & Co. having *Dissolved Partnership*, are offering their *Enormous Stock*, including 250,000 FRETWORK PATTERNS and 100,000 ft. of Solid and Three-Ply FRETWOOD, Veneers, &c.; 1,000 Gross of FRETSAWS, besides an immense quantity of TOOLS, OUTFITS, &c., as a special inducement to their customers to order at once.

**4,500 1s. Books of Fretwork Patterns**, each containing Twelve Large Sheets, beautifully lithographed, none of which would be sold retail at less than 2d., and many at 3d. and 4d. each; also

**1,200 2s. 6d. Books of Fretwork Patterns**, containing Twenty Sheets, 19 in. × 12 in., of new designs, many of which would retail at 6d. each. These Books,

**£375 in Value, will be GIVEN AWAY.**

Amateur customers ordering 5s. worth of designs from Catalogue will be presented with one of the above 1s. Books. Those ordering 10s. worth will receive a 2s. 6d. Book.

**An Allowance of 10 per Cent.** *in goods* will be made on all mixed orders for Wood, small Tools, Saw Blades, and Designs, amounting to 10s., and **15 per Cent.** on orders amounting to 20s. and upwards. NOTE.—*This reduction does not apply to Treadle Machines.*

N.B.—A SPLENDID OPPORTUNITY FOR BEGINNERS.

**Complete Fretwork Outfit**, comprising 12-inch Steel Frame, Forty-eight Saws, Awl, File, Four Designs (with sufficient Planed Wood and 1s. Handbook on Fretwork). **An Archimedian Drill,** with brass handle and Three Bits, will be **SENT GRATIS** with each Set. Post free for 3s. 6d. Outfits on Card, 1s. 6d. and 2s. 9d., post free. 6 ft. 2nd quality assorted planed Fretwood, 1s. 9d.; post free, 2s. 6d. 12 ft. ditto, ditto, 3s.; post free, 4s. 3d.

**SKATES!!!**—EVERY PAIR WARRANTED.—Sizes, 7½ in. to 12 in. No. 1, Unpolished Beech, 10d. per pair. No. 2, Polished Beech, 1s. 6d. per pair. No. 5, "Acme" pattern, all steel, 3s. per pair. No. 7A, "Caledonia" pattern, self-adjusting, one screw fastening the whole skate, the best principle, 6s. per pair. No. 8, Metal frame, with strap complete, 1s. 9d. per pair; postage, 5d. per pair. These are not rubbish; we warrant every pair.

NEW CATALOGUES of Machines, Designs, Wood, Tools, etc., with 600 Illustrations and full instructions for Fret-cutting, Polishing, and Varnishing, price 4d., post free. A Specimen 6d. Fretwork Design **SENT GRATIS** with each Catalogue; also a List of Designs, Outfits, Tool Chests, etc., at Greatly Reduced Prices to clear.

N.B.—All orders *must* be accompanied by remittance. APPLY—

*Beecham's Pills* *Beecham's Pills* *Beecham's Pills* *Beecham's Pills* *Beecham's Pills* *Beecham's Pills* *Beecham's Pills* *Beecham's Pills* *Beecham's Pills* *Beecham's Pills* *Beecham's Pills* *Beecham's Pills* *Beecham's Pills* *Beecham's Pills*

ARE universally admitted to be worth a Guinea a Box for Bilious and Nervous Disorders, such as Wind and Pain in the Stomach, Sick Headache, Giddiness, Fulness and Swelling after Meals, Dizziness and Drowsiness, Cold Chills, Flushings of Heat, Loss of Appetite, Shortness of Breath, Costiveness, Scurvy and Blotches on the Skin, Disturbed Sleep, Frightful Dreams, and all Nervous and Trembling Sensations, &c. The first dose will give relief in twenty minutes. Every sufferer is earnestly invited to try one Box of these Pills, and they will be acknowledged to be

## WORTH A GUINEA A BOX.

For Females of all ages these Pills are invaluable, as a few doses of them carry off all humours, and bring about all that is required. No female should be without them. There is no medicine to be found equal to Beecham's Pills for removing any obstruction or irregularity of the system. If taken according to the directions given with each box, they will soon restore females of all ages to sound and robust health. This has been proved by thousands who have tried them, and found the benefits which are ensured by their use.

For a Weak Stomach, Impaired Digestion, and all Disorders of the Liver, they act like magic, and a few doses will be found to work wonders on the most important organs in the human machine. They strengthen the whole muscular system, restore the long-lost complexion, bring back the keen edge of appetite, and arouse into action with the rosebud of health the whole physical energy of the human frame. These are FACTS testified continually by members of all classes of society, and one of the best guarantees to the Nervous and Debilitated is, BEECHAM'S PILLS *have the largest Sale of any Patent Medicine in the World.*

## Beecham's Magic Cough Pills.

As a Remedy for Coughs in general, Asthma, Bronchial Affections, Hoarseness, Shortness of Breath, Tightness and Oppression of the Chest, Wheezing, &c., these Pills stand unrivalled. They are the best ever offered to the public, and will speedily remove that sense of oppression and difficulty of breathing which nightly deprive the patient of rest. Let any person give BEECHAM'S COUGH PILLS a trial, and the most violent Cough will in a short time be removed.

Prepared only, and sold Wholesale and Retail, by the Proprietor, THOMAS BEECHAM, ST. HELEN'S, LANCASHIRE, in Boxes, 9½d., 1s. 1½d., and 2s. 9d. each.

Sold by all Druggists and Patent Medicine Dealers everywhere. *N.B.—Full Directions are given with each Box.*

## KNOTTING, SsplicING, AND WORKING CORDAGE.

BY LANCELOT L. HASLOPE.

### Simple Knots and Knots for Uniting Ropes.

Overhand Knot—Fourfold Knot—Figure-of-Eight Knot—Reef Knot—Granny Knot—Rosette Knot or Bow—Openhand Knot—Weaver's Knot—Overhand Knot joining Two Ropes—Flemish Knot joining Two Ropes—Whipcord Knot—Fisherman's Knot.

*Simple Knots.*—Overhand knot (Fig. 1). This is the simplest knot that is made; at the same time it is a very useful one. It also forms a part of many other knots. To make it, the standing part of the rope—that is, the main part in opposition to the end—is held in the left hand, and the end of the rope is passed back over it (whence its name) and put through the loop thus formed. It is often used at the end of a rope to prevent the strands unlaying. It is also sometimes used in the middle of a rope as a stopper knot. If we pass the end of the rope through the bight two, three, or more times before hauling it taut, we then have the double, treble, or fourfold knot (Fig. 2). This forms a larger knot than Fig. 1. It is often used on the thongs of whips, and is then termed a blood knot. Fig. 2*a* shows the knot hauled taut. Fig. 1 also goes by the name of the Staffordshire knot, as it forms the insignia of the county. A Flemish or figure-of-eight knot is shown in Fig. 3. To make it, pass the end of the rope back, over, and round the standing part, and up through the first bight. For the benefit of my non-nautical readers, I may say here that the bight of a rope is the loop formed when a rope is bent back on itself, in contradistinction to the ends. The term is also used for the bend in the shore forming a bay—as the Bight of Benin. The Flemish knot is used for much the same purposes as the preceding knots, but is rather more ornamental.

*Knots for Uniting Ropes.*—The circumstances under which we have to join the ends of two pieces of cordage together are very various, and several methods of doing so are brought into requisition at different times, but it is always of considerable importance that the most suitable knot be employed in each case. The value of some knots consists in the rapidity with which they can be made, and in the case of others in the readiness with which they can be undone, but it is a *sine quâ non* that the knot should hold firmly and not slip when once hauled taut. The commonest knot for joining the ends of two ropes, and probably the knot that is most often made, is the sailor's, true, or reef knot (Figs. 4 and 5). When correctly made it is as perfect as a knot can be. It can be made very rapidly and undone with equal ease, and is very secure when taut. It has, however, one disadvantage—it will not answer when made with ropes of different sizes, as it then slips and comes adrift, but where the

two pieces of cordage are of the same size it is a most secure and reliable knot, the strain on every part being so equally distributed. Though very readily made when once you get in the way of it, it requires a little practice to make it properly. To do this, take an end in each hand and lay one over the other, the right end being undermost; bring the left-hand end under the standing part of the right end, as shown at A, Fig. 5, and over the end at B, round it, and up through the bight at C. The key to the knot I take to be putting the right end under the left when the two ends are crossed at the commencement of the knot, as the left-hand end then comes naturally first over and then round the other rope, and the ends lie parallel with the standing parts, as in Fig. 4. If the ends are not passed correctly, a granny, lubber's, or calf knot results. This is shown in Fig. 6. Though at first sight this seems to be a good knot, yet it is not so in reality, and when any strain comes upon it it slips and becomes useless. Fig. 7 is a granny knot, as it appears when hauled upon. It is considered a very lubberly thing to make a granny knot, and my readers should practise until they can make a true knot rapidly and with certainty in any position. The sailor's knot is invariably used for reefing sails, the ease with which it can be undone making it very valuable for this purpose. You have only to take hold of the two parts on each side just outside the knot and bring the hands together, and the loops slip over one another, as in Fig. 4, and the knot can be opened at once. This knot has a curious peculiarity which I do not think is generally known. If we take hold of the end of one of the ropes in one hand and the standing part of the same rope in the other, and haul upon them until the rope is straight, the knot becomes dislocated, so to speak, and the rope not hauled upon forms a hitch (Fig. 4*a*) round the other part. This property was the secret of Hermann's celebrated trick, "the knotted handkerchiefs." After the handkerchiefs were returned to him by the audience knotted together at the corners, under pretence of tightening the knots still more, he treated each knot as I have described. To the superficial observer the knots seemed as firm as ever, but in reality they were loosened so that a touch with his wand separated them easily. The common bow or rosette knot is a modification of the sailor's knot. The first part of the process of making it is the same, but instead of passing one end singly over and under the other, as in the sailor's knot, both ends are bent back on themselves, and the double parts worked as before. Care must be taken to pass these doubled ends exactly as those described in the sailor's knot, or a granny bow will result. One often hears people say that they cannot understand *why* their shoes are always coming untied, the reason being that they were tied with granny instead of true bows. Another way of joining the ends of two pieces of cordage is shown in Fig. 8. This is merely an overhand knot, made with two ropes instead of one. It is also sometimes called an open-hand knot. It can be made very quickly, and there is no fear of its slipping, but if there is much strain put upon it the rope is very apt to part at the knot, in consequence of the short "nip," or turn, that it makes just as it enters the knot.

Fig. 9 shows the weaver's knot partly made, and Fig. 10 the same knot completed, but not hauled taut. This knot is called by weavers the "thumb knot," as it is made over the thumb of the left hand, and is used by them in joining their "ends" as they break. No one would believe, without seeing them, the rapidity with which they make the knot, snip the ends off, and set the loom going again. It is used by netters to join their twine. It also forms the mesh of the netting itself, though, of course, it is then made in a very different way. In making the weaver's knot, we cross the two ends to be joined in the same way as in the sailor's knot, placing the right end under, and holding them with the thumb and finger of the left hand at the place where they cross. The standing part of the right-hand rope is then brought back over the thumb and between the two ends, as shown in Fig. 9. The end A is then bent down over it, and held with the left thumb, while the knot is completed by hauling on B. We shall meet with this knot again further on.

Fig. 11 shows an excellent way of joining two ropes. It can be made by laying the ends alongside one another, overlapping each other sufficiently to give room for the knot to be made. The double parts are then grasped in each hand and an overhand knot is formed, which is made taut by hauling on both parts at once, as if the knot was single. Though this is the easiest way to make the knot, it is not available where the ropes are fast. In this case we make a simple knot on the end of one rope, but do not draw it taut. The end of the other rope is then passed through the bight of the first, and a second loop formed with it alongside the first. The knot is closed by drawing the two ropes as before. This is in every way an excellent knot, and very secure. Fig. 12 shows the ends of two ropes joined by means of a Flemish knot.

This does not require much description. It is made after the manner of the last knot.

Fig. 13 is the whipcord knot, and is used to fasten the lash to a whip; A shows the thong, and B the lash. The lash is first laid across the ends of the thong, which are turned up over it. The lash is then brought completely round the thong and through the loop it makes, which secures the ends of the thong firmly. If a silk lash is used, the short end is cut off, but if whipcord, the two ends are generally twisted together for a few inches, as at B, and an overhand knot made with one end round the other, which secures them. The remaining part is left somewhat longer, and another overhand knot at the end prevents it from unravelling.

The fisherman's knot (Fig. 14) is one of the most useful knots we have. It derives its name from the fact that it is always used for joining silkworm gut for fishing purposes. In making it, the strands are first laid overlapping one another, and an overhand knot made with one end round the other strand. The strands are then turned round, and another overhand knot made with the other end round the first strand. When the knot is tightened by hauling on the standing parts, one knot jambs against the other and holds securely. The knot is improved by putting the ends twice through their respective loops, as in Fig. 2. The size of the knot is increased by this means, but it will stand a much heavier strain, so that it is advisable to do this whenever the size of the knot is not of paramount importance.

The attention of the reader is called to the illustrations of the various knots mentioned above, which show in the clearest manner possible the nature and character of each knot, and how it is made

# ARTISTIC LITHOGRAPHY.

BY A. J. ABRAHAM.

## Materials.

THE INK—ITS PREPARATION—MIXING THE INK—CHALKS—STUMPING CHALK—EFFECT OF HEAT ON CHALKS—CRAYON-HOLDERS—BRUSHES—HANDLE—CARE OF BRUSHES—DUSTING BRUSHES—LITHOGRAPHIC PENS—INSTRUMENTS.

*The Ink.*—After the student is satisfied that the stone is in a suitable condition for working upon, his next consideration is the materials used in the manipulation of the work, the most important and principal one being the fatty matter which is necessary to preserve the natural qualities of the stone, and with which the drawing must be made. This consists of a black ink, and is sold at all lithographic dealers in two forms, that of a solid stick of ink, and chalk.

Being unnecessary for the student to make his own ink, it will be sufficient for him to know that it is composed of certain fatty matters, such as soap, tallow, shellac, etc., mixed in various proportions, and a black pigment in sufficient quantity to allow the artist to see how his work is progressing, and also how the subject will appear when printed in black. Without this black pigment the drawing would be invisible on the stone, although it would print just the same.

*Its Preparation.*—When the ink is required for use it must be dissolved in soft water, and should be made fresh every day, for if allowed to stand from one day to another, it would get thick, and more water require to be added, in consequence of which the ink would not contain sufficient fatty matter in proportion to the water used for preserving the stone, especially in any very fine work.

*Mixing the Ink.*—The best way of mixing the ink is to warm a small earthenware saucer, cut some small pieces from the ink, and pour sufficient water from a drop-bottle, or one with a small hole cut in the cork, over it to make enough for the day, then rub with the fingers in order to dissolve the ink, until it be of the necessary consistency for working, which will be when the ink adheres to the side of the saucer. Should there be too much water, the ink will glide off, besides which it will not contain sufficient greasy matter as spoken of above; and if made too thick, it will not flow freely enough from the pen, or brush. It should be just thin enough not to spread when working with it on the stone, and just thick enough not to smear when dry.

When working with the brush it is best to use a saucer slightly tilted, but when the pen is used a small bottle is better. A large thimble makes an excellent substitute, and a very good inkstand can be made by taking a small square block of wood and cutting a hole in the centre, large enough in which to place the thimble. Any small bottle would do as well so that it is washed out every day, but the above is, perhaps, as good as anything.

*Chalks.*—These should be sharpened by cutting away from the point in the same manner as charcoal or an ordinary crayon; being of such a soft, greasy substance, it is very likely to break. The ordinary crayon-holder is rather heavy for lithographic chalks, and likely to make them snap. It is preferable to use a holder consisting of a wooden handle with a steel top enclosed by the usual ring for holding the chalk. This allows the slightest pressure required on the stone to be given entirely by the hand, instead of by any weight from the holder itself.

These chalks are made of various density and numbered, the hardest being a copal chalk, which should only be used for outlining very fine clear lines that cannot be made with a No. 1 chalk, which, being the next in order, is also used for outlining and fine tinting generally. No. 2 is a medium chalk, and No. 3 being very soft, is useful for strong shadows and large bold work.

*Stumping Chalk.*—This is not much used except in light even tints for large work, as by its very density it prints stronger than the ordinary numbers, besides which it works very flat and without any texture. It should be used with the stump or a piece of chamois leather.

A good way to use this is to keep a small piece of stone handy with an average grain, and rub a piece of the chalk across or down one side until it is quite black. Then with a small clean pieee of the leather passed over the first finger of the right hand and held firmly, take some of the chalk from the stone, being careful only to rub it one way, and taking it off as evenly as possible; then try it on another part of the stone (always taking care to rub one way) to see the necessary strength required, to take off any superfluous chalk that may have adhered to the leather, and also to make it more even, or it will be likely to work in streaks. The stump or leather being now ready for working with, gum round the edges of the space required for the tint, and when perfectly dry rub the leather evenly over the surface, and the gum will prevent the chalk from adhering to the stone further than it is required. It sounds very easy just to rub an even tint on the stone, but the novice will find it requires practice to obtain an equal pressure of the finger on a surface of only a few square inches.

The student will also find on trial that it is impossible to make a chalk drawing on a polished stone, on account of the even surfaee not allowing the chalk to be scraped away, which is done in the case of a grained stone.

*Effect of Heat on Chalks.*—Heat has a great influence on the chalk, it being often possible to get the same effect with a No. 1 on a hot day in summer as by the use of a No. 3 on a cold day in winter. It is also advisable to have half a dozen chalks in use at the same time, as they are apt to get soft from the heat of the hand, and therefore will not work well.

*Crayon-Holders.*—The artist should have different coloured crayon-holders, so as to easily distinguish the number of the chalk he is using, and he need never throw away the chalk cuttings, for although they are of no use to him, still they make excellent ink for the printer, and a good foreman will be very glad of the perquisite.

*Brushes.*—The brushes used should be very fine red sable, and for fine line work it is much better that the artist should cut away the outside hairs from an ordinary size lithographic brush, leaving only the centre ones for working with, than to buy one the exact size required, which would not be as firm as a larger brush cut down.

Some writers use a brush with the hairs 1 in. long, but as they require very careful manipulation, it would not be advisable for the student to practise with them at first.

Brushes that will not always do for one thing come in very handy at times for a different object; thus a brush that has lost its point, and cannot be used any longer for drawing fine lines, may be very well used for filling in solid—that is, where a portion of the stone is required to be covered with ink, and brushes that are of no further use for ink are often suitable for gum work, but the student must be most careful in keeping the latter apart from those used for ink, as gum aets as a protection against the ink touching the stone, and, therefore, no work would print if drawn with the same brush as that used for gum, or if drawn on any part of the stone where gum has been used.

*Handle.*—A good handle for brushes can be obtained by using a common metal pocket penholder, in which the top can be taken off and reversed to protect the pen, or in this instance the brush, which should be fixed in with sealing-wax, of course not allowing any of the wax to go on the outside of the metal, as it would not then shut in the holder securely.

*Care of Brushes.*—Always wash the brush with a little soap and water when finished with it for the day. Some artists allow the ink to dry in the brush as a protection to the point, but it is a very dirty habit to get into, as the brush must always be washed before using, and it is much easier to do so the same day than if it were allowed to dry with the ink in it, and most people will agree that there is nothing so annoying as to find dirty tools when they are ready and anxious to start work.

*Dusting Brushes.*—The artist also requires a flat camel's-hair brush, about 2 in. in width, for dusting the stone with during the progress of the work, it being most necessary that the stone should be kept perfectly free from any specks of dust, or dirt, etc. This applies specially to chalk work, and is of so much importance that it will be referred to again when the work is explained.

A flat camel's-hair brush of not less than 4 in. in width is required for etching purposes, and should be kept when not in use in a well, similar to those used for copying brushes. It is better to have one that will hang against the wall, and only use sufficient water to cover the hair of the brush, or else the water, in conjunction with the acid used, will rot the metal of the brush.

*Lithographic Pens.*—Lithographic pens are much finer and more delicate, besides being more highly tempered, than the ordinary writing pens, and being very brittle are apt to snap unless carefully handled; in fact, an ordinary pen for fine work on stone is of no use whatever, on account of the difference in the substance of the ink, and the writing or drawing surface, but lithographic pens are so common that they can be obtained from most dealers besides those who deal exclusively in lithographic materials; they therefore need not be further described.

The artist should have several pens in use at the same time, for if one will not work well another will, so he can change about, and frequently a pen that is difficult to manage one day will work splendidly the next. New pens are better for the finer parts of the work, and worn ones for the coarser; and if the pen should get crossed nibbed, which is often the case, all the artist need do is to bend it back on the thumb-nail, when it will work as well as before—that is, presuming it has not snapped during the operation; but the student will soon judge for himself the pliability of the pens.

The artist should always use a good size penholder, and not merely a thin stick of wood, else the hand is apt to get cramped unless there is something firm for it to grasp, besides which the artist will work with much greater freedom; and this applies equally well to crayon and brush-holders.

*Instruments.*—Such instruments as the bow compasses, and ruling pens, are very highly tempered, and are specially made for drawing on stone; they should *not*, if possible, be used for drawing on paper, as it spoils them for stone work, and they should be kept in wadding, or chamois leather cases.

Rulers, straight-edges, eurves, set-squares, etc., should be made of the best materials, for the stone being perfectly level, and having such a polished surface, enhanees the slightest error, which on paper is sometimes toned by its roughness. Steel is a very good metal, and although the student will find it rather more expensive, still, once having invested in steel instruments, he will find them invaluable, and will seldom, if ever, have to buy others; the same cannot be said of wooden ones.

It is presumed that the student already has a knowledge of drawing, and therefore a necessary knowledge of the above instruments and also their use; they are not therefore further described.

In the next paper I hope to finish with the description of the principal various tools, etc., used in lithography, and I shall then be able to at once take up the more interesting subject of drawing on the stone.

## SOME MORE HINTS ON FRAMING.

BY B. A. BAXTER.

CUTTING TENONS—CUTTING SHOULDERS—TENONS OFTEN TOO WIDE—WEDGES OFTEN TOO GREAT AN ANGLE—CARE IN FITTING PANELS—IN PUTTING TOGETHER—MITRES TO MOULDINGS—SCRIBING MOULDINGS.

IN former papers on Woodwork, in pages 482 and 646, Vol. I. of WORK, I have chiefly confined my attention to the plane. This tool, however, though very important, and its efficient use difficult to the beginner, is not the only tool upon which it is desirable to give some explanation or assistanee.

Supposing that the previous remarks made by the above-signed have been read and understood, and that the verbal description has been translated into "something accomplished, something done," let us now try to finish our framing, which was prepared, set out, and was being mortised. Mortises involve tenons, and it by no means follows that our readers who have profited by the various instructions and advice as to mortises are much helped thereby in the cutting of a tenon. We will, as a preliminary, first examine the mortise-gauge. This we have new and bright, with its lacquer still intact and its polish odorous with benzoin. If so, take care. The steel points of a new mortise-gauge are large and prominent—very tusks, rather than teeth—and our beginners must handle the gauge with care, not using much pressure to score the lines deeply on styles and rails, beeause, if so, we cannot be sure of the exact line which lies somewhere in that deep ugly score. We who deal with pencil marks and chalk lines are too apt to forget the difference between our lines, so-called, and the "flowing of points," the "length without breadth" of the mathematician.

However, let us make as narrow a mark as possible—just enough for us to see and to cut by. In setting the gauge to the width of the chisel, let us be as exaet as we can, and until proficient let us always take the precaution to try the effect on a piece of spare wood, applying the chisel to make sure that we have successfully fixed the points the exact distanee apart.

Now, if the mortise is well cut, it will be just the width of the chisel; but it will *not* be well cut if the gauge is set too wide or too narrow. The two gauge lines will be two conflicting masters, and, inexperienced as we are, we shall fail of a good result.

It will not help the fit of the tenon for the mortise to be cut badly. We will suppose ourselves interested spectators while a workman cuts a tenon. He has already marked with a mortise-gauge the lines which are to form the boundary in thickness—equal, as we have seen, to the width of the chisel—and he has also marked the shoulders each side. We notice that he has marked these with a knife or chisel, and not with a pencil, from which we learn that the appearance of the work is worthy of consideration. We notice that he fixes the rail in the bench screw, and, just placing his thumb on the end of the rail, he draws his saw towards him; and, on inspection, we find that the saw has already made a shallow channel for itself just on the edge of the line,

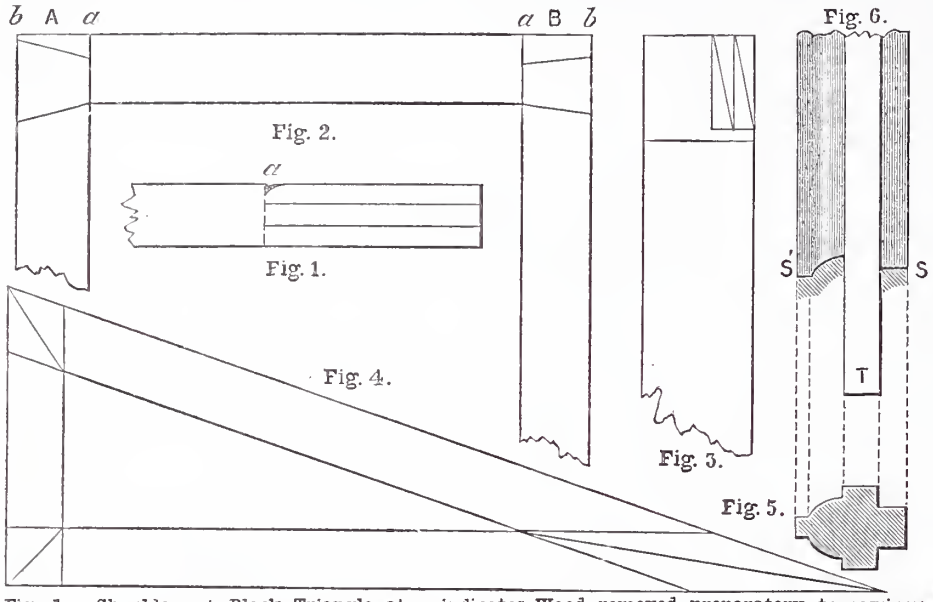

**Fig. 1.—Shoulder-cut Black Triangle at *a* indicates Wood removed preparatory to sawing: slightly exaggerated. Fig. 2.—Diagram showing Difference in setting out Tenons and Wedges—A, injudicious; B, much better: not at all exaggerated. Fig. 3.—Tenon formed at End of Rail, showing Method of cutting Wedges. Fig. 4.—Simple Plan to obtain Mitres: Draw Parallel Lines equidistant from Inner Edge of Frame; join Intersections and Angles of Frame. Fig. 5.—Section of a Sash Bar. Fig. 6.—Diagram exhibiting Scribed End of Sash Bar—S, S, Shoulders; T, Tenon. None of these Diagrams are drawn to Scale.**

the channel itself being outside the thickness of the desired tenon.

We see, too, that he began the tenon at the point farthest from him, accurately to the line, and that he gradually brought the cut to the nearer edge, until, with the same accuracy, one edge of the saw just seemed to scrape the fine line made by the mortise-gauge. Asking him how to manage tenons on long pieces, he tells us that sometimes tenons must be cut on the stools, turning the wood once or twice during the progress of the work. In order to cut tenons successfully, therefore, we must learn the difference between cutting *on* a line and cutting *up to* a line.

Still another point: the saw must not be allowed to penetrate past the shoulder, if the appearance of the work matters at all.

The tenons having been sawn, the shoulders may be cut—removing what are called the cheeks. This is done with the tenon saw, unless in very small work, when the dovetail saw is more suitable. Having the shoulders marked with a knife, we may be allowed to remove a little wood from outside the line, as in Fig. 1.

The line of entrance of the saw is more correctly determined by so doing, and if properly sawn, the joint at the surface is a knife-cut one, as correct as our square or bevel, modified by our skill in using it.

It is most important to exercise care in cutting shoulders that the saw is not allowed to cut too deep, as the tenon would be spoilt by so doing.

I have already said that the proportions of a tenon and its mortise partly depend on what panels, mouldings, rebates, etc., are present; but we ought not to go far from the usual custom of making the tenon about one-third of the thickness of the stuff. As far as the other dimensions are concerned, clearly a tenon right through must be as long as the style is wide; in width, however, we may use judgment.

The present writer has often seen professed workmen make the tenon so wide, that when the work was wedged up and the superfluous wood of the styles cut off, the tenon looked dangerously near the extremity of the style, and the wedge looked like forcing the little piece of wood which retained it right away (Fig. 2).

This leads to the subject of wedges, about which a word or two might be spoken. Our experienced readers are asked to pardon the writer because he wishes to insist on a point so obvious to them. A thick, rapidly increasing wedge does more harm than good, and a young carpenter might do much worse than consult a lathe-man as to the angles which *jam* and those which do not. He will be told that if you want a wedge to hold, like a drill in its socket, the taper must be slight and gradual; while if you want freedom of motion, only obtaining definiteness of position, the magnitude of the angle must be increased.

Wedges, however, as we understand them—of wood, and used for framing—are compressible, and if the tapering receptacle is not cut to the same angle as the tapering wedge placed in it, the compression at the point and the head of the wedge is unequal.

It would, perhaps, be best to have the compression equal, but it would be better to have the compression greater in the interior of the mortise than at the outer edge (at *a* rather than *b*; see Fig. 2).

There is no doubt that this error proceeds from school teaching, in which diagrams of the inclined plane and the wedge are drawn, the wedge generally with an angle about double that of the inclined plane. I distinctly remember being informed (?) that a wedge is really *two* inclined planes fixed together, and my contention that I could see no real difference (as drawn for the boys' instruction) between them, except that the wedge was drawn as an isosceles triangle and the inclined plane was drawn as a right-angled one, the angle opposite the shorter side not being very seriously different in each case. Improved wall-sheets and better illustrations have changed all that.*

However that may be, wedges need not be short and rapidly tapering; but they are still wedges—and are more efficient ones too—if more gradual in the taper.

The wedges for our purpose are usually cut out of the waste wood of the width of the tenon, by which means they are, at any rate, the right thickness. Fig. 3 gives an idea of what I mean.

Panels are often an embarrassment to the beginner—it is so easy to make them other than flat, square, and parallel (by square, the workman means that the angles are right angles).

It is also easy to make the grooves for the reception of the panels the right depth in most places, and yet leave some part of the groove not down to the depth intended.

For each of these faults, greater care is the only and sufficient remedy; and, as practice makes perfect, so the necessity of care only seems to make itself understood when some failure occurs, or, if not actually occurring, its likelihood is pointed out.

That is just the reason why I have called attention to these matters, which, though trifles in themselves, yet are no trifle if they prevent the work from going together as it ought.

In gluing up the framing, we ought not to insert the wedges until the shoulders are in contact, or very nearly so, and wedges ought not in any case to be driven hard—so hard as to smash them—as may be sometimes seen, even in the work of those who ought to know better. Every blow of the hammer ought to be delivered with judgment, otherwise the joints are apt to go up at one corner of each, instead of uniformly, as they ought.

The directions given in my last paper as to setting out the styles may prove useful for gluing up. As may be remembered, the worker was advised to mark out on the edge of the style the outline of the section of the rail; and if the mortise has been truly cut and the tenon just easy, the wedges will give that slight adjustment which will be

* I think not. Theoretically, the teaching was, and is, right enough. The positions of the wedge and inclined plane are altogether different. The inclined plane proceeds from a point in, and is inclined to, a *horizontal* line, supposing, for illustration's sake, that the plane is viewed in side elevation or profile. A wedge, mathematically speaking, under the same conditions is formed by two planes proceeding from the same point in, and inclined at equal angles to, a *vertical* line. Therefore, the surfaces of a wedge *are* two inclined planes, nothing more and nothing less. Moreover, the wedge of Mr. Baxter's schoolboy recollection was a mechanical power shown in its best form for splitting and rending, while the wedge of his later experiences is, or ought to be, cut to suit a certain inclination, and is rather a half wedge—the wedge being divided in the vertical line—used for purposes of locking up, gripping, and compression, and not for splitting.—Ed.

sufficient to bring the rail to the exact place indicated by the setting out.

If, as we are supposing, our framing has any mouldings, a word or two on mitres will fitly conclude this paper. Mouldings, to be perfect, ought to intersect, by which is meant that perfect meeting of edges, angles, and curves which makes it evident that their section is alike; or that, if "raking," the section is properly modified, and that the angles at which the moulding is cut are the correct angles. Let us suppose the angles at the corners of our framing are right angles, then the mitres, or angles at which the mouldings are cut, must be 45°. The angles of intersection are very easily drawn on a panelled framing which has mouldings inserted afterwards, as is often the case. All that is needed is a small piece of wood for a gauge, and, moving it round the panels with a pencil in contact, the place of the moulding can be outlined, and by joining the intersections the correct mitre of each angle, however different, will be obtained. (See Fig. 4.)

In ordinary cases, where the angles are (in workshop phraseology) square, the use of a template for all stuck mouldings is all that is necessary. For mouldings that, instead of being mitred, are scribed—as sashes—the use of the template to indicate the portion to be cut away is similar to its use in mitreing, except that in this case only one of the surfaces requires treatment.

We will suppose a sash bar is to intersect with the style or rail (Fig. 5). A little consideration will show that it can either be done by mitreing or by scribing—in the case of mitreing, by using the template as a pattern to cut off the angles to the point of contact at the edge on both bar and rail; in the case of scribing, using the template only on the bar, as an indication of the portion to be cut away, being the counterpart of the moulding on the rail which remains intact. The learner may see from this that mitres require only to be cut at the proper angle, while a scribe requires the use of chisels and gauges of suitable sizes and curvature, according to the style and contour of the moulding.

On the other hand, scribing has the great advantage of allowing some adjustment. For instance, if the bar just mentioned happened to be a trifle thicker or thinner than its fellow by which the rail was set out, if scribed the fit would be equally perfect; whereas, if mitred, every divergence from the size marked on the rail would be unpleasantly apparent.

Leaving our friends to try some experiments in mitres, scribes, and other joinings, and strongly advising them to spend a little time in such practice, I can only hope—what is sure to be the case—that their success will be in accordance with their industry and perseverance.

## SCREWS USED IN METAL WORK.

BY P. B. H.

THEIR USES—WHAT IS A SCREW?—HOW TO OBTAIN A SPIRAL LINE—DESIGN OF V-THREAD—SQUARE THREAD — TRAPEZOIDAL THREAD — CONVENTIONAL METHOD OF SHOWING THREADS—RIGHT- AND LEFT-HANDED SCREWS—HOW TO DRAW A SPIRAL LINE.

ONE of the—or I might, with perfect truth, say the—most useful pieces of mechanism ever invented is the screw in its various forms. It is employed for such an infinite variety of purposes—in some cases having to bear enormous strains, and in others scarcely any. It is used almost universally (the rivet, its great rival, alone excepted) to hold together two or more pieces of the same or varying metals or materials. It is used as a means of imparting motion in gearing, as in the worm and wheel, the worm being simply a fixed screw turning on its axis. A great many presses are worked by, and owe their great power of compressing substances into small bulk to, the screw, which in these machines is subject to great strains. The breech mechanism of our large and small guns, where the strain is likewise enormous, is kept in position by a screw. Then, again, the fine adjustments of the microscope and the almost inappreciable movements of the measuring blocks in the machine for measuring to the 1,000,000th part of an inch owe their minuteness and accuracy to the screw, which in these two cases is subject to a very slight strain. From these few instances it will be seen between what extremes the screw can be usefully employed. Many others could be given, but the reader himself will, no doubt, recall to mind a number.

In this article I shall confine myself solely to the screws used in metal work, not to those employed in wood.

The forms of the threads vary according to the purpose and the material for which they are employed. I shall show later the principal forms of threads, and the method of drawing them, both conventionally and accurately.

Most readers have some idea of a screw or spiral, but there are, no doubt, many who do not know how to define it and how it is obtained. I once saw, in answer to the question, "What is a screw?": "It is a short pitch spiral"; and in answer to "What is a spiral?": "It is a long pitch screw." This definition gives no accurate information to anyone, though almost everybody has some idea, though faint, of what a spiral is, and that "spiral" and "screw" are used by many persons almost synonymously. Yet the above definition is not quite clear, so I shall endeavour to show how to obtain a spiral line practically, which is, I consider, the best method of impressing it on the memory, as it gives you a very simple way of making one yourself.

Take a cylinder, A B C D (Fig. 1), of any convenient size; then take a rectangular piece of paper, E F G H (Fig. 2), the length of which must be exactly equal to the circumference of the cylinder—that is, the points E G must coincide with F H respectively when the sheet is wrapped round the cylinder. Having got this correct, cut off the dotted portion, E G H, of this rectangle. Take the remaining triangle, E F H, and wrap it again round the cylinder, making F H (Fig. 2) parallel with the axis. The points E and F should now coincide at $E^1$ $F^1$, and the line $H^1$ $E^1$ in its winding round the cylinder forms a spiral or screw, the pitch of which is equal to the depth F H. The pitch of a screw or spiral is the distance the thread or line rises during one complete revolution. For instance, if you turn the cylinder once round in the direction of the arrow, meanwhile following the line from $H^1$, it will have gradually risen

from H′ to F′ or E′, which distance, as before stated, is the pitch of the spiral. By increasing or diminishing the line F H (Fig. 2) the pitch is increased or diminished. By this means the pitch can be varied from the smallest fraction of an inch, as in some watch screws, to as much almost as you like, if the body round which it winds is big enough. A good illustration of a long pitch small diameter screw is the egg-whisk, where, by sliding a wooden nut backwards and forwards along a twisted wire shaft, the whisk rotates first in one direction and then in the other. Spiral staircases are the largest pitch screws I can think of. When once the method of obtaining a spiral line is grasped, the student will follow with comparative ease the drawing of screw or spiral threads, as these only consist of combinations of spiral lines.

Unwin defines a screw as "a cylindrical bar on which has been formed a helical projection or thread." These projections, in order to suit the different purposes for which they are intended, are of various shapes, of which the four principal forms are shown in section in Figs. 3, 4, 5, and 6; but the two first only—viz., the V and the square thread—are in very general use. Fig. 3 shows the ordinary V or triangular thread, as used in all English workshops. The use of a common thread was early recognised by our manufacturers to be of the very greatest importance, and as Sir Joseph Whitworth was the first to propose a uniform system of threads, it has received his name. The Americans use a somewhat similar thread, called "the Sellers," after the introducer.

In most books treating on machine design and engineering formula, there are tables giving the pitch or number of threads to the inch for a given diameter of screw.

Fig. 3 shows the method of designing the Whitworth thread. Draw two parallel lines 0·96 of the pitch apart. Set off the pitch on one of these lines, and at the points so obtained form angles of 55°, as shown. Again, draw two parallel lines centrally between the first two, and 0·64 of the pitch apart. The threads where these lines cut them, or one-sixth the depth of the thread, are rounded off at the top and bottom. The rounding off facilitates the cutting of the screw, and renders it less liable to damage.

When these screws are used in conjunction with nuts, they are termed bolts, and one of their drawbacks is that, when tightened in their nuts, as will be seen from the slope of the threads, the greater the force used to screw them up the greater is the tendency to burst the nut.

For wrought-iron pipes a finer pitched screw thread is used, and is known as the gas thread; it does not cut away quite so much of the metal of the tube.

Fig. 4 shows a square thread, and there are, compared with the V thread, so few used that there is no real standard, each screw being designed for its special work; but the pitch is generally twice that of the triangular thread for the same diameter of bolt. In designing it, the pitch is first settled, and this divided by two gives one-half for the thread and one-half for the space, the depth of which is slightly less than one-half—or, say, $\frac{19}{40}$—of the pitch. These square-threaded screws are generally used to transmit motion. The surface of the thread being normal to the axis of the screw, there is with this form of thread no oblique pressure on the nut, as in the preceding (Fig. 3).

Fig. 5 is the same as Fig. 4, only the threads are completely rounded. This screw is employed where it is subject to very rough usage.

Fig. 6 shows a form of screw thread called "trapezoidal," which is used when the screw has to resist a pressure acting in one direction. Here the surface bearing the strain, as in the square thread, is normal to the axis, so that there is likewise no tendency to burst the nut. The method of designing is almost the same as in Fig. 3. Draw a vertical line, and set off thereon the pitch. From each of these divisions draw horizontal and angular lines at 45°. Through the point where the horizontal line from one of the divisions cuts the angular line from the one above it, draw a line parallel to the first one, which will pass through all the inner angles of the teeth. Then, as in Fig. 3, draw two parallel lines, 0·64 of the pitch apart, centrally between the first two lines. These will cut off a portion of the angles, which should be rounded as shown.

Of course, to draw screws accurately in most machine drawings would take up too much time, and it would be almost impossible in some cases, owing to the smallness of the screw. On this account I have drawn Figs. 7, 8, 9, 10, 11, 12, and 13—which show the conventional methods of drawing threads on bolts—of varying size. Figs. 7 and 9 represent the ordinary V-threaded screw, the first (Fig. 7) being delineated by thin parallel, equi-distant, slightly inclined lines. Fig. 9, being larger, shows a short thick line between two fine ones; this gives a much neater appearance to it than if the lines had been the same. Fig. 8 represents a small square-threaded screw, shown by two fine parallel lines for the thread, while the space between the two threads is slightly increased. Figs. 10 and 11 show respectively a single and double square-threaded screw, somewhat larger than Fig. 9, therefore shown in more detail. The threads in these are represented merely by straight lines, but more in detail than in Fig. 8. The method of obtaining the various points from which the lines are drawn will be shown later in the larger scale drawings of how to draw an accurate V and square-threaded screw. Figs. 12 and 13 show respectively double and single V-threaded screws, which are likewise formed by straight lines.

There are, of course, right- and left-handed screws: those I have drawn are all right-handed. A right-handed screw, when turned in the direction of the arrow (Fig. 11), will, if a nut be placed at the end, enter it; a left-handed one would, however, work out. Another simple way of distinguishing between them is: hold the screw vertically opposite you, when if the threads in passing round the body rise from the left-hand side to the right, then the screw is right-handed; if they rise from the right to the left, then the screw is left-handed. The spiral line (Fig. 2) is also right-handed. A good illustration of a right and left-handed screw working together is the adjustable coupling between railway passenger carriages.

Having shown what a screw or spiral is, and how to obtain it—also the various shapes of threads and the conventional way of drawing the same—we now come to the accurate delineation of the threads of a screw, which, however, through want of space in this number, will have to appear later. But as it may, at first sight, seem rather difficult for beginners to grasp the method, on account of the number of construction lines, I will, before closing this paper, show how the simple spiral line H′ E′ (Fig. 1) is drawn.

Divide the pitch H F (Fig. 2) into any even number of equal (in this case eight) parts, numbered 1, 2, 3, etc. Draw horizontal lines through these points, till they cut H E in 1′, 2′, 3′, etc. As H 1 is an eighth of the pitch H F, the line H 1′ is an eighth of H E. It is also true that all horizontal lines, drawn through any of the divisions in the pitch line to cut the diagonal line H E, cut it proportionately to the pitch: for example, the distance H 4 is half the pitch, therefore H 4′ is half the length of H E, the line forming the spiral. Now, the whole of the line H E just completes the circuit of the cylinder while rising the distance H′ F′ (Fig. 1); therefore H 4′, the half of this line, will complete one-half the circuit while rising one-half the distance—that is, one-half the pitch. Therefore, for every eighth of the pitch rise there is an eighth of the line H E wrapped round the cylinder. If, now, we could mark off the points 1′, 2′, 3′, etc., in their respective positions on A B C D (Fig. 1), a line drawn through them would represent the path of the line H′ E′, or the spiral desired. To do this we proceed as follows:

Draw a horizontal line *a e* below the cylinder, and equal to its diameter, as shown (Fig. 1); draw a vertical line *c f g* through the centre of the cylinder, cutting *a e* in *f*. With *f* as centre, and *f a* or *f e* as radius, describe a semi-circle. Divide this semi-circle into four equal parts at *b*, *c*, *d*, *e*—that is, half the number the pitch is divided into. From *a*, *b*, *d*, and *e* set up vertical lines: the lines from *a* and *e* correspond with the sides of the cylinder.

Now, if a complete circle had been drawn below instead of a semi-circle, the vertical construction lines from *b*, *c*, and *d* would have passed through the points of division in the corresponding half; so a semi-circle is all that is necessary for our purpose.

The lower part of the spiral shall commence on the line *c g*, therefore (supposing Figs. 1 and 2 to be in proper relative positions) produce the line H G (Fig. 2) till it cuts *c g* in H′; this will give the starting-point of the spiral, which, in this case, winds upwards to the right: therefore, from *d*, one-eighth of the circumference to the right of *c*, set up a perpendicular, *d i*. Now, as already explained, for every one-eighth of the circumference the spiral travels it rises one-eighth of the pitch: therefore, produce the line 1 1′ till it cuts *d i* in 1″—this gives the first point in the spiral: then produce the line 2 2′ (Fig. 2), till it cuts the side of the cylinder B D—that is, the vertical line from *e*, which is $\frac{1}{4}$ of a revolution from *c*; this gives one more point in the spiral, viz., 2″. Here let me remark that I have drawn the curve from 1″ to 2″ without any intermediate points, as, from continued practice, I know that it takes some such form. For exercise, however, the readers might subdivide the $\frac{1}{8}$ pitch between H 1 and H 2 into any number of convenient parts, so long as they divide the one-eighth part of the circle *d e* into the same number; then set up perpendiculars from them and draw horizontals from the pitch, when extra points would be obtained between 1″ and 2″ to draw the curve more accurately. After passing 2″, the curve commences to wind behind the cylinder.

If the semi-circle *a c e* had been completed, and divided into eight equal parts, the point showing the next division would have been on the vertical line passing through *d*, as before remarked; therefore, to obtain the next point in the spiral, we may make use of this line. We now prolong the line 3 3′ till it cuts *d i* in

3″, three-eighths of the pitch above H″. For the above reason, 4 4′, produced till it cuts *c g*, will give another point, 4″; 5 5′ will cut *b h* in 5″; 6 6′ will cut A C in 6″. The curves joining all these points must be dotted as it winds round the back of the cylinder. To proceed, 7 7′ produced cuts *b h* in 7″; 8 8′, or E, is represented by E′ coinciding with F′. The curve from 6″ to E′ is drawn in full, as it again winds round in the front of the cylinder.

If the readers of this article will thoroughly master the why and wherefore of these proceedings, they will find no difficulty in understanding the remaining portion, which shows how to draw both the V and square-threaded screw, single and double, and which, as before stated, will appear in a future paper.

## A MODEL ELECTRO-MOTOR.

BY GEORGE EDWINSON BONNEY.

Atkinson's Electro-Motor—The Field Magnet Castings—The Armature and its Bearings—The Brush Rocker and Brushes—The Commutator—Winding the Armature—Winding the Field Magnets—Fitting the Parts Together—Testing for Fault in Insulation—A Cheap Galvanometer.

The small electro-motor shown in the accompanying illustration at Fig. 1 is suited to the requirements of amateurs who have a lathe and employ it in turning parts of machines as a hobby, and who have a fancy for making up pretty little machines for bazaars and exhibitions. It is a machine that will look very well indeed when good workmanship is put into the fitting and polishing of the various parts, and its parts will also require some careful fitting to make them run well. When properly made, it will drive a small polishing or dental lathe, or a small fretwork machine, or a small drilling machine, or even a light sewing machine, with a battery power of some three or four quart cells of a chromic acid type, or the equivalent current from any other source. Full sets of castings and all other requisites are supplied at a low price—3s. 6d. for the castings, and from 1s. 9d. to 2s. for the wire—by Mr. H. Atkinson, 137, Stamford Road, Handsworth, Birmingham.

These castings consist of two malleable iron field magnet sets of cores and bridges, as shown at Fig. 2, each measuring $4\frac{1}{4}$ in. in length by $2\frac{1}{2}$ in. in width; one malleable iron casting (Fig. 3) for the armature, measuring $2\frac{1}{8}$ in. in length by $1\frac{3}{8}$ in. in diameter; two gun-metal castings, $1\frac{1}{2}$ in. in diameter (Fig. 4), for ends of the armature; two brass castings of four-legged spiders for the bearings of the spindle; one brass casting of a pulley, $1\frac{1}{2}$ in. by $\frac{9}{16}$ in.; one brass casting of a smaller pulley, 1 in. by $\frac{1}{2}$ in.; two brass end-pieces, $2\frac{9}{16}$ in. by $\frac{3}{4}$ in. (Fig. 5), to form feet for the field magnets; one brass casting for brush rocker, $2\frac{1}{2}$ in. in length (Fig. 6); two brass castings of brush-holders (Fig. 7); two brass castings of set screws (Fig. 8); castings for the brass nuts, brass tube for commutator, and a strip of phosphor bronze for the brushes.

These having been obtained, we will set about fitting and finishing the various parts and putting them together.

*The Field Magnet Castings.*—These, as received from the vendor, will be rough, but not so rough as some I have seen—in fact, these are clean and tolerably smooth, but they will require a few touches with a file to make them fit and have a presentable appearance. All nodules and roughness must first be filed down with a flat bastard file. The channel for the armature must next be smoothed with a half-round file, care being taken not to alter the contour of the arches, nor to more than merely smooth the casting. The corners of the cores should now be rounded a little, to prevent them from cutting into the insulating cover of the wire as this is being wound on. The outsides may now be smoothed and the ends trued to make the whole fit well together. The top casting is a little thicker than the under one. The under field magnet casting will have the two brass feet or holding-down pieces, shown at Fig. 5, fitted under each end, and must therefore have two small holes drilled and tapped under each end to receive two small screwed studs, which pass through the flanges of the brass feet and the ends of the lower field magnet castings into the iron of the top casting, as shown in Fig. 9. Similar small holes for set screws, to hold the feet of the spiders, must also be drilled and tapped in each of the corners of the tunnel arches (as shown at Fig. 9) above and below the tunnel at each end, and round-headed brass studs may be screwed to fit these. Thus prepared, the castings may have a coat of Japan black and be set aside to dry.

*The Armature* is of the Siemens H girder type in one solid casting of malleable soft iron. This must be filed smooth and true at the ends, and the channel also made smooth with a file. The gun-metal end-pieces shown at Fig. 4 will be fitted to the ends of the armature, and these will hold the steel spindles. It will be well, therefore, to take these together. Get two 2 in. lengths of $\frac{1}{4}$ in. steel rod, and turn them down to $\frac{3}{16}$ in., so as to have them true and smooth. Turn the end-pieces smooth, drill a $\frac{3}{16}$ in. hole in the boss of each, and fit one end of each spindle into each boss, then sweat or shrink them in, as may be deemed best. The end-pieces will be secured to the ends of the armature, after being fitted true to it, by small brass studs; holes must therefore be drilled through the end-pieces and into the armature to receive them. The castings are marked with dots where these holes should be drilled. In one of the end-pieces we must drill two extra holes for the ends of the armature coil to come through, and these holes must be bushed with small tubes of ivory or of bone. When the ends are fitted on, mount the armature in a lathe, and true it by taking a very light cut over it, just enough to take off the rough skin. This done, mark all the screws and screw holes to act as guides in putting together, take off the ends, and dress the web and channel with shellac or good sealing-wax varnish, then set aside to dry, ready for winding.

The brass spindles, shown at Fig. 1, fulfil the double purpose of clamps to hold the field magnets together and to form bearings for the armature spindles. These must now be drilled with holes to fit the spindles, holes in each foot to receive the holding studs, and small oil holes in each bearing, then filed smooth, and polished neatly. The projecting boss of one of these bearings must be turned to form a pivot for the brush rocker, which will fit on this like a loose sleeve, and the insides of the spider legs and bodies should also be turned smooth.

*The Brush Rocker.*—The casting for this is shown at Fig. 6. The hole in the centre must be turned to fit the pivot on the boss of the bearing above-mentioned; then there must be a small hole drilled and tapped in the edge of the rocker to receive a small brass set screw for fixing the rocker on the pivot in any required position. The small brass castings, shown at Fig. 7, must then be turned and filed to the form shown at Fig. 10, to form brush-holders, and these are held in holes drilled through the ends of the rocker. The part from A to B, Fig. 10, is first turned down to $\frac{1}{4}$ in., and a thread chased on it to receive a brass nut. The hole in the end of the rocker is drilled $\frac{1}{16}$ in. larger, and this is to be bushed with vulcanite or a bit of asbestos board, with a collar of the same on each side, to insulate the brush-holder from the rocker. A fairly good bush can be made from a small washer of rubber cut off from the end of a piece of rubber tube, and two collars of thin cloth to come between the shoulder of the brush-holder and the rocker on one side, and the nut and the rocker on the other; but these are liable to be destroyed by oil. The plain end to the right of the chased thread must be pierced transversely with a $\frac{1}{16}$ in. hole to receive the conducting wire, and this hole is met with another, drilled in from the end, and tapped to receive the thread of a binding screw furnished with a milled head, as shown at Fig. 11. The other end of the brush-holder is turned down smooth, a $\frac{1}{32}$ in. slot is to be cut up to the shoulder, one side of the holder filed flat, and a $\frac{1}{16}$ in. hole drilled through both, the lower half of the hole being tapped to receive the screwed part of a brass set screw.

*The Brushes* are strips of phosphor bronze foil, 2 in. by $\frac{7}{16}$ in., cut from the roll sent with the castings to the form shown at Fig. 12. Six of these strips are placed together to form a pad. The ends at one end are soldered together, and a slot, $\frac{1}{2}$ in. by $\frac{1}{8}$ in., cut through the whole in the middle to receive the adjusting and tightening stud. A set of these are, of course, at each end of the rocker.

*The Commutator.*—As on this form of armature there is only one coil, the two ends of which are connected to two parts of the commutator, a two-part commutator, made out of a ferrule of brass split into two equal parts, will be required. The piece of brass tube sent with the castings has an internal diameter of $\frac{11}{16}$ in. This is fitted on a boxwood boss $\frac{1}{2}$ in. in width, which is then bored with a hole to exactly fit the spindle at that end of the armature with the wire holes drilled in the end. The ferrule is now to be scribed into two equal parts, and on each side of the dividing lines scribe two more lines, so as to have the three lines on each side $\frac{1}{4}$ in. apart. Through the centre of the two side lines drill a small hole into the boxwood to receive two short brass screws. Countersink the mouths of these holes, and screw in the screws tightly. Do the same on the other side of the commutator. This done, cut the ferrule into two equal parts with an oblique cut as shown at Fig. 13. This is best done with a hack-saw, so as to make a clean cut through the brass into the boxwood beneath. The boss, with its split ferrule, may now be pressed on the spindle, and trued up in the lathe. In pressing on the ferrule, let the inner ends of the oblique cuts coincide with the wire holes in the armature ends.

*Winding the Armature.*—This is a simple matter. Measure off 60 ft. of No. 20 double cotton-covered copper wire, roll into a hank, and soak for a quarter of an hour in melted paraffin wax, then hang up to drain and cool. When cool, take the armature in the left hand, and the wire in the right. Place

the commencing end of the coil (with 2 in. left free) at the left side of the channel, and hold it down with the left thumb whilst the wire is wound closely around the web of the armature in regular coils, side by side, to the right side of the channel, then back again with the same care and regularity, until all the wire has been wound on in regular and even layers. Then twist the two ends together to keep them from springing apart and the coil from unwinding. Test each layer for insulation as they are wound on, and test the whole coil again when complete.

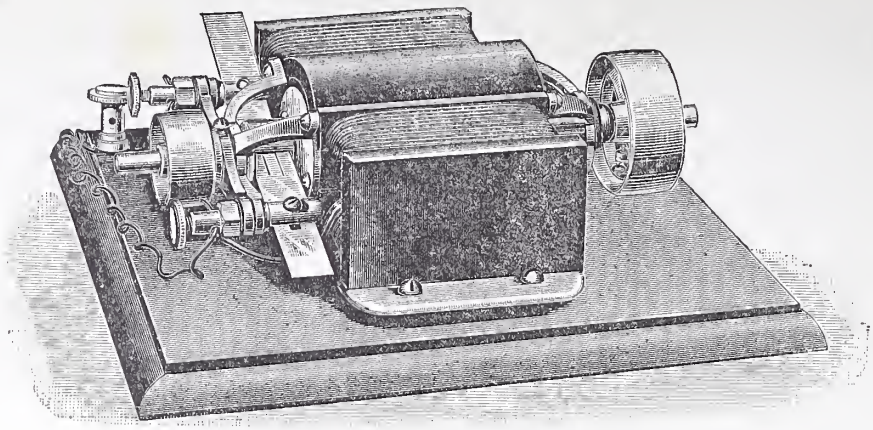

Fig. 1.—Model Electro-Motor: Siemens Bridge Type, complete.

The end-pieces may now be put on, then the ends of the armature coil may be brought out through the bushed holes in the ends and connected (by soldering each end) to each part of the commutator. The ends should be soldered to the inner edges of the commutator pieces, along which they may lie to the length of ½ in. The coil may now be given a coat of sealing-wax varnish to set the wires; then set aside to dry,

*Winding the Field Magnets.*—The field magnets of this little motor must be so wound as to cause the arch above the armature to assume a magnetism of opposite polarity to that of the arch below the armature. It matters but very little whether we have a north pole at the top and a south pole at the bottom, or a south pole at the top and a north pole at the bottom, providing both are not north poles and both south poles. This desired end is accomplished by winding the core on one side of the arch in one direction, and the core on the other side of the arch in the opposite direction. Thus, if we wind the left-hand core of the top magnet from left to right overhanded, we must wind the opposite or right-hand core in the opposite direction, namely, from left to right underhanded. This will ensure a north polarity to the upper arch. In commencing to wind the lower cores from the left-hand side, we must wind the left-hand core overhanded and the right-hand core underhanded. This will ensure a south polarity to the lower arch, as shown in the diagram (Fig. 9), if the current is sent through the wires as shown by the direction of the arrows. Wind each core regularly with three layers of No. 20 double cotton-covered copper wire, and test each layer for insulation. When the last turn of wire on each core has been reached, cut off the wire so as to leave 6 in. over and above that needed to make the turn; pass this in under the turn of wire so as to form a kind of half-hitch, and draw this tight to prevent the wire from unwinding; then give the whole a dressing of sealing-wax varnish to secure each coil in their places, and to give the coils a finished appearance.

When the machine is being put together, these coils must be connected together as here described, and shown at Fig. 9. The finish end of the first coil at A must be bared of the cotton covering and cleaned with emery cloth; so also must the commencing end of the second coil on the next core at D. Dip both cleaned ends in some soldering fluid, tin them with a hot soldering bit, twist the tinned ends together with a pair of pliers, then give them a final touch with the soldering bit to solder them together. Each end must be thus treated and connected, namely, A to B, C to D, and E to F. The two ends, C D, may pass down holes made in the motor base, and be connected beneath the base. The two free ends above the upper arch will then go, one to one of the brushes, and one to one of the terminal binding screws on the base, if the coils are to be connected in series with the armature; or both of these wires will be connected to the brushes if the coils are to be connected in parallel with the coil on the armature.

*Fitting the Parts Together.*—The field magnets may first be fitted together, the ends of the coils soldered and tucked in out of sight, the screws holding the two cores, inserted and screwed tight, and the brass

Fig. 2.—Field Magnet Casting of Electro-Motor. Fig. 3.—Armature Casting. Fig. 4.—Gun-Metal Casting for Armature Ends. Fig. 5.—Gun-Metal Foot for Electro-Motor. Fig. 6.—Rocker for Brush-Holders. Fig. 7.—Casting for Brush-Holder. Fig. 8.—Casting for Screw. Fig. 9.—Sectional Diagram of Electro-Motor, showing how it is fitted and wound. Fig. 10.—Brush-Holder complete. Fig. 11.—Brass Screw with Milled Head. Fig. 12.—Brush. Fig. 13.—Commutator.

feet screwed on. We should next fit on the already turned and polished spider bearing to the opposite end from that of the commutator; then put in the armature, slip the other bearing on its spindle, and screw this bearing in its place. Now turn the armature around by hand, and see that it runs true in the tunnel, not touching it anywhere, but parallel with it on all sides. The back pulley should now be fitted on the spindle, and tightened on it by means of a small set screw passing through the boss on the outside. The rocker may next be fitted on, and secured to the outside of the bearing by a small set screw. One of the brushes will have its free end bearing on top of the commutator, and the other brush will press lightly against the under side of the commutator. Their relative positions will be determined by the direction of rotation of the armature, the commutator running off from the brushes, but not against them to ruffle them up. The right angle to set these must be found by experiment. The rocker can be easily moved until the best effect has been obtained, then fixed in this position by the set screw. The smaller pulley is now slipped on the spindle, the armature brought forward until it runs freely in the position where it ought to work, then the pulley must be tightened on the spindle to prevent undue end shake of the spindle in its bearings. A little end play or shake is always admissible, but side shake, due to loose fitting in the bearings, must never be allowed in electro-motors. The motor may now be mounted on a wood base made of oak, teak, or mahogany, and furnished with brass terminals to the wire coils, as shown at Fig. 1. The little motor sent me by Mr. Atkinson is mounted on a polished oak base 10 in. by 8 in., furnished with carved oak legs at the corners, and holding-down clamps of polished brass at the sides. Thus fitted and finished, the price complete is 42s.

As it is advisable to test the insulation of the wire whilst winding it on the cores and armature, we must be provided with a galvanometer of some sort, and a cell of some battery. Almost any battery will serve the purpose. Connect one terminal of the battery to the commencing end of the coil being wound on. Connect the other terminal of the battery to one stud of the galvanometer. To the other stud of the galvanometer connect about a foot of copper wire, and use the bared end of this to touch and scrape the iron on which the coil is being wound. If the needle of the galvanometer is deflected—that is, moves from its position of rest—then the bare wire is touching the iron, and the bare place must be found by unwinding the coil. Cover the fault with a few strands of soft cotton soaked in melted paraffin, or with a bit of silk ribbon, then proceed again. If the galvanometer needle does not move, proceed with the winding, and test again further on. A small galvanometer, suitable for this purpose, is sold by Mr. Atkinson for 3s.

## HOW TO MAKE A PUZZLE MONEY-BOX.

BY FRED CROCKER.

Setting out the Pattern—Cutting the Ends—Putting Together—Puzzle Picture Frames.

The subject of the present paper suggested itself to the writer on being asked to contribute some small article for sale at a bazaar, and, judging by the results, I should think that if any reader of Work should find the same task put before him, he could not make a more satisfactory and desirable article. The following notes will describe the method of manufacture:—

Procure a strip of wood—Honduras mahogany will do very well for the purpose—2 ft. 6 in. long × 2 in. wide × ¼ in. thick: this must be dry, or the box will soon fall to pieces. Cross-cut it into six 5 in. lengths. Take one piece for a pattern, and set it out exactly as shown in Fig. 1. Groove it at A and B, making the grooves ⅛ in. deep and ¼ in. wide. Cut the ends as in Fig. 1, or as shown in the other designs, Figs. 4 and 5; then make the other five pieces just the same as No. 1, with the addition that one of them will require a slot for putting in the

money. This may be mortised with a fine bradawl and cleaned out with a key-hole saw and piece of glass-paper. The slot should be 1¼ in. long, so that it will just pass a penny, and our box is ready for putting together. The sketches will explain the method of doing this. For clearness, I have numbered each piece. Put No. 1 (see Fig. 2) on the table; add Nos. 2 and 3; then 4 and 5, as shown in Fig. 3; finally put No. 6 in position. Force it down with the thumbs. It will be found that Nos. 2 and 3 will spring sufficiently to allow No. 6 being forced into its place. It will then key all the others; but if the wood is brittle and there is danger of splitting, it may be eased at the side, as shown in Fig. 4.

Figs. 4 and 5 give suggestions for cutting the ends if the reader has a fret-saw. In Fig. 5 it is supposed that the box is to be given to a child, the ends being cut with his or her monogram.

Of course it is not necessary to adhere blindly to the dimensions given. The pieces may be made 2½ in. wide, and the grooves made further apart accordingly, bearing in mind that in all cases the distance from out to out of grooves must equal the width added to the depth of both grooves. Again, the box may be made with the ends plain or simply rounded; and if no better material is handy, the cedar of a cigar-box may be utilised. It is scarcely necessary for me to add that each piece should be cleaned off with glass-paper before putting together.

Puzzle picture frames are put together in much the same manner, each corner being a miniature copy of the money-box.

## OUR GUIDE TO GOOD THINGS.

*** *Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of* Work *for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of* Work *without charge, the notices given partake in no way of the nature of advertisements.*

### 6.—The Indiarubber "Grip" Handle Cover.

Messrs. P. B. Cow & Co., 46 and 47, Cheapside, E.C., send a specimen of their new Indiarubber "Grip" Handle Cover (Caffarey's Patent) for enabling those who use them to obtain a firmer grasp and hold than can be obtained by the hand alone without any intervening medium on the handles of tennis rackets, cricket bats, sculls, handles of cycles, and clubs and sticks for golf, lacrosse, polo, and hockey. The cover is in the form of a bandage with a rough or embossed surface externally, and a smooth surface internally, fitted with a stud and eye at one end, the stud being reversible, so that the cover may be put on so as to bring either surface, as may be preferred, in contact with the hand. Being, as it has been said, in the form of a bandage—the sample before me, intended for a cricket bat, being 36 in. long and 1¾ in. wide—it is wrapped round the handle, starting from the end without a stud, each fold overlapping the preceding one, the operation being completed at the other end by slipping the eye over the stud. It may be said that this new handle cover is entirely free from the objections that attach to the old tubular form of cover, the chief of these being the difficulty of pulling the latter on to the handle owing to its being, of necessity, made somewhat smaller than the handle it is intended to fit—a difficulty "frequently resulting," as the manufacturers point out, "in pinched fingers, loss of temper, and splitting the cover." As a matter of course, that which is difficult to put on is also difficult to remove; and conversely, that which is easily applied can be taken off with equal facility. This gives the new cover an additional advantage over the old one, and enables any cricketer who has occasion to change his bat to transfer the handle cover from one to the other in a very short space of time. The manufacturers claim that the new cover is "most effectual, very durable, and inexpensive." I have no doubt whatever as to its utility and durability; and with regard to its cheapness, it will be sufficient to say that covers for all articles cost only 1s. each, the only exceptions being those for cycles, which cost 1s. 6d. per pair, and scull handles, which are sold at 2s. per pair. They further state that a tennis racket handle cover "may be used for a cricket bat, and *vice versâ*, the only difference being in the length. In the case of oars and sculls, the rower can produce his cover, and apply it to any scull he may happen to use. With golf this is a great advantage, the clubs being frequently changed. The 'Grip' rolls up into the smallest possible compass when not in use, so can be readily carried in the pocket. For cycle handles, which vary so much in size and shape, the same handle cover will fit equally well all sizes and shapes, an advantage hitherto unattainable in any other handle cover. When the old form of cricket and tennis bat handle cover works loose, it becomes practically useless. The 'Grip' never works loose." I do not see, myself, why the new covers should not be turned to good account for augmenting the grip on the handles of pickaxes, hatchets, adzes, heavy hammers, and similar tools. It would obviate, for amateurs, at all events, that salivatory process which is sometimes necessary to assist in attaining a firmer grasp on the handle of a heavy tool that has become polished by the friction resulting from constant use.

### 7.—Proctor's "Defiance" Writing Inks.

Messrs. John M. Proctor & Co., St. Ann's Ink Works, Nottingham, have submitted samples of the various inks and writing fluids manufactured and supplied by them, and also some dry inks or inks in the form of powder, which can be rendered fit for use in a very short space of time by dissolving the powder in cold water, and shaking it until the powder is dissolved. Having made trial of these inks, I can say with pleasure that they are excellent, and satisfy in every way the requirements that men and women generally are apt to insist on when selecting an ink for their personal use. The most noticeable points with regard to these inks are—firstly, their perfect fluidity, which secures perfect freedom in writing, and enables the writer to skim over the surface of the paper, *currente calamo*, as the phrase goes, and to get a marvellous number of words on the paper with a single dip of the pen. For my own part, I am accustomed to write very fast and very small; and to do this with clearness and legibility one requires a light touch, a fine pen, and ink free from the clogginess, if I may use the expression, that seems inseparable from many kinds of ink, which are so muddy in themselves and contain so much sediment as to render them well-nigh intolerable. The special ink about which I am now speaking is, I take it, the cheapest of Messrs. Proctor & Co.'s inks, being an ink prepared for the use of schools, and supplied in nine-gallon casks at 1s. per gallon. They supply inks that are higher in price, but, as far as I am concerned, I am perfectly satisfied with this inexpensive ink without going to a higher price. Secondly, as the ink is so perfect a fluid, it neither clogs the pen nor causes the formation of an incrustation about it, which soon corrodes it and renders it useless. To go at length into the various inks supplied by Messrs. Proctor & Co. is not possible, owing to their number and variety, but what may be said of one kind may be said of all. The varieties include blue-black fluids for writing and copying, black inks for writing and copying, violet-black ink, inks of special scarlet, bright red—an excellent ink — machine-ruling inks, fancy coloured inks in mauve, magenta, purple, green, blue, and violet; endorsing inks for indiarubber stamps; and multiple writing ink of a violet tint for graphs. The dry inks for mixing with water will be found useful by travellers and emigrants. Prices of the various inks manufactured by Messrs. John Proctor & Co. will be supplied on application. I noticed some little time ago, in Work, a sample board covered with Proctor's "Defiance" Slate Composition; and may now take this opportunity to call attention to Proctor's "Defiance" Slate Paper, faced with the composition for diagrams, drawing examples, etc. The composition does not wash off, and it is said that the paper is so durable that it may be used any number of times. It is sold in two sizes—3 ft. by 2 ft., at 6d. net, and 4 ft. by 3 ft., at 1s. net. The slate paper will be found extremely useful, not only in schools where something supplementary to the blackboard is required, but also in lecture-rooms and class-rooms where the lecturer requires a medium that may be speedily available for the diagrammatic illustration of his remarks.

### 8.—New Patent Non-Conducting Covering for Steam Pipes.

The Cortex Calorifuge Company, Limited, 3, Fenwick Street (offices), and 19, Hanover Street (works), Liverpool, send me a letter and pamphlet relative to a patent cork covering for steam pipes that they are now manufacturing and supplying, which is known as the Cortex or Cork Covering. The Company's manager, Mr. H. E. L. Grundy, writes:—"We are manufacturing a new kind of non-conductor for the covering of curved or straight steam pipes, to prevent radiation and reduce the consumption of coal, and carry steam a much longer distance, either inside or outside of buildings. The covering is made of pure solid cork, and can be bent to suit any diameter or shape of pipe. The cork is cut into long strips; the ends of each are bevelled, and then joined and coiled into strips of eleven yards. A covering of linen at the back of the cork enables it to be bent and wrapped around steam pipes with the greatest ease. It is a natural non-conductor, and in its wild state has to resist heat, frost, and water, so that it is specially adapted for non-conducting purposes, being so durable and light." Of course, we all know the nature of cork, and are acquainted with many of its adaptations for mercantile purposes; and being well aware of its qualities and characteristics, there is no difficulty in accepting all that Mr. Grundy says with reference to it. Moreover, it is highly commended by various engineers and naval architects who have tested it on the steam pipes of large steamers. It is made to suit various sizes of pipes in strips from ¼ in. to ⅝ in. thick and 1½ in. wide, and is sold by the square foot, and according to thickness, at 1s. 6d., 1s. 7d., 1s. 8d., and 1s. 9d. per square foot. The coils in which the cork covering is supplied are between 11 yds. and 12 yds. long. To fit it on to the pipe, the coil is first unrolled on to the pipe loose, and then lies slack about the pipe. One end of the cork is then secured with string or wire, and the slack is tightened up by wrapping it closely round the pipe. The ends of the cork strips being bevelled and covered with a solution, all that is necessary in order to join them is to press the two ends together and overlap the spare linen backing of the cork which is left at each end for the purpose. When this is done, the cork coil should be overlaid in the contrary direction with a linen tape, specially prepared with a solution which is applied to the inside surface of the linen. This linen, with the dressed surface innermost and touching the cork, or rather, the linen with which the cork is backed, is wrapped tightly and closely round the cork covering, and the operation is completed. In the case of curved pipes, a little must be cut from the edge of the cork on the inside, or the gaps on the outside must be filled in with small pieces of cork covered with linen. A very neat appearance is imparted to the covering by applying a coat of white lead or zinc to the linen envelope. This tends to preserve the linen, which, it should be said, is supplied at the rate of 3d. per square foot. The Editor.

## SHOP:

A Corner for Those who Want to Talk It.

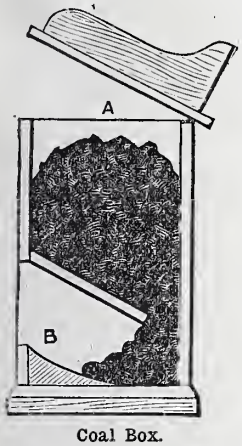
*** *In consequence of the great pressure upon the "Shop" columns of* WORK, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* WORK *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### I.—Letters from Correspondents.

**Fretwork.**—F. C. (*Leytonstone*) writes:—"Some time ago, in a letter to WORK, I suggested an easy method of taking a number of copies of a fretwork design—viz., clamping two pieces of wood together with several sheets of paper between them; then cutting out in the usual manner. This gives you two copies of the design in wood, and as many in paper as you please. Now suppose if, instead of using paper, you place a sheet of thin metal, such as is used for cutting stencil plates, between the two pieces of wood, then cut out, it will make very little difference in the working of the saw, and you will have a stencil plate from which any number of designs may be reproduced."

**Coal Box.**—H. B. (*Haydon Bridge*) writes:—"I would respectfully suggest to W. H. P. (*Hornsey*) an improvement on his coal box (see page 731, Vol. II.). If he will put the coals in at top (A), putting the top on hinges, he will get more room for coals, and his top will be as available for table purposes as ever. I would also have the floor of the box curved downwards, as at B, so that when the coals were thrown in at A, the box being empty, none would find their way out at the bottom. His idea is a good one. As I use stoves with coke, broken to sizes, according to strength of the wind, I intend making one."



Coal Box.

### II.—Questions Answered by Editor and Staff.

**Varnish.**—D. B. (*Durham*).—As has been frequently stated in the "Shop" columns, varnishing is not a good way to finish furniture of any but the commonest and roughest kind. The best "varnish" is French polish. This you can make by dissolving shellac (6 oz.) in methylated spirit (1 pint). It is not suitable for brush work. Ordinary varnish making cannot be well practised by an amateur. You will find it better and more economical to buy what you want ready made, as you can easily do in your own neighbourhood.—D. A.

**Incubator.**—T. M. (*Deptford*).—The T-shaped tube and regulator work as sketch, Fig. 1, the parts being lettered as in the original drawing (Fig. 1, page 589, Vol. II.) The difference is, as you will see, that the damper lever must be altered as shown, when the float will open damper instead of closing it, as you imagine. You will economise heat by turning the end of the flue pipe, D, up through the tank, as I have shown, instead of outside, as shown by Mr. Walker. The regulator I recommend is a glass tube filled with mercury and ether (see Figs. 2 and 3). If you can, run the lifting rod, E, up through centre of machine. Fig. 2 is best; but if you place regulator at back of egg drawer, Fig. 3 will be preferable, as the bent arm will project over the eggs. It consists of a glass tube of about ⅜ in. calibre, bent as shown, and the end A sealed over. When obtained, fill the tube sufficiently with mercury, C (shaded dark), then add a small quantity of dilute ether, and agitate the tube until the fluid assumes the position B (shaded light), with a small air bubble at the sealed end A. This operation is difficult to describe, but is easily done when you know how. If you place your forefinger over the open end of tube, and turn it upside down and about a few times, the ether, being of the lightest *s.g.*, will assume the uppermost position, and by a few dexterous manipulations can be confined in the sealed end. This having been accomplished, fit a small float, D, to slide easily in tube. This may be made of a piece of ivory, nicely turned to fit; or a small cork can be fitted. Into this float fit a stiff straw or a piece of fine hard wire, E, to act as the lifting rod actuating the damper; and after testing, cut same to required length. A small braeket, F, made of any sheet metal, with a hole drilled in it to fit rod, will keep it straight and prevent float jambing in the tube. The action is thus:—Ether boils at a very low temperature and gives off a vapour. Being imprisoned, it cannot escape, and therefore forces the mercury round into the long limb. This, in turn, raises the float, and this, with its rod, tilts the damper lever, and allows the heat to pass straight away instead of going through the tank. This will be found a most sensitive regulator, and is the best I know of. I think I have made all clear; if not, write again.

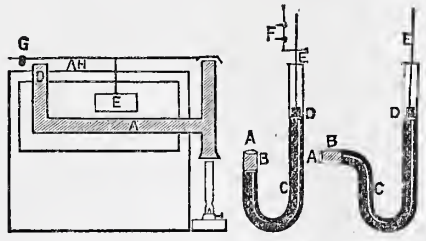


Fig. 1. Fig 2 Fig. 3.

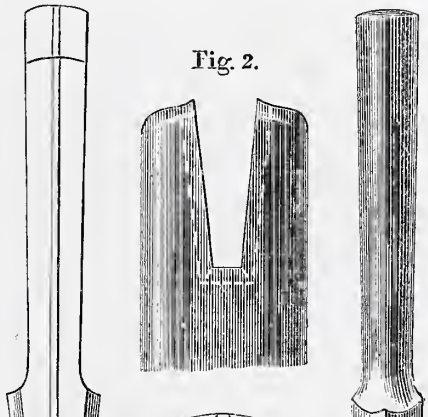
Incubator Parts.

I cannot suggest any improvement in the damping arrangement described by Mr. Walker *for a hot-water machine*, my remarks as to improved damping being confined to machines of the *hot air* class. Give eggs a sprinkling every day during the latter half of period of incubation with warm water, and during the last day or two a few seconds' soaking in water at about 100° Fahr. will minimise the chance of a goodly number being found "dead in shell."—Leghorn.

**Cricket Bat.**—No Name.—You do not state whether you wish to make a new spliced bat or want to repair a broken bat. In the latter case, how can I advise you without a tracing of the fracture? In the former, I may tell you that there is considerable art in splicing a bat to ensure a springiness when a blow is struck, so that such elasticity may act as a secondary force. Celebrated makers use pieces of whalebone half-way up the handle, and one-third down the bat to achieve this result. Some make the handle of lancewood; some of willow, which seems the favourite wood for the bat itself. If I were making a bat, I should have the handle turned of hickory, and left 6 in. longer than I wanted for handle, and then plane it to a wedge shape, as shown in the illustration, marking the bat at the same angle, but cutting it smaller, so that a V-joint is made as shown in diagram in section. This can only be done with a chisel, carefully getting the four surfaces, A, B, C, D, to fit accurately; the end of the handle should be also chamfered off, fore and aft, and the bat itself recessed inwards to receive this V-shaped joint, taking care to make it $\frac{1}{16}$ of an inch too short when in place before gluing, and driving it home when you are satisfied with the fit. If you like to go to the trouble of gluing up the handle first with a strip ⅛ in. thick of whalebone between two pieces of hickory before it is turned, you may attain more "springiness." The after-process of stringing the handle will ensure that the joints will not re-open above the splice, whilst the wedging below will compel that portion in the bat to keep close. To add to the springiness, taper the round part towards the lower part of the handle, so that being thinner the spring may date from the junction of bat and handle, and not below, or the strain may shake the splice. Then wind on the string (good fine whipcord well waxed with cobbler's wax is best), and soak the bat with raw linseed-oil, or better still, oil it with raw oil every two days for a month, feeding the butt end with all it will absorb, which will prevent the blows on the bat from the hard ball from even marking it; by well rubbing it with oil thus day by day a very high polish will result. You say you do not like pins, but I strongly recommend, after the handle is housed home and the glue is set, boring with a $\frac{3}{16}$ in. Morse bit two holes right through bat and handle (bored through from the side, of course), and then *rosewood* dowels, $\frac{3}{16}$ in. full, driven right through with thin glue to obviate any tendency of the handle to spring *below* its junction with the bat, which I hold to be fatal.—J. W. H.



Cricket Bat Splices.

**Binding Work.**—W. K. S. (*Liverpool*).—You made a big mistake in trying to wash off the glue from the back of sections of the monthly part. The proper method is to scrape them carefully with a knife, which must be used with caution and intelligence. It is possible to make a greater mess with the knife than with the water, but it is possible to take all the glue away if care is taken. There is a certain method of using the knife so as not to cut or tear, which I cannot express in writing, but which I could easily put you up to in five minutes, but you must try and find it out for yourself. Use the knife, and be careful, and you will succeed, I hope.—G. C.

**American Clock.**—D. H. (*North Shields*).—I cannot help you to design a ease, but if you bring the weights down as you suggest, you must allow the pendulum to pass to and fro in *front* of them, and let there be an inch at least between; and bear also in mind that by having a double line, as you suggest, instead of single as before, that your weights must each be double the present ones—that is to say, that as they weigh about 3½ lbs. each now, the ones you make must be about 7 lbs., because each line takes half; therefore there will be 3½ lbs. pulling the clock, and the other 3½ lbs. pulling at the knot where tied up. The drop, of course, must be the same as before.—A. B. C.

**Polishing and Burnishing.**—G. N. (*No Address*).—It depends on the shape of the articles. Sometimes a leather buff charged with fine emery or crocus is used; sometimes a burnisher, which may be a half-round file ground and polished quite smooth. No special apparatus for turning small wood handle, only dexterity acquired by practice.—J.

**Gold Leaf.**—Trefaldryn.—Your note reads as if you had seen a gilder at work (who had already sized the pattern on to a bracket or brackets) take a leaf of transferred gold, and press it over the place where the pattern was already sized in, and being nicely done, when he removed the transfer-paper the design or pattern was left quite clean on the bracket, the transfer-paper retaining all the superfluous gold not taken up by the design. You can obtain every description of tiles of Craven Dunnill and Co., Jackfield Works, Salop. Write for illustrated price lists, stating quantity required.—E. D.

**Gas Engine.**—L. T. (*Harlesden*).—There is not space in "Shop" to give full instructions for making a gas engine, and partial ones would be useless. The standard work on gas engines is that of Mr. Dugald Clerk, C.E. In reply to your second question, you may certainly put a copper fire-box and copper tubes in an iron boiler; it is a common practice in locomotive engineering.—F. C.

**Proportions of Engine.**—Faithful Reader.—If you will state the parts of the engine for which you require formula, the description of engine, and the work for which it is required, I will send you full particulars.—F. C.

**Electric Lighting.**—Turbine.—A turbine is the best motor to use. You should send *full particulars* to some firm of electrical engineers—such as Messrs. Cooper & Paterson, Victoria Street, London, from whom you may get complete information, and an estimate of the cost of an installation, such as the power at your disposal will serve.—F. C.

**Book on Electric Bell-Hanging.**—James.—"Practical Electric Bell Fitting," by F. C. Allsop. Price 3s. 6d., post free, from Allsop & Co., 165, Queen Victoria Street, London, E.C.—G. E. B.

**Wood Carving.**—J. M. (*Newport Pagnell*).—It is impossible to give you any very definite advice. You had better find out the best shop where carving is done in the nearest large town, and see if you can arrange with the master to take you on as an "improver." I should think there were good places within reach of you; and if so, you would do better there than by coming to London, unless you can afford to come up for a day or so, and go the round of the shops. Try Rogers, of Maddox Street, London.—M. E. R.

**Making Blacking and Ink.**—A Labourer.—As an ordinary paste blacking for shoes, the following is recommended by Dr. Ure:—Ivory black 2 lb., treacle 1 lb., olive oil 4 oz., well mixed together. Add 4 oz. sulphuric acid; and when this has ceased to act on the ivory black, add also ¾ oz. gum Arabic in powder, 5 oz. vinegar, and ½ oz. sulphate of iron dissolved in 5 oz. water. All must then be well mixed together. A cheaper paste than the above may be made of ivory black 1¼ lb., treacle 1 lb., olive oil (or some cheaper oil may be substituted—rape oil or fish oil will do) 2 oz.; well mix into paste with strong vinegar. A liquid blacking may thus be made:—Ivory black 3 oz., treacle 2 oz., sweet oil ½ oz. On these pour ½ oz. sulphuric acid. Afterwards well mix these up with ¼ pint vinegar and ¾ pint water. Or, here

is another cheap and favourite liquid blacking :—Ivory black 2 lb., treacle 1 lb., sweet oil 4 oz., sulphuric acid 4 oz.; to be mixed to the proper thickness with beer bottoms. It may be observed that the use of sulphuric acid (oil of vitriol) in blackings is neither good for the leather or the sewing of shoes. A harness blacking which needs no labour in polishing is thus made:—Gelatine 4 oz., gum Arabic 3 oz., dissolved in ¾ pint of hot water. Strain and place in pan over fire; then add 6 oz. treacle, and afterwards sprinkle in 6 oz. powdered lamp-black. Boil till the mixture thickens, stirring all the time. As regards our ordinary writing inks, they are made of iron (in the form of copperas or sulphate of iron) and of gallic acid (in the shape of nut-galls) boiled in water with a little gum to give body and adhesion. If A LABOURER will get No. 31 (Vol. I., page 493), he will there find receipts for making inks of various colours, with other information on the subject; but we may here give him the rule by which the ink used in the Court of Exchequer, long regarded as of special excellence, was made, and which was divulged before a Committee of the House of Commons:—Galls 4 lb., gum 1 lb., copperas 14 oz., and rain-water 4½ gallons. —S. W.

**Banjo Matters.**—SUSSEX BANJOIST.—The number of brackets you mention (twelve) are not sufficient for a 12 in. hoop. You ought to have at least twenty-four, and not more than thirty. If you use more than thirty brackets you only add to the weight of the banjo, without having any additional advantage. I am not surprised at your banjo not being a success, considering that you have used only twelve instead of twenty-four brackets. You must have enough to pull the vellum tight, for however good a rim you may have, if your vellum is not very tight it will not sound up to the mark. When your vellum is pulled down and fairly stretched, it should feel almost like a piece of board on applying pressure of thumb or finger against it. To get it like that, you must put it on with the band standing well up, and then pull down carefully a little at a time until the top of the band is level with edge of hoop; but as some vellums stretch more than others, the band is often pulled below the level of the edge of rim (or hoop) before the vellum is properly tight. Pulling down the vellum requires care and judgment, not to be taught by written instructions. There is nothing like breaking a few vellums in the pulling down for teaching what ought and what ought not to be done. Never wet a vellum after it is put on the banjo; if you do, and you pull the vellum tighter, you are almost sure of breaking it. I should as soon think of filling the inside of a violin with water as to wet a vellum after it has been put on. The metal to use for hoop is German silver edges spun over steel wires, and lined with oak, maple, or sycamore. It is also important that the band is strong, say about ⅜ in. deep, ⅛ in. or $\frac{1}{16}$ in. thick, and having a recess turned in it to keep the brackets from touching and cutting the vellum; or notches could be filed in to receive the heads of the pulling-down wires, and so keep them clear of the vellum. The longer the handle, and the larger the hoop, the lower and deeper tone you will get, and also more powerful. A banjo with a 20 in. handle and a 12 in. or 13 in. hoop cannot be tuned up to concert pitch, but must be tuned a tone lower; the strings of such a long banjo would not stand if pulled up to pitch. The best and most convenient size will be one with 18 in. handle and 12 in. hoop, or 19 in. handle and 11 in. hoop. A banjo made to this size, and properly strung, can be tuned up to concert pitch to play with piano or other instruments. The higher your bridge, the louder the tone; if you have your bridge too high, you will not feel so comfortable when playing as you would with a lower one. It will give you a better idea which suits you the best if you try two or three bridges of different heights. In starting the vellum when putting on, the pulling-down wires ought to be put on opposite one another, as shown in your sketch, and when you have got them all on, commence to pull down at one, and follow on right round the hoop. After the vellum is on and dry, you must not on any account give one but a turn and then go to the one opposite, but must go to the next one, and so on round the hoop. If you carry out my instructions you will get the proper banjo tone. The great secrets are experience, good workmanship, and the best materials.—J. G. W.

**Hammock Chair.**—H. B. (*Hammersmith*).—You are not quite clear as to what a rivet is, and what a bolt is. What you want are some ¼ in. bolts and nuts 2½ in. long—that is to say, if you are working in 1 in. stuff—as it will be double thickness; but go to any ironmonger, and you will get them. Rivets are entirely different things, and used for another purpose altogether. I can quite see you had a trouble to get what you wanted if you asked for rivets.—J. B.

**Chords for Organette.**—R. B. (*Pallas Green*). —This question much resembles one which has already appeared in "Shop," and R. B. would do well to look out for it. I should like to answer R. B. as follows:—The chords possible on an organette depend upon the number and relation of the reeds —in all probability the organette will only play in two or three keys, and the question would be easily answered if this information had been supplied. If R. B. knows anything of music or the tonic sol-fa notation, it would help him, but in ignorance of this, I may say that the keynote chord—that is, the first, third, fifth, and eighth of the scale—is the most useful and important chord. It can be used in any position or inversion, but not at the first and last chord; there, inversions are not to be used. Next in importance is the similar chord founded on the fifth as a root, and harmonising the fifth, seventh, and second of the scale. This chord may also be used in an incomplete form, inverted or rearranged as to the upper intervals. Of still less importance is the similar chord founded on the fourth, supplying harmonies for the fourth, sixth, and eighth. This chord may also be inverted or the upper intervals transposed. Thirds are to be used freely: every chord should have one in its composition, but not always between the same two parts, or minor effects would be produced where least desired. A succession of perfect fifths is not tolerated; even two in succession are objectionable, and fifths without thirds are not pleasant. Octaves are pleasant, but not a continuation of them between the same parts. It is, however, allowable to play a bass part with octaves added below, and a treble part with octaves added above. Here also we need to know the compass of R. B.'s organette. In addition to these three chords, which are subject to many changes of position, giving variety, there are many more artificial chords, sounds for which are not probably provided on R. B.'s instrument.—B. A. B.

**Bar Magnets.**—W. H. O. P. (*Hackney*).—In London! and yet you cannot get a pair of round bar magnets. Why, I wonder at you! Take a walk down the Strand some Saturday afternoon and look in the opticians' windows, and if you do not get a pair, I'll eat my hat. But if you cannot get them round, you will certainly get them flat. Take the nearest you can get to the size you want and make the holes in the case to fit them. Flat magnets will do just as well as round ones for your purpose. It is not necessary when buying these to state the purpose you have in view. Ask for round bar magnets at any electrician's or optician's, and I am sure you will get them.—W. D.

**Blocking, Burnishing, Relief, etc.**—JOINT.—(1) A good dry powder for blocking Dutch metal on cards, etc., may be had from Messrs. Berry and Roberts, St. Bride's Street, London, E.C. You might try powdered resin or gum sandarach. Tie in a small muslin bag, and dust over the card. Lift the metal in the stamp, as you cannot "lay on" on the top of the powder. (2) Very likely the want of experience is the cause of your colours looking smeary and spreading, if, as you say, you use the best colours and varnish. But what are they? Use dry colours and white crystal varnish, and grind them well on the slab. Put it on the die with a hard brush, and wipe on hard paper. Do not use turps. (3) I gather that you do want experience. The gold burnishing is done in the way you have been trying to do it. But what in the world do you put the piece of thin copper upon your die for? Allow your work to become thoroughly dry, and re-stamp again and again. (4) Do not be afraid of wearying me. There are different methods of doing relief stamping in two or more colours. One of them is by getting two or more dies, which, put together, make one complete—that is, supposing you want to have J B interlaced, each having a different colour, you get one die with J on it, and one with B on it. You put in B first, and stamp the paper with it, gilding it if you like; then you put in J, with a different colour, and stamp upon the top of B. Of course, the dies are cut specially for this class of work; and when finished, it looks as if it had been struck with one impression. Another method is by painting in the different parts of the monogram on the die, and wiping and stamping in the usual manner. (5) See question 2 for answer to this.—G. C.

**Water-Tube Boiler.**—GENERATOR.—The tube you propose is very old, and its use has been several times patented in different forms, notably in "Field's" boiler. It would not answer as you have shown it, as there is no provision for circulation. I do not know that the matter to which you refer is patented; that can only be ascertained by a search at the Patent Office, or one of the Public Libraries where the Patent Specifications are kept. —F. C.

**Glue, etc.**—B. W. (*Walthamstow*).—You should have no difficulty in applying the glue to the dovetails in the ordinary way with a brush. The smaller the work the smaller the brush, and, possibly, the greater the quantity of glue comparatively which may have to be cleared off afterwards. Your second question has revived my expectations of some day getting an inquiry about the correct amount of moisture necessary to stick a postage-stamp on an envelope, together with a request for a full description of the process, or some undertaking of similar difficulty. Run the saw at the speed you find most convenient. If you have steam, the speed will be different from what it will be if you only use foot power and a light machine. The quicker you run the saw the more work you will be able to accomplish in a given time.—D. A.

**Sheet Brass.**—TIMBRE.—You can get sheet brass of any length, breadth, and thickness you require at Messrs. Warner & Sons, Crescent Foundry, Cripplegate, London, and of Pontifex and Wood, Shoe Lane, London, E.C., and in Birmingham of Messrs. W. Tonks & Co., Limited. I expect the reason you have to pay high is for special sizes of sheets not usually kept in stock. With regard to your second query, you do not say whether the sheet brass to which you refer is "finished" or rough. If it is ordinary sheet brass as it comes from the makers, of course, polishing pastes are of no use, as they will not remove scratches and dents; you must get up a good surface with emery cloth of different degrees of coarseness till you have a smooth surface. It should then be burnished and rubbed up with a leather, and as to the colour of it, that depends on the mixing of the metal; no process of cleaning or polishing will alter that. Articles of cast brass can be to some extent altered in colour by dipping in aquafortis or a mixture of aquafortis and other acids, but this I expect would not be applicable to the articles you make. In reply to your third question, there are several lacquers or enamels of the kind you require. One is called 'Zapon;' it is of American origin, and it can be procured from the Frederick Crane Chemical Company, Newhall Hill, Birmingham. It is stated to be far superior in lustre, transparency and tenacity to lacquer, and much easier of application, and to be proof against damp, salt air, fly speck, etc. There is also the patent Silico enamel, which the advertisement states is used for protecting bright, polished, or plated surfaces, without altering the appearance, to be invisible, washable, and durable; not sticky or greasy to the touch. To be had in 1s. bottles of the Patent Silico Enamel Company, 118, Crawford Street, London, W. Messrs. Townshend & Thompson, brass founders and art metal workers, Ernest Street, Birmingham, advertise their goods as sent out covered with a perfectly transparent enamel of greater permanency than ordinary lacquer. But, whether it is the same as Zapon, or whether they would supply it to you, I cannot say, but a letter would no doubt receive their attention.—R. A.

**Brass Casting.**—SHOPMATE.—Plaster of Paris is not suitable for ordinary brass casting—proper venting being impracticable. It is used in type-founding. To cast brass you must mould in sand, and the best way is to get a small quantity from a local founder. Several articles would be required to give sufficient information to enable you to do brass casting; these will be forthcoming when some other sets of papers are concluded.—J.

**Veneer.**—A. W. (*Manchester*).—The ebony knife-cut veneer you will get from W. Daniel, 77, Church Street, Shoreditch, E.C.—A. J. H.

**Developing Prints.**—PHOTOGRAPH.—First prepare three solutions—one of neutral oxalate of potash, one pound, to three pints of hot water, slightly acidified with sulphuric acid: call this A. Another. Protosulphate of iron, one pound, to a quart of hot water, and add half a drachm of sulphuric acid: call this B. Another. Bromide of potassium, one ounce; water, two pints: call this C. These solutions keep well separately, and must be mixed just before use. To develop: In a suitable tray, place six ounces of solution A, one ounce of solution B, and half a drachm of solution C. Mix in order given, and use cold. After exposure, soak the paper in water till limp; then immerse in the developer, avoiding bubbles. The image should appear slowly, and should develop up strong, clear, and brilliant. When the shadows are sufficiently black, pour off the developer, and flood the print with water to which acetic acid has been added in the proportion of half a drachm to the pint; pour this off and repeat two or three times, using fresh acid water each time; then rinse well in pure water, and immerse for ten minutes in a fixing bath, made of three ounces of hyposulphate of soda to a pint of water. Wash for an hour or two in several changes of pure water, and dry. With regard to exposure, very much depends on the density of the negative and light. An average negative, held about 18 in. from a No. 4 Bray gas-burner shielded with ground glass, would probably require about ten or fifteen seconds' exposure. The exact time must be obtained by experiment. Some negatives are done in two or three seconds, some requiring as many minutes. As a rule, a thin negative gives the best result with bromide paper; very dense negatives are quite unsuitable.—D.

**Cycle Construction.**—A METAL WORKER.—This correspondent would like to see in WORK papers on Cycle construction, particularly the "Safety." Let him refer to WORK, No. 107, where there is a full description of how to make a "Safety" bicycle. As to cycle repairing, I shall continue to tell any inquirers all I can to help them on in putting to rights their own machines.—A. S. P.

**Simplex Dynamo.**—T. H. (*Farringdon Road, E.C.*).—The dimensions of the No. 1 Simplex dynamo solid armature, described on page 758, Vol. II. of WORK, are given on the same page in the "List of Dynamo Electric Machines—Simplex Type." It is 3½ in. in diameter by 2 in. in depth. —G. E. B.

**Gold Transfers.**—A NEW READER OF "WORK." —This correspondent will get the transfers from Iliff and Son, publishers of the *Cyclist* and *Photography*, 12, Smithford Street, Coventry.—A. S. P.

**Industrial Exhibitions.**—REX.—You cannot do better than watch the advertisements in the daily papers. All exhibitions are well advertised beforehand. There is one coming on at Glasgow.

**Glass Embossing.**—G. N. (*Stratford, E.*).—You wish to know if there is anything you can add to fluoric acid to give a ground appearance to etched glass, and you do not want to use the gas process. There is nothing I know of that you can add to the acid to give the effect you desire. The gas would do so, but as you do not want to use that, the only thing you can do is to grind it afterwards with powdered emery. If you wish for a very fine grain, get the finest flour emery, put it in water, let it

settle, then pour off the water gently, and use the top strata, which will be finer than the bottom, the coarsest grains settling first.—W. E. D.

**Camera Lens.**—F. H. (*London, S.E.*).—The lens is probably an old quarter-plate combination, but it is impossible to give any definite opinion without a careful examination. As to the size of camera suitable—probably a quarter-plate camera; but it is easily ascertained if the lens is fixed in one end of a box and a piece of ground glass with lines ruled upon it, representing the different sizes of pictures, is held so that the image from the lens falls accurately upon it. When the image is seen sharply defined, note must be made of the space covered. —D.

**Slide Rest.**—AXLE.—If AXLE wants a thorough good compound slide rest for a 5 in. centre lathe, he had better write to Mr. William Gladstone, Stafford, where he can get a set of castings for 8s. 9d.; or if he still desires to make his own patterns, he can procure a tracing half size for five penny stamps. —T. R. B.

**Taking Out a Patent.**—R. W. S. (*Leeds*).—The claims as sent would not be allowed, as they contain what would be held to be only coverable by a trade mark. If a provisional specification is to be put in, it requires to be very carefully considered and prepared both as to the title and the description, supposing it is intended to obtain a valid patent, and one that the law will support. If a provisional is lodged as the first step, drawings should not be included. In the complete specification, all that is recorded in the provisional and covered by the title may be enlarged upon, but no new part not covered by or included in either can be introduced without vitiating the patent. All must be strictly confined to what has been foreshadowed in the provisional. The article in WORK which R. W. S. should read and study is that contained in No. 44, Vol. I., page 694, and no protection in any colony or foreign country can be applied for or obtained in Great Britain. Each colony and foreign country has its own laws, rules, and regulations, independent of all or any in force here. The cost of a patent entirely depends on the amount of work in the shape of skill, knowledge, time, and ability required and called into action in preparing the documents, and doing all that is needed in a proper and efficient manner. A patentee must get his documents recorded in the Patent Offices of each country which has joined the convention before the expiry of seven months from the date of his application in Great Britain, if he intends to patent abroad. If an invention is patented only in Great Britain, any colony or foreign country may—*i.e.*, persons residing in it—manufacture and sell the same if the inventor has not protected his rights within the time specified. A valid patent can be obtained in America after the application for a provisional has been made here, provided the patentee protects his rights there within the time required by the convention, and sell the same when obtained. Of course it is to be assumed that R. W. S. has carefully ascertained whether his invention is novel, useful, and not in use or described before; otherwise he would only waste his time and money applying for and obtaining what would be of no good when patented, as the British Patent Office makes no investigation as to these points, but grants the patent entirely on the declaration of the applicant that he is the "true and first inventor," and that the invention is "not in use, to the best of his knowledge and belief." It is of the first importance for R. W. S. or any other intending patentee to be certain on this point, in order to prevent waste of money, time, and trouble, and experiencing the disappointment which inevitably attends on neglect of proper and needed precautions. Above all things, R. W. S. should avoid attempting to obtain a valid patent by his own unaided exertions. To do work of this kind as it ought to be done requires nearly a lifetime of practice and experience and extended practical knowledge and skill, which rarely, if ever, falls to the lot of inventors and would-be patentees to have acquired.—C. E.

**Carvings.**—J. C. (*Belper*).—If you want carving patterns for the decoration of ordinary household furniture, you will only be able to get them from some friendly carver who may be willing to exchange with you or sell you some, as there is no regular supply of them, nor, so far as I am aware, are any published for sale. If you only want small carving patterns for fancy articles, you will be able to obtain them from Harger Bros. or from Zilles. Those published by the former would probably suit you best.—D. A.

**Wheel.**—J. B. (*Tyldesley*).—You can make a lead wheel by casting from a pattern; you can make a wooden wheel, and glue and peg leather around it for buffing; and you can get an emery wheel from a score of firms—say, Sterne, of Glasgow; Lloyd, of Steelhouse Lane, Birmingham; or of any tool merchant.—J.

**Wheels.**—J. F. (*Leeds*).—You can always tell which is driver and which is driven, by bearing these two fundamental rules in mind:—(1) In a *simple train*, the pitch of the guide screw bears the same ratio to that of the screw to be cut as the number of teeth in the driving wheel bears to the number of teeth in the driven wheel. (2) In a *compound train*, the pitch of the guide screw bears the same ratio to that of the screw to be cut as the *product* of the number of teeth of the driving wheels bears to the *product* of the number of teeth in the driven wheels. It does not matter which of the driving wheels goes on the lathe mandrel. Certainly the driving wheels do not gear into one another. A driver gears into a driven, and in a compound train the second driver is on the same stud as the first driven. For taper turning, you swivel over the top slide of the compound rest.—J.

**Machine Design.**—T. W. (*Manchester*).—The best is Professor Unwin's "Elements of Machine Design," published by Longmans.—J.

**Steel.**—J. S. B. (*No Address*).—The best place that I know of for getting tool steel at reasonable prices is at Messrs. Pfiel, Clerkenwell.—J.

**Model Yacht.**—A. A. B. (*Brighton*).—I must point out that E. O. N. asked for directions for making a model yacht, whereas you ask for a design for same. I would explain that Fig. 1 herewith answers your wants. R is the rudder, which is exaggerated somewhat; M is the mainsail; F, the foresail; J, the jib; and T, the gaff topsail. In a breeze, a jib-headed topsail (shaped like the jib with no yard attached) is hoisted in lieu of T. The best plan as to sails is to get the boat built, sparred, and rigged, then hoisting the gaff into position: the sails are readily cut out in newspaper as patterns. Do not stretch the sails along their respective spars, but allow them to stretch with the wind, and pull out the slack from time to time afterwards, as required; and if the main and gaff topsails show any tendency to "belly," the upper sides may be hollowed slightly to flatten them. The jib should have a cord run along its foreside (like a piping cord), so as to take the strain in hoisting; and the jib must be hoisted tight. Your want No. 2 is sufficiently met in Figs. 2 and 4, at page 652 of No. 92, the overhang of counter being lengthened or reduced, according as the club rule under which the boat is raced enforces water-line or overall measurement; and as to your want No. 3, you will find the sections given at Fig. 2 herewith will, if followed, turn out a very presentable craft. *x x* give the midship section; 1 and 2 are placed about equidistant between *x* and the stem; 6 is under the counter; while 5 is just at the foreside of the stern-post; and 3 and 4 are placed about equidistant between *x* and 6. Finally, you will scarcely find two model yacht sailors agree as to the best form of hull, and to become a successful hand one must not be afraid of experimenting; and indeed, herein lies the chief pleasure of the pastime.—W. H. M.

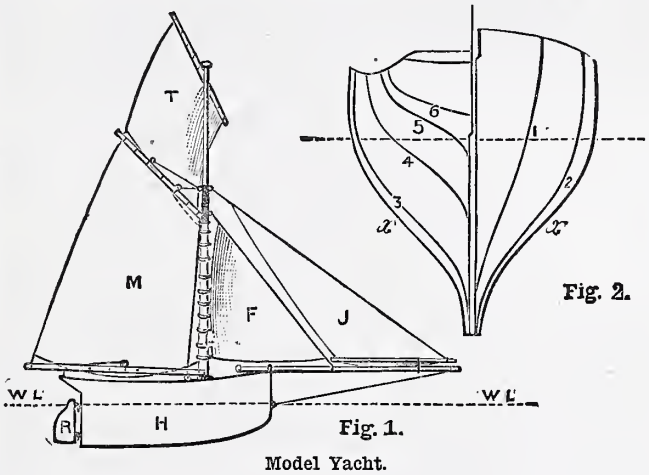


Fig. 1.

Model Yacht.

Fig. 2.

**Soap Making.**—D. W. (*Liverpool*).—An article on the above subject appeared in WORK, No. 103. It contains all the information you ask for.

**Bent Iron Work.**—IRONSIDES.—There is no particular instruction requisite, only to learn the art of bending graceful curves with the pliers, and holding them securely to one another with clips. It is a pretty branch of amateur work, requiring only a pair of tinmen's snips, and two or three pairs of round and flat-nosed pliers. The wire is cut from sheet iron of thin gauge. A very little practice will enable you to turn out neat work.—J.

**Unpickable Lock.**—APPRENTICE.—Try Chubb and Co., or any well-known lock-maker in London, for an unpickable lock.

**Books on Dynamo Construction.**—APPRENTICE.—"The Dynamo: How Made and Used," by S. R. Bottone, Wallington, Surrey, post free from the author for 2s. 6d.; "How to Make a Dynamo," by A. Crofts, Dover, Kent, price 2s., post free from the author; "Practical Dynamo Building for Amateurs," by F. Walker, price 2s. 1½d., post free from Iliffe & Co., 3, St. Bride Street, London, E.C.; "The Dynamo," by W. B. Esson, price 7s. 6d., Whittaker & Co, Paternoster Square, London; "Dynamo Electric Machinery," by Prof. Thompson, price 16s., Spon & Co.—G. E. B.

**Book on Electrical Engineering.**—APPRENTICE.—There cannot be said to be any *best* book on electrical engineering. The nearest approach to such a book is "Electricity in the Service of Man," published by the proprietors of WORK. "Electricity in Theory and in Practice, or the Elements of Electrical Engineering," by Lieut. Bradley, price 10s. 6d., published by E. & F. Spon, London, is also a useful book on the subject.—G. E. B.

**Electric Night Light.**—APPRENTICE.—Gassner dry cells are suitable for lighting up a 3 c.p. lamp at short intervals of not more than five minutes at a time occasionally during the night, but will soon run down if frequently used on intervals of fifteen minutes. An 8-volt lamp will require a battery of at least six large Gassner cells; these will cost 4s. 6d. each, and furnish current (for this purpose) for fifty hours; then they can be re-charged with current from a dynamo, and their power thus restored. —G. E. B.

**Model Gülcher Dynamo.**—APPRENTICE.—I should not advise you to attempt making a model of this type. The tracing you send is an excellent one, and the extracted data most suitable to accompany such a picture, but you would require working drawings of a reduced design to enable you to make patterns for the eastings, etc., and these I cannot make for you. Far better choose a Manchester or a Simplex as a model, and work to the instructions given in my papers on "Model Electric Lights," page 758, Vol. II. of WORK. A 360 Watt machine, giving a current of 60 volts pressure, would yield a current volume of 6 ampères, which would be sufficient to furnish 100 c.p. in electric light, and absorb a little over ½ h.p. The 5 ampère switch would therefore not have sufficient carrying capacity.—G. E. B.

**Barometer Tube.**—COCKER.—Gauge-glass tubes will crack in a similar manner after being polished inside with a wash-leather mop. The cause is probably due to an electrical condition of the glass, due to the friction of the leather pad. Use a brass wire instead of iron wire, and put a clip of brass wire in the end of the tube after cleaning it. Perhaps some reader of WORK will kindly suggest some other remedy. Do not make a hole in the wash-leather bottom of the cistern. If you do this to admit air, it will be ruined, as the mercury will come out through the hole. The atmosphere presses on the wash-leather, or "kid leather," and this presses on the mercury. As the barometer tube fits tightly into the wooden box, this is air-tight, and its upper part is a vacuum, when the tube with its column of mercury is fixed in position.—G. E. B.

**Electric Bell Wires.**—COCKER.—No. 32 B.W.G. copper wire is much too fine for use in the construction of electric bell coils. The smallest useful size is No. 24. Are you sure of the size sold you by the dealer? He must have been either a fool or worse. I do not say that this size cannot be used in constructing a bell, but it must be a very small one, and would need several battery cells to ring it. The wire is quite useless for the coils of a 5 in. bell. This size should have magnet cores 3¼ in. by ⅝ in., fitted with bobbins 3 in. by 1¾ in., and wound with No. 18 silk or cotton-covered copper wire. Use at least three cells of the largest Leclanché size as a battery.—G. E. B.

**Gold and Silver Solutions.**—G. V. (*Esclairmonde*).—To detect the presence of gold in a solution of cyanide of potassium, place in it a strip of clean bright zinc, freshly scoured. In a short time some of the gold will be precipitated on the zinc, and may be known by its colour. To detect the presence of silver in a solution of cyanide of potassium, place in it a strip of bright copper, freshly scoured. In a short time some of the silver will be precipitated on the copper, and may be distinguished by its well-known whiteness. To recover gold from its solution in cyanide of potassium, heat the solution, and drive off the water as steam until a pasty mass only remains. Dry this, and fuse it at a bright red heat in a fire-clay crucible. When the brown residue has cooled, digest it in nitric acid, and wash the brown powder on a filter with water. Dry this, and fuse to a button in a fire-clay crucible, using dried borax as a flux.—G. E. B.

**Polishing.**—W. D. H. (*Edinburgh*).—The cabinet to which you refer has probably been finished by what is known as ebonising, and your friend is, no doubt, quite correct in assuring you that it is not made of real ebony, which is very seldom used by cabinet-makers—so rarely indeed that it may practically be considered as non-existent. Any kind of wood can be ebonised, but those most commonly treated in this way are Honduras mahogany (haywood), American walnut, American white-wood, beech, and birch. None answers better than the first named. If the wood is sound, it does not matter if it is of bad colour or stainy. To ebonise, all you have to do is to stain the wood black, polish in the usual way, and then dull by dusting down with fine emery powder. The stain had better be bought ready-made. Darken the filling with black. A better colour can be got by using black polish than the ordinary kind. It is only necessary to put a little gas-black into the polish. Apply the emery powder with a brush or a soft cloth, and let the

motion be in one direction—with the grain—only. The powder soon removes the bright gloss from the surface of the polish. The bright parts are got by simply not rubbing them down. The composition for picture frames can be got from any gilder or picture-frame maker.—D. D.

**Hodge's Mitre Shoot.**—W. N. (*Winsford*).—Any large tool dealer—such as Melhuish, Fetter Lane, London; or Moseley, High Holborn, London—could supply you with one of these tools.

**Tricycle House.**—A. N. G. (*Bristol*).—A paper upon this subject appeared in WORK, No. 64.

**Transferring or Copying Printed Matter.**—G. M. (*Liverpool*).—There is a process which has been used for transferring the printed picture to white wood for ornamental purposes. The wood is varnished, and when so far dried as to be only very slightly sticky, the engraving is well pressed or rubbed upon it. The varnish is too dry to adhere tightly to the clean paper, but it adheres closely to the printing ink, which is, of course, of the nature of oil paint. The paper can be moistened and removed, but an impression of the engraving will remain on the varnished wood. However, if a part of the ink is taken away, the blackness and solidity of the original painting must suffer. Would not some photographic process be really better? When the printed matter is on one side of the paper only, I presume that a copy might be transmitted to sensitised paper without the aid of a camera; or, with a camera, producing a good copy under any circumstances would be easy.—S. W.

**Couch Scroll.**—KILDONA.—To make measurements of couch scroll clearer, perhaps the artist intends it to mean 2 ft. 8 in. from the floor to top of the scroll, which would be about right. The drawings are freehand. That from the top edge of box to top of scroll is about 20 in.: measured perpendicular, 16½ in. Nearly every couch made has a different pitch of scroll.

**Picks.**—JAMES.—I obtained my lock picks—which I find answer all ordinary purposes—from Messrs. Harding & Sons, Long Lane, London.—T. W.

**Chime Clocks.**—J. S. (*Edinburgh*).—The prices of chime clocks vary considerably, but the price of any ordinary chime bracket would be, in case complete, from £30 retail up to, say, £100, according to style of case, etc. I hardly know where the best place would be to get the movements only, but I should think Smith & Co., Clerkenwell; Thwaites and Reed, Clerkenwell; Evans, Birmingham; or Potts, Leeds, would supply them.—A. B. C.

**Irregular Watch.**—NOVOCASTREN.—I am doubtful if I can assist you much without seeing and examining your watch, but I am rather inclined to think that it may have become magnetised. Have you been in or near any place where a dynamo is, or anything else electrical? If not, have you at any time given the watch a blow or let it fall, and so cracked either jewel-hole or end-stone of the staff, or flattened the end of staff pivots? If neither of these has happened to it, then has the mainspring been broken or changed?—A. B. C.

**Clock Tools.**—A. B. X. (*Guildford*).—I do not think you can better either of these two—viz., Haswell & Sons, 49, Spencer Street, Clerkenwell; and Grimshaw & Co., 35, Goswell Road, Clerkenwell. From these I get nearly, if not quite, everything I require. For clock wheels, trains, and castings, I go to I. Mayes, 55, Red Lion Street, Clerkenwell. Also, I occasionally do a little (tools, materials, etc.) with Hunt & Son, 21, Ironmonger Street, St. Luke's.—A. B. C.

**Bicycle Wheel.**—SPRING.—Of course he must spring the fork wide enough to let one end free, when the other will pull out if the holes are not too tight-fitting on the shaft. The forks usually stand a considerable amount of spring outwards, and they have to be sprung in this way in order to get the wheel in.—A. S. P.

**Phonograph.**—F. W. B. (*Ardwick*).—The article on the Phonograph has not yet appeared. The promise given had nothing to do with Edison's latest instrument. Detailed instructions, with drawings, will be given, which will enable anyone possessing sufficient mechanical ability to make a phonograph. It would certainly be a "breach of patent," as you say, to make one of Edison's instruments for your own *use*. The cylinders are not on sale, neither are the instruments; they are let out at a very high rental.—W. D.

**Chronometer**—AUXILIARY asks me to give him a few hints regarding the construction of a chronometer detent for a bar movement. I do not clearly understand what is meant by "bar movement," but, in any case, I am afraid it is almost impossible on paper to say anything sufficiently lucid about the construction of a chronometer detent to be practically useful. A chronometer detent is the most delicate and exact piece of mechanism in the whole range of watch making, and it is difficult to learn how to make it even when side by side with a tutor. But to explain how to construct such a piece of work merely by describing the process in print is, I am afraid, almost out of the question. I take it for granted that AUXILIARY is acquainted with the shape and the purpose of a detent, and that he is anxious to make one himself. But I think he would be wise not to attempt to do so. It is the work of a chronometer maker, who is a specialist in this branch of the art, and it would be much more practical to send to a chronometer maker in case he requires a new detent applied to a watch. This, in fact, is what watchmakers of approved skill and experience usually do. It really requires a man who has all the appliances at hand and almost daily practice to construct a good detent. Of course, if AUXILIARY is a watchmaker, and in the course of his business has to handle job chronometers, he will frequently be face to face with little difficulties which, perhaps, he cannot overcome. If, therefore, he will specifically state any of these difficulties, I shall then be very pleased to supply him with any information concerning the case he presents for my consideration.—HERR SPRING.

**Rusty Milk Pan.**—A. D. (*New Cross*).—The defect in your pan of rust spots, causing holes in an almost new article, is unfortunately one that it is difficult, if not impossible, to account for; it is known in the trade as "pilling," or "rust spot." There was some considerable discussion on the subject in the *Ironmonger* some years ago, between makers and users of tin plates, as to the cause of this serious defect, but, as far as my memory serves me, there was nothing definite arrived at, except that the best brands of plates were as liable to it as the commoner ones. Milk is a non-corroding fluid, and as a rule, articles used in dairy work last a very long time, so that it cannot be from the action of the liquid. I should think myself that it is caused through there being rust spots on the iron before being tinned, and that a rusting action continues after the process of tinning, eating the iron away between the two coats of tin. I can detect a plate that will "pil"; the places are indicated by a few little marks like tiny pin-points. Select for your next bottom a perfectly smooth and brightly tinned plate, and have a good stout one; rejeet any that have little depressions in them, or the marks I have mentioned. Many ironmongers stock what are termed "perfect" or "prime" plates: these, being all selected singly, are certainly more likely to be free from defects than the others, which are termed "wasters," and with which the ordinary jobbing man repairs most articles brought to him. I do not see why you must have a new bottom every time you have a hole or two come; would not a tiny drop of solder over each hole meet your requirements, especially as your pan is only a counter pan, and gets no special wear or knocking about? As a final suggestion, try a thin *tinned* copper bottom: this will last a very long time indeed.—R. A.

## III.—QUESTIONS SUBMITTED TO CORRESPONDENTS.

**Preserving Ice.**—J. R. (*Middlesbrough*) writes:—"How can I preserve about half a ton of ice gathered here from a pond? I want to keep it until July or August next. I have at my disposal a wine-cellar 20 by 12 ft."

**Knitting.**—H. B. S. (*Lockwood*) writes:—"Will anyone tell me if the fancy check stockings which are usually understood to be hand-knit can be made by machine, and if so, by what machine?"

**Leclanché Battery.**—C. F. W. N. (*Forest Gate*) writes:—"Will any reader kindly inform me where I may obtain a Leclanché battery or any other small battery to work an alarum bell, and what it will cost?"

**Fan Covering.**—PHONO writes:—"I am cutting a fretwork fan, and shall be glad to be informed as to where I can get it covered."

**Regulator.**—W. P. B. (*Colnbrook*) writes:—"Can any kind reader of WORK instruct me as to making regulator for egg incubator?"

## IV.—QUESTION ANSWERED BY A CORRESPONDENT.

**Newspaper Cart.**—ESSEM writes, in reply to L. M. N. (*Liverpool*) (see page 765, Vol. II.):—"I send you herewith three rough designs for such a light conveyance as you ask for."

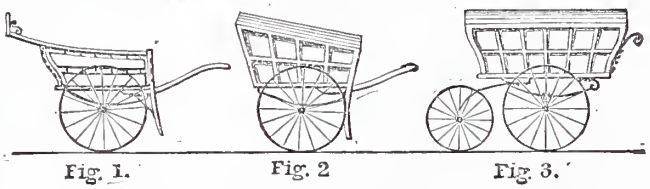

Fig. 1. Fig. 2 Fig. 3.

Newspaper Carts.

## V.—BRIEF ACKNOWLEDGMENTS.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—H. L. D. (*Rochester*); CHARLIE; S. T.; R. C. (*Sussex*); W. E. (*Liverpool*); V. S. (*Sheffield*); A. H. K. (*Birmingham*); J. R. N. (*London, N.*); CRANK; J. L.; J. B. C. (*Liverpool*); SCENERY; W. H. (*Hants*); AMATEUR; NOVICE; NEW ZEALAND; BELTING; T. J. (*Shemield*); PHŒNIX; W. W. J. (*Broughton*); X. Y. Z.; H. C. (*Whetstone*); A. S. W. (*London, N.W.*); J. B. (*Bury*); C. M. J. (*Perth*); I. S. (*Newcastle-on-Tyne*); BASSO PROFUNDO; R. B. (*King's Lynn*); J. W. (*Kendal*); G. P. (*Edinburgh*); A. F. M. (*Glasgow*); J. H. M. (*Beau Parc*); C. A. N. (*Wolverhampton*); SNOBBERY; A SNOB IN THE COUNTY OF DORSET; W. R. R. (*Carlisle*); J. W. B. (*Wakefield*); AMATEUR ELECTRICIAN; W. G. S. (*Manchester*); RED LINE; A. B. X. (*Guildford*); J. L. (*Holloway, N.*); R. C. (*Exeter*); R. A. F. (*Shepherd's Bush*); JOINER; H. K. D. (*South Shields*); W. C. S.; E. J. C. (*London, S.E.*); J. T. (*Nottingham*); G. M. (*Brixton, S.W.*); M. W. (*Manchester*); B. S. (*Acton, W.*); P. F. (*Manchester*).

## "WORK" INDEX.

An Index to the Second Yearly Vol. of WORK has been prepared, and can be obtained by order from all booksellers, price 1d. It is included in Part 24.

CHEAP EDITION. Price 9s.

**Electricity in the Service of Man.** A Popular and Practical Treatise on the Applications of Electricity in Modern Life. With nearly 850 Illustrations.

"All the useful applications of Electricity are described in its pages. In that respect it has no rival."—*English Mechanic.*

CASSELL & COMPANY, LIMITED, *Ludgate Hill, London.*

Price 2s. 6d.

**Numerical Examples in Practical Mechanics and Machine Design.** By ROBERT GORDON BLAINE, M.E. With an Introduction by Professor JOHN PERRY, M.E., D.Sc., F.R.S. Twenty-six Diagrams.

CASSELL & COMPANY, LIMITED, *Ludgate Hill, London.*

Price 2s.

**Elementary Lessons on Applied Mechanics.** By Sir ROBERT STAWELL BALL, LL.D., Author of "The Story of the Heavens." With 140 Questions for Examination.

CASSELL & COMPANY, LIMITED, *Ludgate Hill, London.*

NEW AND ENLARGED EDITION, price 1s.; or in cloth, 1s. 6d.

**Photography for Amateurs.** A Non-Technical Manual for the Use of All. By T. C. HEPWORTH. With Illustrations.

CASSELL & COMPANY, LIMITED, *Ludgate Hill, London.*

WORK

*is published at La Belle Sauvage, Ludgate Hill, London, at 9 o'clock every Wednesday morning, and should be obtainable everywhere throughout the United Kingdom on Friday at the latest.*

# A WONDERFUL MEDICINE.

# BEECHAM'S PILLS

Are universally admitted to be worth a Guinea a Box for Bilious and Nervous Disorders, such as Wind and Pain in the Stomach, Sick Headache, Giddiness, Fulness and Swelling after Meals, Dizziness and Drowsiness, Cold Chills, Flushings of Heat, Loss of Appetite, Shortness of Breath, Costiveness, Scurvy and Blotches on the Skin, Disturbed Sleep, and all Nervous and Trembling Sensations, &c. &c. The first dose will give relief in twenty minutes. This is no fiction, for they have done it in countless cases. Every sufferer is earnestly invited to try one Box of these Pills, and they will be acknowledged to be

**Worth a Guinea a Box.**

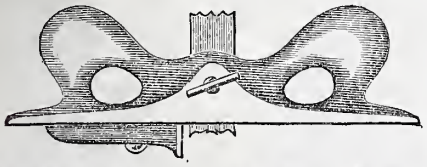
FOR FEMALES THESE PILLS ARE

"A priceless boon, a treasure more than wealth; the banisher of pain, the key to health."

These are FACTS testified continually by members of all classes of society, and one of the best guarantees to the nervous and debilitated is,

***BEECHAM'S PILLS have the Largest Sale of any Patent Medicine in the World.***

Prepared only by the Proprietor, T. BEECHAM, St. Helen's, Lancashire, in Boxes 9½d., 1s. 1½d., and 2s. 9d. each. Sold by all Druggists and Patent Medicine Dealers everywhere. *N.B.—Full Directions are given with each Box.*



## NEW HAND-BEADING TOOL,

which is accompanied by six irons, Beads, Reeds, Quirks, Rebates, and Hollow and Fancy Reeds. The appliance itself is of japanned iron with a bright front. Its extreme length is about 5¼ in.

POST FREE, 2s. 3d. 200 Page Catalogue, 700 Illustrations, by post, 6d.

MOSELEY & SON, 323, HIGH HOLBORN.

CASSELL & COMPANY, LIMITED, *Ludgate Hill, London.*

# FRETWORK FOR AMATEURS OF BOTH SEXES AND ALL AGES.

Eclipse Design, No. 102.

Wall Bracket. Price 5d.

THE MOST PROFITABLE AND FASCINATING OF ALL HOME PASTIMES. EASILY LEARNT.

J. H. SKINNER & Co. having *Dissolved Partnership*, are offering their *Enormous Stock*, including 250,000 FRETWORK PATTERNS and 100,000 ft. of Solid and Three-Ply FRETWOOD, Veneers, &c.; 1,000 Gross of FRETSAWS, besides an immense quantity of TOOLS, OUTFITS, &c., as a special inducement to their customers to order at once.

**4,500 1s. Books of Fretwork Patterns**, each containing Twelve Large Sheets, beautifully lithographed, none of which would be sold retail at less than 2d., and many at 3d. and 4d. each; also

**1,200 2s. 6d. Books of Fretwork Patterns**, containing Twenty Sheets, 19 in. × 12 in., of new designs, many of which would retail at 6d. each. These Books,

**£375 in Value, will be GIVEN AWAY.**

Amateur customers ordering 5s. worth of designs from Catalogue will be presented with one of the above 1s. Books. Those ordering 10s. worth will receive a 2s. 6d. Book.

**An Allowance of 10 per Cent.** *in goods* will be made on all mixed orders for Wood, small Tools, Saw Blades, and Designs, amounting to 10s., and **15 per Cent.** on orders amounting to 20s. and upwards. NOTE.—*This reduction does not apply to Treadle Machines.*

N.B.—A SPLENDID OPPORTUNITY FOR BEGINNERS.

**Complete Fretwork Outfit**, comprising 12-inch Steel Frame, Forty-eight Saws, Awl, File, Four Designs (with sufficient Planed Wood and 1s. Handbook on Fretwork). **An Archimedian Drill**, with brass handle and Three Bits, will be **SENT GRATIS** with each Set. Post free for 3s. 6d. Outfits on Card, 1s. 6d. and 2s. 9d.; post free. 6 ft. 2nd quality assorted planed Fretwood, 1s. 9d.; post free, 2s. 6d. 12 ft. ditto, ditto, 3s.; post free, 4s. 3d.

SKATES!!!—EVERY PAIR WARRANTED.—Sizes, 7½ in. to 12 in. No. 1, Unpolished Beech, 10d. per pair. No. 2, Polished Beech, 1s. 6d. per pair. No. 5, "Acme" pattern, all steel, 3s. per pair. No. 7A, "Caledonia" pattern, self-adjusting, one screw fastening the whole skate, the best principle, 6s. per pair. No. 8, Metal frame, with strap complete, 1s. 9d. per pair; postage, 5d. per pair. These are not rubbish; we warrant every pair.

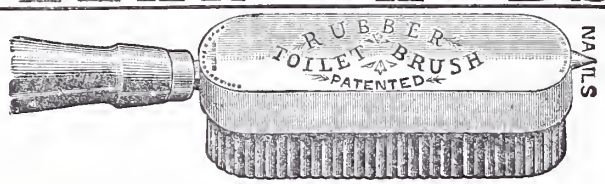
NEW CATALOGUES of Machines, Designs, Wood, Tools, etc., with 600 Illustrations and full instructions for Fret-cutting, Polishing, and Varnishing, price 4d., post free. A Specimen 6d. Fretwork Design **SENT GRATIS** with each Catalogue; also a List of Designs, Outfits, Tool Chests, etc., at Greatly Reduced Prices to clear.

N.B.—All orders *must* be accompanied by remittance. APPLY—

**J. H. SKINNER & CO.,** Manufacturers of Fretwork Materials, W Department, *EAST DEREHAM, NORFOLK.*

*Kindly mention this paper when ordering.*

# CLEAN HANDS!



*For Everyone, no matter what the Occupation.*

Nothing has ever been invented that will so thoroughly cleanse and whiten the hands as our **Rubber Brush.** Used with soap and water, it will remove all kinds of stains, **Ink, Tar, Iron Stains,** and **Paint,** yielding easily to it, without injuring the most delicate skin, as is done by using pumice stone, bristle brushes, &c.

Price 1s Larger Size, price 2s.

We are also the makers of BAILEY'S CELEBRATED RUBBER BATH and FLESH BRUSHES, price *5s.* each; COMPLEXION BRUSHES, price *3s. 6d.* each; RUBBER TOOTH BRUSHES, price *10d.* and *1s.* each; and TEETHING RINGS, price *5d.* each.

*To be had from all Chemists and Dealers in Toilet Goods, or will be sent, post free, on receipt of price by the Manufacturers,*

DAVID MOSELEY & SONS, 14, Aldermanbury Avenue, London, E.C.; Ardwick, Manchester; and 57, Miller Street, Glasgow.

# WORK

## An Illustrated Magazine of Practice and Theory

FOR ALL WORKMEN, PROFESSIONAL AND AMATEUR.

[*All Rights reserved.*]

VOL. III.—No. 110.] SATURDAY, APRIL 25, 1891. [PRICE ONE PENNY.

Figs. 1, 2, 3, 4.—Designs in Wood Carving for Frame of Butter-Dish.

Fig. 6.—Design for Centre of Panel, etc. Figs. 7, 8.—Designs for Corners of Panels.

DESIGNS FOR FRAME OF BUTTER-DISH AND OTHER ORNAMENTAL WORK IN WOOD CARVING.

## A BUTTER-DISH, AND OTHER DESIGNS FOR WOOD CARVING.

BY W. H. GRIMWOOD, INSTRUCTOR TO THE SCHOOL OF WOOD CARVING, SOUTH KENSINGTON.

DESIGNS FOR BUTTER-DISH, MEDALLION, AND SPANDRELS, WITH INSTRUCTIONS.

THERE are few arts that are more fascinating in themselves, more useful for decorative purposes, or better suited to the requirements, power, and resources of amateur wood workers of either sex than wood carving; and it is *par excellence* an art that women can take up, and in which they may attain considerable proficiency. I think I may assume without fear of contradiction that every amateur who takes up any manual art likes to have the work of his or her hands, as the case may be, on view as frequently and prominently as possible, and that to this end, designs that are applicable to the elaboration of household furniture, or the ornamentation of articles used on and for the table, are perhaps more acceptable than any other. With this view I have supplied, at the Editor's request, four designs for butter-dish frames, or wooden discs or platters, hollowed out in the centre to a sufficient extent to receive and hold a shallow glass dish for butter, to be obtained at most shops in which glass and earthenware are sold.

Of these designs, two are arranged on conventional lines, or, in other words, exhibit a natural object—in this case the buttercup and its foliage—conventionally treated; a third, a seventeenth century design, and the fourth a design in Italian style. In treating the butter-dish, the designs for which it must be understood are confined to the circle in which are placed Figs. 1, 2, 3, and 4, the design selected having to be carried in continuance of the portion given, right round the sloping edge of the dish, care must be taken, first, to turn, or get turned, a disc suitable for the purpose in view, in accordance with the section given in Fig. 5; and having obtained this, to ground to section given for carving very slightly at the sides and deepest in the centre, or the effect will not be so good. Lime or sycamore may be the material used for the dish, or, better still, holly or Italian walnut. Unlike bread platters, the frames do not require washing, which spoils the colour of the wood. The glass, being loose, can be removed whenever it is necessary to wash it, and a brushing with beeswax only is all that is required to keep the frame in order.

As the Editor has a deeply rooted objection to anything in the form of waste, whether of space in a page of the Magazine or otherwise, and strictly charged me to avoid any indiscretion of the kind, I have given in the space occupied by the glass in the butter frame a design which has no connection whatever with the butter-dish itself, and which is intended as a medallion for the centre of a box-lid, drawer front, panel, etc. This subject, which is shown in Fig. 6, should be grounded out to the depth of $\frac{1}{4}$ in., or carved in high relief. Amateurs must ever bear in mind that the higher the relief the greater will be their difficulty, unless they understand modelling. I may remark that all grounds may be stamped, punches in different patterns being supplied for this purpose.

The designs given in Figs. 7 and 8 are suitable for corners of panels, or may be utilised—as indeed may all the designs—for *repoussé* work. The whole as placed in the page can be used for a square panel, one design, as a matter of course, being used for the four corners, and one of the four designs given for the ring encircling the central medallion. Moreover, spandrels should be selected to suit the conventional or natural design selected for the ring surrounding the centre.

Further, the wood carver must understand that the same designs will apply, with necessary modifications, for borders, frieze, uprights, and mouldings, flat or on the round. If flat, the ground should be of the same depth all through. Lastly, they may be enlarged to suit the requirements of wood carvers to any size, due care being taken to preserve the proportion between the different parts of the designs. A little tasty knowledge of drawing and skill in adaptation is all that is necessary to secure their successful application to the purpose in view.

## ELECTRO-GILDING BROOCHES, CHAINS, RINGS, ETC.

BY GEORGE EDWINSON BONNEY.

IMPERFECT ELECTRO-GILDING—HOW TO CLEAN THE TRINKETS BEFORE GILDING THEM—DOCTORING SOLDERED JOINTS—HOW TO MAKE AN ALKALINE COPPERING SOLUTION — USE OF THE COPPERING SOLUTION — SCRATCH-BRUSHING AND FINISHING ELECTRO-GILT ARTICLES—POLISHING ELECTRO-GILT TRINKETS.

*Imperfect Electro-Gilding.*—We may take a brass ring from a man's finger, and, seeing that it is bright and clean, conclude it will not need cleaning before hanging it in the gilding bath. We therefore merely wipe the ring with a scrap of rag, tie a bit of copper wire to it, and hang it in the gilding bath. In a few moments it has received a coat of gold all over, and bears the appearance of a golden ring. We then rinse it in warm water to free it from the cyanide salts, wipe it dry with a rag, and hand it back to the wearer, gilded. This looks very well at first sight, and vast numbers of brass rings thus gilt are sold by cheap Jacks to gullible youths and maidens. Rub the ring a little with the palm of the hand. The very thin coat of gold can be thus rubbed off in a few moments, leaving the bare brass plainly visible. All trinkets may be thinly gilt in a similar manner, and the thin coat of gold can be as easily rubbed off. If the ring or any other similar article is left in the gold bath for a few minutes, it will take on a brown coat instead of one having a golden tint. This brown coat is merely the matt appearance assumed by electro-deposited gold, and this will entirely disappear on brushing the coat with a brush of fine brass wire kept lubricated with stale beer. But on brushing in this way an imperfectly cleaned ring as it comes from a person's finger, we may notice that the ring assumes a brassy appearance, because the gold went on loosely over the sweaty parts of the ring, and these loose particles of gold were readily detached from the imperfectly cleaned spots by the wire brush, because they did not adhere to the brass, but only to the film of dirt on the brass. This non-adherence of electro-deposited coats becomes more apparent with thick coats than with thin ones. To get a perfectly adherent coat of electro-deposited metal, we must thoroughly clean the surface on which we intend depositing the coat. Let the ring, or brooch, or pin, or coin appear to be ever so clean to the eye, it must have contracted a trace of animal grease, or sweat, if it has been handled or worn, and this film of animal matter must be taken off before we can deposit a coat of adherent metal on the article.

*Cleaning the Trinkets.*—All animal matter, such as grease, oil, and sweat, may be loosened from the surface of metal by boiling it in a solution of strong alkali, such as soda, potash, or ammonia. A strong solution of washing soda may be used if nothing better can be obtained. Pearlash is a better cleanser; American pearlash, or potash, is still stronger; and the best cleansers (in general use by professional platers) are commercial caustic soda and caustic potash. A piece of either of these, about the size of a walnut, dissolved in half a pint of hot water, will be enough to clean a dozen or two of small trinkets or chains. First dissolve the potash or soda in hot water, then string a few trinkets on about 6 in. of No. 20 or No. 22 copper wire, and swill the bunch for a few minutes in the hot liquor. Transfer from the hot caustic solution to some clean warm water, and well rinse the trinkets in this, to clear off the loosened grease. When the caustic liquid is cool, put it in a closely stoppered bottle to exclude the air, and thus preserve it for future use. After the grease has been loosened, if there is no corrosion on the article, it must be briskly brushed with a little whiting, or prepared chalk, or finely powdered pumice, again rinsed, then hung in the gilding solution to receive its coat of gold. If the trinkets are corroded, the corrosion must be removed in a pickle made of two parts sulphuric acid, two parts water, and one part nitric acid, after which the articles must be rinsed in clean water. Chains of a strong pattern may be rolled up in a mass between the two hands with a little whiting, and rubbed until polished; but those of more delicate construction may not be treated in this way, but must be carefully brushed. Filigree work will require very careful treatment in cleaning, and the gold should be deposited on it with low battery power, to prevent browning the deposit, since it cannot be well brushed bright afterwards. Long chains of a delicate pattern should be threaded on a long thin copper wire passed through the links at intervals of from 2 in. to 3 in., or the wire should be wound spirally around the chain, to assist in conducting the current to all parts equally. Ear-ring and brooch pendants made of metal beads strung on silk should be suspended in a small basket of platinum gauze, in order that the beads may be placed in connection with a conductor of electricity, since silk will not conduct the electric current. This class of goods should not be put in the caustic solution, as this will dissolve silk, and cause the beads to drop off. It is also important to note here that all trinkets containing hair, photos, and other material likely to be injured by the hot gilding solution, must not be put in the caustic solution until the hair, photo, etc., has been removed. It is also advisable to remove glass and stones liable to injury from this cause, and to re-set them when the work is finished. Trinkets made of aluminium only will not receive a coat of gold, but will dissolve in caustic solution and in the gilding solution. The brush used in brushing articles before gilding may be an old, but clean, tooth-brush, or any clean brush with stiff bristles.

Whilst finishing the articles, we shall note the condition of their surface. If this has been scratched, or dented, or bruised, or pitted with corrosion before it was taken in hand to be gilded, the marks of injury cannot be

obliterated by polishing and burnishing afterwards. All such blemishes must be removed before the articles are cleaned, if they are to be removed at all, and this can only be done by hand, either by pressing out the dents with suitable pieces of wood, or removing the scratches with a fine file and burnishing the filed spot. All repairs must be done first, as it will be difficult to repair electro-gilt goods when finished.

*Doctoring Soldered Joints.*—If there are any joints made with soft solder, these will be difficult to coat with gold. If they are small, they may be doctored up in the following manner :—Get a piece of blue-stone (sulphate of copper) about the size of a broad bean, wet it, and rub on the soldered joint for a minute or so, then touch the joint with a piece of bright iron or steel. Both the iron and the joint will take on a coat of copper and cover the solder. Rinse the joint in clean water, and hang the article in the gilding solution, when it will take a coat of gold.

If there are several soldered joints or much soft solder about the article to be gilded, or if it is desired to coat a pewter medal, lead cast, zinc ornament, piece of tinned iron, or article composed wholly or partly of iron, tin, lead, or zinc, it will be advisable to first coat it entirely with copper in an alkaline coppering solution, made up in the following manner :—

*Alkaline Coppering Solution.*—Dissolve one ounce of copper sulphate (blue-stone) in one pint of hot rain-water. Add strong liquid ammonia to this, in small quantities at a time, and stir well between each addition of ammonia until the green precipitate first formed by the ammonia has all dissolved, and the liquid assumes a beautiful blue tint. Then add cyanide of potassium dissolved in water until the blue tint disappears, and the liquid has the appearance of old ale. It should now be heated to boiling point; then set aside to cool in the open air, and not be used until the next day. At least three cells of a battery will be needed to deposit copper from this solution, and perhaps four cells, arranged in series, may be required to force the copper on a soldered joint; but the copper thus deposited will be firm and adherent, and may be polished. This is not the case with thin coats of copper deposited from acid solutions of copper. Use a piece of good copper, such as electro-type copper, as an anode in the coppering solution. If a crust of green salt forms on this whilst working, add a little liquid ammonia to the solution; but if a blue crust forms on the anode, add a little cyanide of potassium to the solution. A mere film of copper will be all that will be required on the article to protect it from the action of the gilding solution. If the film does not go on evenly in a few minutes, take the article out of the bath, and briskly brush it with a brush made of brass wire, then return it to the coppering solution. This solution may be worked cold or hot, as may be desired; but the deposit is brighter from a hot solution than from a cold one. It is not only used in coppering articles to be gilded, but also to coat iron, tin, zinc, lead, pewter, and similar metals, before they are silver-plated, since silver will not adhere to those metals. It is also useful to give an 18-carat gold appearance to gilded or pure gold goods. This is done by merely flashing a film of copper over the surface when finished, then flashing a film of gold on this, rinsing at once in hot water, and drying off in clean sawdust. By careful working in this way, a clever workman can get any desired tint of gold on the surface.

*Finishing Electro-Gilt Articles.* — On taking strongly gilt articles out of the electro-gilding solution, they will be found to be coated with a brown powder. This powder is finely divided gold in a crystalline condition, the mass of crystals absorbing, instead of reflecting, the light. To remove this brown appearance, the articles are briskly brushed with a brush made of fine brass wire speeially drawn for the purpose, and named scratch-brush wire. Scratch-

Fig. 4.—Scratch-Knot made of Scratch-Brush Wire.

brushes are made up in various forms, to suit the kind of work to be brushed by them; but the usual form of the ordinary scratch-brush is that of a small boxwood cylinder with bunches of wire sticking out on all sides. This is mounted on the spindle of a lathe, and revolved at a high rate of speed, whilst the work to be scratch-brushed is held to the brush by the workman. The ends of the brass wires wear down the points of the gold crystals, and render the whole surface smooth. To prevent the brass from wearing off in the shape of dust and cutting the gold coat, the brush is kept lubricated with stale beer, and is covered with a hood, to prevent the lubricant from being splashed over other things in the workshop. When a plater has not a suitable lathe. the scratch-brushes are made like narrow plate-brushes or a tooth-brush with a wooden back, and are manipulated by hand. Amateur platers and gilders with small means are content to use scratch-knots made by themselves out of bunches of scratch-brush wire, as shown at Fig. 4. The wire is sold in knots: *i.e.*, small hanks, in three grades—heavy, medium, and fine—at prices ruled by the market price of brass wire. The fine wire is most suitable for gold work. Get a knot of fine scratch-brush wire and a few yards of No. 20 soft copper wire. Fasten one end of the copper wire to a nail or hook driven in a wood post, lay the hank of brass wire on the other end of the copper wire, and wind this tightly around the hank until all the middle of the hank has been covered with the close coils of copper wire, then tuck in the free end, and fasten it off. Next cut off the loops at each end with a pair of sharp shears or with a sharp chisel, whilst resting the loop on a block of wood, and thus form two brushes, one at each end. First rub the freshly-cut ends on a rough stone, to dull the points of the wire before using the brush on an electro-gilt surface. When the ends are too much burred by use, cut them off with a sharp chisel, and unwind the binding wire a few coils at a time, as needed, when the brushes wear short. With even such scratch-brushes as these, some good work can be done by hand, but it can be done more expeditiously with a revolving scratch-brush. Rest the work on a sloping piece of board over a vessel placed so as to catch the drips of stale beer, and work the brush from left to right, away from the workman, going over all the surface until all the brown appearance has been removed. Do not leave any of this in the crevices.

Lastly, rinse the work in warm water, and dry it in hot boxwood sawdust. Then polish with dry rouge on a plate brush, or burnish with highly polished steel burnisher, or one of highly polished bloodstone, using newly made soapsuds as a lubricant.

## THE VIOLIN: HOW TO MAKE IT.

BY J. W. BRIGGS.

SPECIAL TOOLS — PURFLING GAUGE — KNIFE — ROUTER—IRON CRAMPS—PLANES—APPLIANCE FOR BENDING RIBS—THICKNESSING GAUGE—STEEL SCRAPERS — HAND SCREWS — SPRING DIVIDERS, ETC.—CARVER'S SCREW—FILES AND GOUGES—JOINTING — TRUEING UP—MARKING BACK AND BELLY FOR RIBS—BENDING RIB STRIPS—GLUING RIBS—PLANING DOWN RIBS —MARKING BACK AND BELLY FROM RIBS—SAWING OUT BACK AND BELLY.

**Special Tools.**—In addition to the ordinary tools which are found in any joiner's shop (both professional and amateur), such as smooth plane, trying plane, saws, chisels, and the like, there are some special tools which would not be found there, and of which I will give a short description; but from the illustrations my readers may gather, perhaps better than from any description I might give, the manner in which some of these things are "fixed up."

*Purfling Gauge.*—The purfling gauge or cutter (A, Fig. 5) is a steel shell 4½ in. long by ¾ in. broad and ⅜ in. thick, with a projecting end half an inch long and $\frac{3}{16}$ in. in diameter; carrying a brass roller, which brings the thickness to ⅜ in. Half an inch from the bottom of the shell are two thumb-screws, one in each side; these are for adjusting and fixing the steel blades or cutters which run longitudinally through the instrument. I have ground the cutters in my gauge to "spear" points, and they answer very well.

*Knife.*—B is a knife such as is sold by stationers for erasing, but is ground to a long keen point. Two or three of these should be at hand; they are used for deepening the groove in which to lay the purfling, for trimming the sound holes, and many minor purposes, and should be kept as sharp as the proverbial razor.

*Router.*—The router (C) is a small bent chisel with which the piece marked by the purfling tool is taken out.

*Iron Cramps.*—Two forms of iron cramps are shown in D and E; six of the smaller are required for fixing the ribs on the model. F is a cramp which is sold by the dealers for fixing the back and belly to the ribs. G is one of my own design and make, and is, I consider, a great deal better than F. It is lined with cork on both the inner sides, and cannot possibly injure the most delicate instrument. The small cramp (P) is used for fixing linings in the waists; the other linings need no cramps.

*Planes.*—I is a small oval iron plane, with toothed blade, slightly round both in length and width. J is a similar plane, but with flat bottom. This is the most useful little tool for a number of purposes.

*Appliances for Bending Ribs.*—The apparatus for bending ribs (K) is of totally different construction to the one generally used; it is a piece of ¾ in. iron pipe, cut open all the length, and is heated by gas, as the illustration shows. The tube is fixed in an iron vice, and the gas heater is suspended from it by wires passing round each end of the tube.

*Thicknessing Gauge.* — The thicknessing gauge, or automatic measurer, is one of the most important tools in a fiddle-maker's "kit"; the one here given (L) is my own make, but was, like the bending apparatus, invented by my esteemed tutor, Mr. Wm. Tarr, of Manchester, now in his eighty-third year, and who is, I understand, the oldest living English violin maker, three of his 206 double basses having been made in 1829.

This gauge is extremely simple in its action, gives the most accurate measurements, and is not likely to get out of order. The small point of the gauge being held lightly underneath the back or belly, the thickness of which you desire to know, the ivory rule, the point of which traverses the surface, shows it at a glance in thirty-seconds of an inch.

*Steel Scrapers.*—M and N are steel scrapers, having one flat edge and three different round ones. The edges should be ground square across, the scraper placed edgeways in a vice, and sharpened by drawing the polished back of a gouge, or a proper "scraper sharpener," along the edges, at an angle of about 60°. A scraper sharpener is a piece of ½ in. round polished steel, and is fixed in an ordinary tool handle. When the scrapers become dull, draw the sharpener flat along the sides; this turns the "burr" to the edge again, then sharpen them in the vice as at first.

*Hand Screws.*—Hand screws (O) are often wanted; two or three sizes should always be in the work-room.

*Spring Dividers, etc.*—At Q is shown a pair of spring dividers, which are used for measuring distances very finely. The spring callipers (R) will be very useful, especially when finishing the neck. A pair of strong steel compasses (S) must be obtained. Never use the dividers for any purpose for which the compasses are intended.

*Carver's Screw.*—The point of the carver's screw (T) is to be firmly screwed into a carving block, and the stem passed through a hole in the bench, underneath which the wing nut is screwed on the stem. The carving block may be turned in any position, and, by tightening the nut, instantly made fast again.

*Small Square.*—A small square (U) is an absolute necessity, being in frequent requisition for such purposes as squaring the rib ends, testing the truth of blocks, etc.

*Fine-Toothed Plane.*—A fine-toothed plane, such as cabinet makers use for veneering, is frequently required, more especially if you use sycamore, which is strong in "figure."

*Files and Gouges.*—Several half-round files, different sizes, and of varying degrees of fineness, will be necessary, as also the "omnipotent" *gouges*, without which we cannot possibly get along. The "sweeps," or curves, given in Fig. 5 will be sufficient for our requirements, but a fiddle maker, it may be said, cannot have too many kinds of gouges.

*Oilstones.*—The oilstones for sharpening the gouges, both inside and outside, will, of course, be essential, as well as a good oblong oilstone set in case for sharpening plane knives and chisels.

*Shell Bits, Cutting Gauge, etc.*—Some violin makers use, for cutting the circular extremities of the sound holes, steel cylindrical shell bits, with diameters of ¼ in. and $\frac{5}{16}$ in. respectively. These holes may also be bored by the same sizes of centre-bits, but great care must be taken not to use too much pressure, as the sound holes lose much of their beauty if the sharp corners be broken off. A cutting gauge, for reducing the edges of back and belly to their proper thickness, and a slightly tapered shell-bit for boring the peg holes in the handle, will also be wanted.

**Jointing.**—We have now all the wood, models, and tools ready, and can commence our work by jointing the back and the belly, the pieces for which should be cut through as at B, Fig. 1 (page 4, Vol. III.); the insides of each piece should be planed quite true—*always plane the back across the grain*, otherwise you will jerk pieces out of it; then placing the true side downwards on the shooting board, with the trying plane make along the thick edge a perfectly square joint. This, to an unpractised hand, will be a matter of great difficulty, and an amateur would be well advised to get this process done by a cabinet maker who is accustomed to making fine joints. There is so little wood to spare, that if you should be so unfortunate as to make a bad joint you may not have room to remedy the defect. When both pieces are planed so true that you cannot see between them when placed together and held up to the light, hold both edges before the fire till quite warm, then fasten one piece in the bench vice with the planed side towards you; place the other piece with the true edge touching it, and very quickly go over both edges with fresh glue, very hot; now put the loose piece in position, and rub it slowly backwards and forwards, pressing firmly the while. When you have rubbed out as much glue as possible, which will be known by the amount of suction that ensues, and the pieces are quite even, sponge the joint both sides with hot water and remove the jointed piece from the vice; put it aside to set, and proceed to joint the other pieces. Whilst the back and belly are laid away to harden, take the inside model, and into each of the six recesses glue a piece of the 1 in. pine, width to suit, and rather longer than the depth of model; use only a small quantity of glue for the back of each block, as they will have to be forced out again when the ribs are finished; but for safety, cramp them into position with your iron cramps, and put the whole in a warm place to dry. After your joints are thoroughly hard (twelve hours at least should be allowed for this purpose) you must plane the flat sides of each piece quite true every way—lengthwise, crosswise, and diagonally.

*Truing up.*—For "truing up" the back, I use a plane of the same size as a "jack" plane, but bearing a coarse toothed iron, almost vertical; this was made to my own drawings by Varvill, of York; and if any reader wishes to have a similar one, I will supply details. For truing the belly use the trying plane.

*Marking Back and Belly for Ribs.*—The back and belly are now ready for marking from the ribs, and as these are not made, we must get them together.

Take the inside model into which the six blocks have been glued, and plane these down to the level of the model, but take care not to injure the latter in doing so. With a straight-edge continue the centre lines on the model, across each of the end blocks. Place the inside pattern to the centre line, and even with the model all round, next carefully trace the outline on the blocks; now turn the pattern and mark the other blocks in the same way. This done, write on each block, inside the marks, figures corresponding with those on the model, and repeat the whole process on the other side. With gouge No. 4 cut out the hollows in the insides of waist blocks; if you find that the wood is cutting inwards, turn the model over, and cut from the other side. Do not cut within the marks, and carve only the *insides* of waist blocks at present. *Make twenty small cuts rather than one too deep.* You should now fix the model edgeways in a wood vice, as you did when trimming it up after being sawed out, and, with the round side of a file to fit the sweep, take out all the inequalities which may have been made in carving, and make the hollows square across. The filing gives a better gluing surface for attaching the ribs.

**Bending Rib Strips.**—The next operation is to prepare the rib strips for bending. With one of the iron cramps fasten one of the strips by its extreme end to the bench, and place a small piece of wood or cork under the cramp, so that it will not damage the rib; and with the veneer plane work from the cramp to the end of rib, and take off the rough part of the wood. Now loose the cramp, turn the rib end for end, and plane the part which the cramp prevented you getting to previously. When all the strips have been treated in the same way, fix them on the bench again, and with a flat scraper, which must be very sharp, take out all the plane marks. Use the scraper diagonally, to cross the figure of the wood.

Divide the strips with a sharp knife, and the square into lengths of 5½, 7½, and 9½ in. One strip will make two top or 7½ in. ribs; the other two will each make one bottom and one waist rib. The next process is one which demands both steadiness, care, and patience, as accidents are very likely to happen, and another rib may have to be planed up. Fix the bending apparatus (K, Fig. 5) in an iron vice, attach an india-rubber tube from the gas to the heater, and light the gas, but observe that it does not light at the wrong place. Turn the gas very low, and when the tube is sufficiently hot to scorch very slightly a piece of paper held on it, the ribs may be bent as shown in Fig. 6.

Begin with the waist ribs, and make sure that the figure of all the ribs matches in inclination; it is better to mark each rib to the blocks before bending any of them. Do not hurry the bending; use only gentle pressure; when hot enough, the ribs may be bent any way you wish. It is safer to have near you a small bucket with cold water and a sponge in it, and if the tube gets too hot you can then cool it a little. Frequently try the waist ribs in course of bending into the places already prepared for their reception. The others you may bend to fit the inside pattern.

*Gluing Ribs.*—Now make a "caul" or small block of wood (the 1 in. pine will do very well) to fit each of the hollows, and mark them to their places; then put them on a stove or near the fire to get hot; this causes the glue to set much sooner. Lay a coat of glue on one waist block, place the hot "caul" against it, and putting the end of an iron cramp into the hole exactly facing the hollow, cramp it close up, but see that both edges are a little "proud" of the model. You will not be able to glue both ends of each rib at one operation; let one end set before gluing the other, as the cramps might be in the way of each other.

When all the ends of waist ribs are fast, in proper positions, you should with a flat toothing plane cut the ribs down level with the model.

Now carve the remaining blocks in the same way as you did the waists, but you must cut through the end of each *waist rib* as well as the block to which it is attached, otherwise a nasty joint may result. Correctly file all the six blocks and make "cauls" to fit each, then mark them to their places. Glue and fix each of the corners, leaving top and bottom until the last. There is no necessity to make a joint with the ribs at the top, as both ends will be cut away when you fix the neck. If the bottom joint of ribs is not good, the defect

may be remedied by inserting a piece of purfling or fancy wood, but this must be exactly true to the centre mark. I have a weakness for putting in a narrow strip of ebony, and think it looks very well when finished: the bottom nut or rest crossing the top of this piece makes a "capital" T.

*Planing down Ribs.*—When the ribs are firmly set you should proceed to plane them down to the model, and finish them in the following way: set your compasses to $3\frac{3}{4}$ in., and from the point where the short line crosses the centre line of model, describe a circle, whose circumference gives the points at which the ribs should be square across. Fasten the model edgewise in the vice, and file each curve square across and free from inequalities, and make the entire set of ribs an equal thickness. After this has been nicely done, scrape them over, and give three or four courses of sand-paper, the last one very fine,

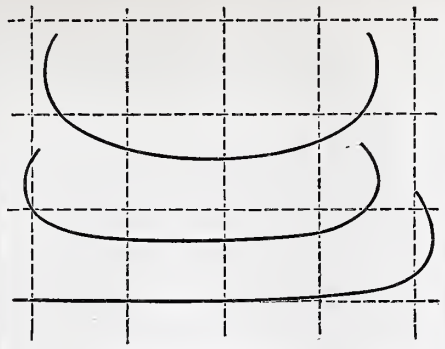

Fig. 6.—Stages of bending Waist Ribs (half size).

back, and trace around it with lead pencil; turn the pattern over, and complete the outline. Next place the model, back downwards, exactly true to centre joint, and an equal distance all round from the pencil outline already traced, and fasten it in that position with an iron cramp at each end. Now correctly trace on the back the outline of the ribs with a fine pointed marker, and then remove the model, and mark out the belly in the same way as the back; but as the "tab" or "button" on the latter will not be required on the belly, the outline must therefore be continued across the top.

*Sawing out Back and Belly.*—Your next business is to saw these two shapes out with the bow or a fret-saw, keeping just outside the pencil mark. With the compasses draw a line all round the upper or bevelled sides of both back and belly, $\frac{3}{8}$ of an inch from the edge. Now set your cutting gauge to $\frac{3}{16}$ in. and cut a strong line that distance from the flat side, all round both back and belly. With a dovetail or fine tenon-saw, and gouges, cut away the rectangular piece thus described, and afterwards level it with a flat oval plane (J, Fig. 5) and files, finishing it $\frac{5}{32}$ in. thick. The model, with the ribs on, should again be placed in the position marked from them on the back, cramped as before, and fixed in the vice, thus fastening securely the back and the ribs together. The edges should now be reduced with files

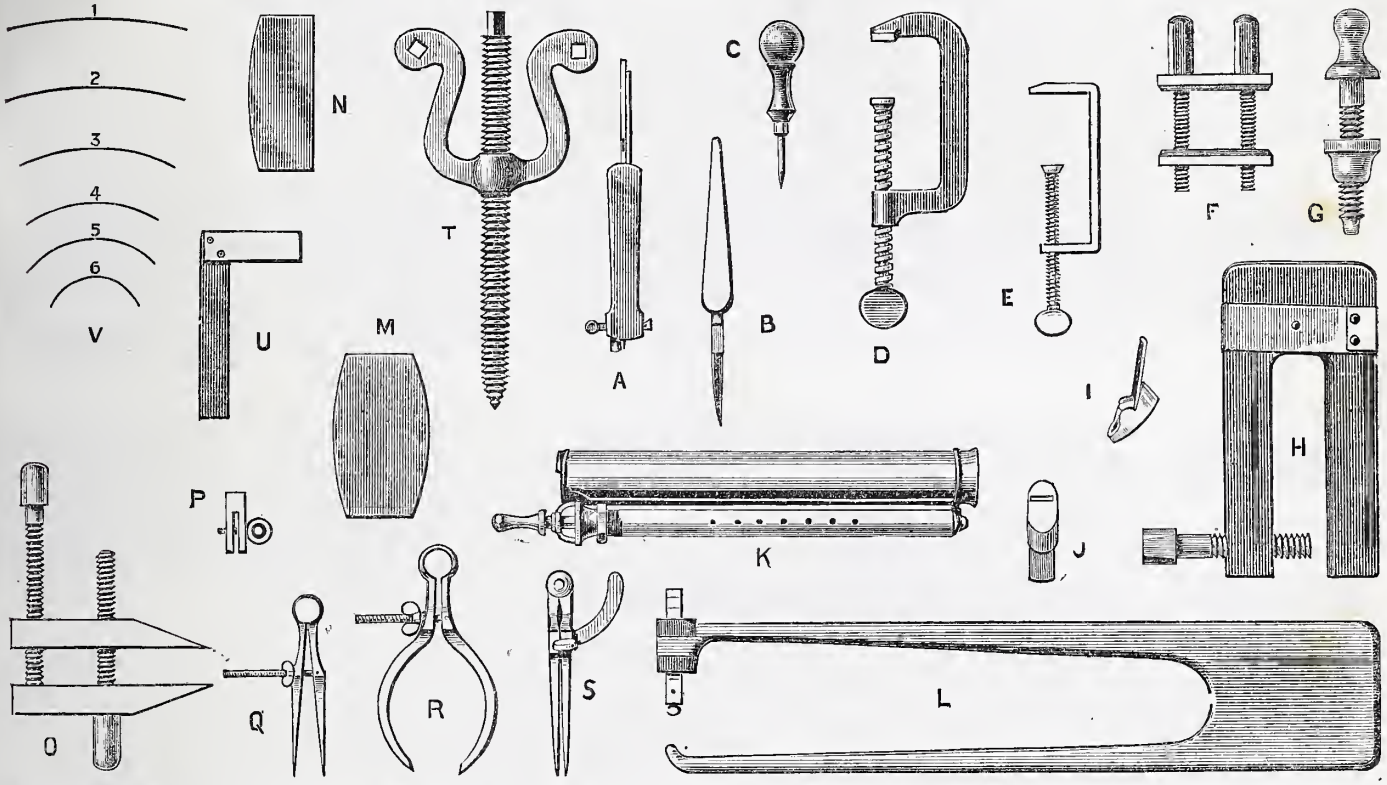

Fig. 5.—Some Special Tools used in Violin Making—A, Purfling Gauge or Cutter; B, Knife; C, Router; D, E, Iron Cramps; F, Cramp for fixing Back and Belly to Ribs; G, Cramp of Writer's Design; H, Wood Cramp; I, J, Small Iron Planes; K, Apparatus for bending Ribs; L, Thicknessing Gauge; M, N, Steel Scrapers; O, Hand Screws; P, Small Cramp; Q, Spring Dividers; R, Spring Callipers; S, Steel Compasses; T, Carver's Screw; U, Small Square; V, Sweeps or Curves of necessary Gouges.

and each one must be used on a cork rubber; work lengthways of the ribs, and preserve the edges absolutely square and sharp. Now square a light centre line down the bottom of the ribs, and midway of this line make a puncture which will show the position of end pin, the hole for which should then be bored with a $\frac{1}{4}$ in. bit.

*Marking Back and Belly from Ribs.*—The ribs are now ready, and the back and belly can be marked out from them, but first place (Fig. 2, p. 5) the outside pattern to the joint of the

until there is a perfectly even projection over the ribs of $\frac{1}{8}$th of an inch. Be particular to make the corners match in direction as shown in Fig. 7. Remove the model from the vice, and take the cramps off; now open the compasses to $\frac{7}{16}$ in., place one point on the joint of the tab $\frac{1}{8}$ in. from the rib line, and describe a semicircle: this gives the form the tab will bear, or nearly so. In Fig. 8 will be given a back with edge reduced and ready for purfling, of which operation I shall give an account in my next paper on violin making.

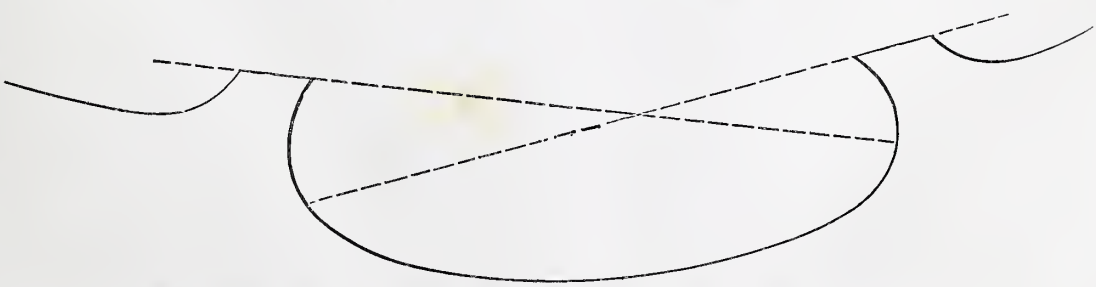

Fig. 7.—Diagram showing by Dotted Lines the Directions in which Corners should be cut.

# VENETIAN BLINDS.

BY B. A. BAXTER.

PROCEDURE—MATERIAL—METHOD OF CUTTING—CONTENTS OF A BUNDLE OF 100 FT. SUPER.—LONG LATHS CANNOT BE PLANED USING AN ORDINARY BENCH STOP, BUT BY TENSION, HELD BY HOOKS—HOLES ABOUT ONE-FIFTH FROM ENDS OF LATH—NUMBER OF TAPES MUST BE TWO OR MORE FOR OVER 4 FT.—LAP OF LATHS—TAPES OR LADDERS—HOW SET OUT—STUFF FOR HEADS AND THICK LATHS—ADJUSTABLE ANGLE—HOW SECURED—PULLEYS AND CORDS—ROLLERS AND WEBS—PAINTING AND VARNISHING.

THESE blinds, once so popular, and likely again to become so, are of very simple construction, though the opportunity of making mistakes is greater than in almost any other work with which I am acquainted. Like all other work where there is a constant recurrence of the same forms or the same operations, it is necessary to observe routine methods, and to divide the work up into as many separate portions as possible, each portion requiring but few tools, and each also being easily mastered. It is not necessary to give these varied operations to separate workers, though in shops where boys are employed, they, of course, do the simplest portions of the work; but it is necessary to divide the work up into parts, and do each part before another is begun, or confusion will result from the want of method.

The wood of which Venetian blinds are made is American pine—that variety which, when exposed to the air, takes a pinkish tinge being preferable; and it should be free of knots, shakes, sap, or resin—resin, that is, that looks as if a knife had been inserted into the wood, and the opening made thereby filled with a glutinous stopping.

The qualifications of pine for this work are its lightness, straightness of grain, and ease of working, and its standing the heat of the sun, which, behind glass, is often considerable.

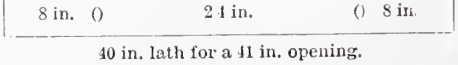
Pine, as most of our readers know, is usually in planks 11 in. by 3 in.; for blinds, however, the saw-mills proprietor is more concerned about quality than dimensions—smaller timber will do, if good. Supposing, however, the stuff is 11 in. by 3 in., it is first reduced to 2½ in. (this is the usual width for blind laths, for reasons which will be explained presently); then it is cut down the centre, and then cut after cut is made, so as to remove pieces 2½ in. wide and ⅛ in. thick. This is the ordinary thickness, and the saw used is a circular saw, ground so that it is thin at the edge; the teeth are small and the set slight, so as to leave the wood as smooth as possible, and not to make deep furrows, to need much planing out. A thin saw wastes less wood than a thick one, which is an additional reason for its adoption.

The laths thus cut are sold in bundles of 100 ft. superficial, or 480 ft. run, which is the same; 12 ft. long and 2½ in. wide being equal to 2½ ft. superficial; forty of such pieces, therefore, are equal to 100 ft. superficial.

The saw-mills people now usually also sell the laths planed and the edges rounded. This formerly, and not so long ago, added 3s. 6d. to the cost per 100 ft.; competition and machinery have reduced this of late years, but the laths are still advertised as "hand-planed"; and sometimes they are.

When planed in long lengths, blind laths are too thin to resist the strain of planing, so they are held by two or three brads or wire nails driven into the rear end of the bench nearly as far as the heads, which are cut off, and the remainder filed to the necessary shape. The laths pressed down on these hooks will hold well enough for a finely-set plane to work well upon them. The edges are rounded with a plane made for the purpose, but failing the special tool, an ordinary ¼ bead plane will do well.

If the laths are bought unplaned, the workman may plane them first, as above, or he may cut the laths to the appropriate lengths and then plane them; it is scarcely needful to remark that in that case the filed hooks are not used. It is optional to round the edges before or after the flats are planed, but very often the laths are cut to the proper lengths, then the edges planed with a jack-plane in groups of about twenty-five at a time in a trough made for the purpose; then the flat surfaces planed and the edges rounded. The holes for the passage of the cord used to be made with a gouge, preferably one ground inside; but for those who mean to make any considerable number of blinds, a punching press, of which many suitable patterns are made, is a necessary investment. When the gouge is used, a bradawl is put through the laths at the proper distance from each end, thereby holding the group of about six laths in position while they are being sawn, as well as marking the place for the hole. In deciding the place for cutting these cord holes, it may help to advise the usual allowance of ½ in. for freedom of the lath at each end, and one-fifth of the length of the lath for the distance of the holes from each end: thus—



40 in. lath for a 41 in. opening.

It is customary to have three tapes, and consequently three holes and cords, to all blinds over 4 ft. wide; and Venetian blinds for shop windows may well have four, or even more, tapes and cords, according to their size.

As a Venetian blind must be fixed together in such a way that it can be drawn up, and so that the laths lap or cover each other, laths 2½ in. wide are usually placed 2 in. apart—six to the foot. Tapes or webs, with cross-pieces sewn at intervals, are needed.

These tapes, or ladders, as they are sometimes called, are made of a webbing intended for the purpose; and before Carr's patent woven web appeared in the market, the making of the tapes was the great difficulty in the way of beginner or amateur, but now the patent woven ladder webs make blind making possible to anyone who can use wood-working tools and a paint-brush.

To those who wish to know how the blind makers of a former time managed, I may say that the tapes were tacked temporarily on a board, to the edge of which a strip of wood was affixed. This strip we divided carefully with compasses into parts 2 in. between the lines, and other distances on other sides of the strip, or on other strips which did duty upon occasion when other distances were needed. Having the tapes on the board, and the divided strip visible on its further edge, the operator transferred the marks with a T-square and pencil; only a little care to stretch the web equally tight was needed to ensure a satisfactory result. It is evident that the worker could allow the proper distance for the lowest and thicker lath by this way of marking the tapes, in which respect only the old way was superior; but the woven web may be recommended to all amateurs and beginners, notwithstanding that the folding of the cut ends of the web are a slight difficulty.

The narrow tapes, about ⅜ in. wide, are usually set out by winding the material round a piece of wood 2½ in. wide and ¾ in. thick; this may be of any convenient length, and when the tape is neatly wound, red chalk or black lead is slightly rubbed along each corner or arris of the covered strip of wood. A sharp knife or chisel is then used to cut along the centre of the ¾ in. edge of the wood, thus dividing each strap from its neighbour, and leaving each with marks indicating the place to sew on to the wider web.

I mentioned the lowest and thicker lath just now: anyone who has seen a Venetian blind knows that it contains thin laths,

Fig. 4.—Section through both Pulley and Roller, showing Position of Cord (B) and Spacing Block (A), and Cord (C) to alter Angle of Lath. Fig. 5.—Right-Hand End of Lath, showing Relative Positions and Sizes of Mortises—B, Centre Line of Cord; X, Front; Y, Back.

varying in number according to its length, and two stouter laths, one at the bottom and one at the top, to which the tapes are affixed, the whole being suspended to the head or pulley lath, as it is variously termed; 4 cut stuff is about right for these thicker laths, and 1 in. or 2 cut for the head or pulley lath. "4 cut stuff" is a technical term. It means that the plank has four cuts in it, thus making five boards about $\frac{5}{8}$ in. thick.

In order to give adjustment of angle to every lath in the blind, there are rollers let into the pulley lath, the axes of which are parallel to the edge of the lath. The movable laths rest in the tapes affixed to the stout lath at the top, which is fixed to the pulley lath by webs passing over the aforesaid rollers, and parallelism of the whole (which is important) is secured by using a spacing block, or a pair, between thick lath and pulley lath, while the web is drawn over roller and lath and tacked in its place.

Before we proceed to paint our thin laths, we must take off with some glass-paper the fibre or rough edge left at the ends of the laths by the saw. This is usually done a number at a time, and the group of thin laths can be held in various ways so as to secure contact with the glass-paper on each edge of the ends in turn.

The probable reason why $2\frac{1}{2}$ in. has been universally chosen as the ordinary width for Venetian blind laths is because that is the widest that could go between the beads in $1\frac{1}{2}$ in. sashes, and that width of lath has become universal, because variations in width would be inconvenient.

The blinds are drawn up by cords passing over pulleys; the axes of the pulleys are at right angles to those of the rollers just mentioned, and by a simple method the cords are made to draw up—in most cases at the right-hand of the window—while the cord that slopes the laths at pleasure is usually at the left hand.

In the diagrams that accompany this description this will be seen, and the arrangement of pulleys and rollers made clear.

The pulley laths serve the double purpose of fixing the blind, and also form the place of attachment for the pulleys and rollers. Reference to Fig. 1 will show how these pulleys are arranged so as to escape contact with the sash beads. The outer beads are usually $\frac{5}{8}$ in. by $\frac{3}{4}$ in., therefore the foremost of the two pulleys should be quite that distance from the front. The pulleys are made of various sizes, but 1 in. diameter is the most useful size for all but the smallest blinds. The mortises for the pulleys are generally cut with a $\frac{3}{4}$ in. chisel.

The rollers are seen in Figs. 2, 3, and 4, and are cut with a $\frac{5}{8}$ in. or $\frac{3}{4}$ in. chisel; the length is abont $1\frac{3}{4}$ in. The lower side of these mortises must be enlarged, as shown in Figs. 3 and 4, because the web which passes over the roller also passes over the lath, which is $2\frac{1}{2}$ in. wide.

The figures also show how the pulleys and rollers are centred, the latter needing the wire to be let into a mortise cut for its reception. This is shown in Fig. 4. The holes for screws for fixing must not be forgotten, as it is most inconvenient to find no screw-holes when you have the blind put together and are about to fix it. Figs. 2 and 5 show suitable places for screws.

The stout laths which form the top and bottom laths, and to which the tapes are secured, have cord-holes corresponding to those in the thin laths, but those in the top are larger than those in the bottom, which are small enough to retain the knot in the cord, neatly covered by the tape, and resting in a countersink made in the bottom of the bottom lath.

We have now our blinds cut to size, and the cord-holes cut or punched; they are, of course, planed, rounded, and the edges of the ends and corners rubbed with glass-paper. We will now paint or varnish them.

In painting blinds we must guard against the use of too much oil; no boiled oil must be used at all, on any account, and the first coat of colour the laths receive is very frequently composed of size and whiting. This should have no water added to the size, which should not, in melting, be allowed to boil. When well melted, the whiting should be crushed and stirred in gradually; and not a great deal is needed, or the mixture will be too thick to put on easily, and will dry with coarse brush-marks. The painting of blind laths needs a quick and light touch, or some of the laths will be broken. A 000 or 0000 brush is suitable—oval brushes are preferred by many—and the lath, while being painted, is held by the left first finger and thumb at the hole in the lath, the other end resting on the board fixed on the painting bench. The paint which follows the size colour may be ordinary *raw* oil colour, rather sharp, and still more turps for the finishing coat.

For varnishing, two coats of patent size of best quality—vellum size for choice—the first coat of which may have some water added, and the second some, but less. The varnish may be best church oak, and blinds should have two coats of varnish, pure as received from the maker.

The arrangements for drying the laths differ, but the general plan is to fix a piece of quartering, in which is driven pieces of the stoutest iron wire (about $\frac{1}{4}$ in. diameter), about 15 in. or 16 in. long and about $4\frac{1}{2}$ in. apart. Each of these will hold about ten laths, and the whole arrangement of quartering and wires is fixed on the wall horizontally, and higher than the eyes of the workmen.

I need say nothing about the putting together and fixing, because anyone who can do the preceding work can easily overcome the remaining difficulties, but one word of warning must be uttered: do not, in putting in the cords, allow the cord to depart from its true course, which is down the centre of the wide tapes, and therefore alternately to the right and left of the short tapes on which the laths rest. If you make any mistake, rectify it at once; do not treat it as a matter of indifference, for a cord inserted in the wrong way will do mischief to itself and the tapes until it is put right.

Lastly, as the parallel position and equal spacing of the thin laths depend on the accuracy of the tapes, so the spacing and parallelism of the lowest lath depend on the care with which it is tacked in its place. The absence of attention to this trifle makes a great difference in the appearance of the finished work.

After a trial or two the making and finishing a Venetian blind will not be found so difficult as it may seem at first sight. It will be good practice for anyone who has in his possession, or can become possessed of, an old blind to take it to pieces and put it together again. From this point of view it follows as a matter of course that any paper will prove useful to those who merely wish to clean the blinds or even to furnish them with new tapes. In taking a blind to pieces for the first time, due regard should be paid to the construction and arrangement of the cords.

## HOW TO MAKE A QUARTER HORSE-POWER STEAM ENGINE.

BY F. A. M.

### Theory and Action of the Slide-Valve.

Engines not made Self-Acting at First—The Plain Slide-Valve without Lap—Slide-Valve with Lap for Expansive Working—Stroke of the Eccentric—Lead of the Valve—Angle of Advance, of Admission, of Expansion and Release, of Exhaust and Compression — Inside Lap — Use of Lead—Lineal Admission and Expansion in Parts of the Stroke—How to Arrange for more Expansive Working—High Rate of no use in Unjacketed Cylinders — List of Castings and Tools required for making the Engine.

*The Slide-Valve.*—It would be quite possible to put together the engine we have in hand without any directions beyond those which accompany the drawings; but no amateur engine-maker will be content to be ignorant of the action of so vital a part of the machine as the slide-valve, nor of so beautiful and ingenious an adaptation of means to an end—a problem which may well be considered as a kind of *pons asinorum* in steam engineering. Besides, if we do not master the slide-valve, we cannot certainly go on to deal with link motion or expansion gear.

It may not be generally known that the first steam engines required a man, or boy, constantly beside them, to turn on and off at every stroke the cocks which directed the steam into and out of the cylinder. We can hardly imagine such a state of things in these days; but it continued until a boy, who wished to exchange work for play, had ingenuity enough to connect by strings the handles of the cocks with some of the moving parts of the engine, in such a way that the engine did for him the work he was set to do—a real invention, for he had made the steam engine *self-acting*.

The distribution of steam in the modern engine is controlled by the eccentric and slide-valve — a beautiful and smoothly working arrangement, almost perfect in its action. The eccentric is keyed upon the shaft and gives motion to the slide-valve, so that, no matter what may be the position of the piston in the cylinder, the slide-valve will always be, of necessity, in the correctly corresponding position. The steam is led from the boiler into a steam-chest, or valve-box, upon the side of the cylinder, and the duty of the valve is to direct the steam upon the back of the piston to drive it up the cylinder for three-quarters of the stroke; then to stop the supply till the piston reaches the end, and then to bring the steam upon the front face of the piston to drive it back, whilst it allows the first cylinderful of steam to escape by the exhaust pipe.

Looking at Fig. 1, the valve v and the ports or steam-ways P, P,' will be seen in section, leading the one to the top and the other to the bottom of the cylinder (called top and bottom merely for convenience of description). There is a third port between the other two called the exhaust port, E, which is *always covered* by the slide-valve, and through this the steam makes its escape; the pressure under the valve, therefore, will be the same as that in the exhaust pipe which opens into the air, whilst the pressure upon the outside of the valve is 50 lb. per square inch, or whatever may be the pressure in the steam pipe which supplies steam to the box in which the slide-valve works. The valve fits so perfectly upon the face that only the merest whiff of steam—a hardly

perceptible quantity—can pass between the surfaces, and the same is true of the fit of the piston in the cylinder. All that escapes in either of these places is loss, and, if well and carefully fitted, there need be no loss. The difference of the pressure outside and inside the valve causes it to be held up firmly against the valve-face on the side of the cylinder. The figure also shows the eccentric which moves the valve, but this is drawn as if it were turned a quarter round, so as to show its flat side instead of its edge.

We may now pass on to Fig. 2 and investigate the action of the plain slide-valve without lap. At Fig. 2*a* will be seen the valve which belongs to Fig. 2. Lay a piece of tracing paper over Fig. 2*a*, and trace the valve with the base line to *h*, and the verticals *g*, *h*, and *k*. Lay this tracing on Fig. 2 and see that these vertical lines correspond with those of the figure beneath, whilst the edges of the valves *a b*, *c d*, coincide with the edges of the ports A B, C D; thus the valve will be in the middle of its course, whilst the point *g* on the tracing will coincide with *z*, the centre of the circle representing the movement of the eccentric. Evidently the ports are all closed and no steam can pass anywhere; the piston then must be at one end of its course. Let us place the crank upon the line *z r*, and suppose the piston to be at the top end of the cylinder. Looking at the valve, we see that whether the crank moves upwards or downwards from *r*, the valve must move to the left so as to uncover port P to the steam and port P′ to the exhaust; if then the crank is to go round *upwards* from *r*, the eccentric must be fixed at *s*, but if the crank is to go *downwards*, and go round as a watch does (forwards), then the eccentric must be placed at *t* to make the valve move to the left. *Fix the eccentric at t, and the engine will run forwards; fix it at s, and it will run backwards.*

Thus we arrive at this conclusion: that when the edges *a b*, *c d*, of the valve are the same width as the ports, the eccentric must be keyed at an angle of 90 degrees *in front* of the crank.

Let us now suppose we determine that the engine shall go forwards and the crank go downwards from *r*. Suppose it to move one-quarter round from *r z* to *y z*, then the eccentric will have moved from *t* to *v*, and the valve will move to the left while the eccentric passes round the quarter circle till the point *g* coincides with *v*, *d* with C, and *b* with A. The piston is now in the middle of its course, moving at its greatest velocity, and the valve has been opening both steam and exhaust openings wider and wider till they are now opened to their widest extent. Continuing the movement through another quarter circle, the crank continues its course till it arrives at R *z*, bringing the piston to the bottom end of the cylinder, whilst as the eccentric passes over the arc *v s*, the valve returns again to its former central position, gradually closing the steam and exhaust openings as the piston comes gradually to rest. Now, however, though the valve is in its first position, the crank is at R and the eccentric at *s*, and therefore the further movement of the crank and eccentric will cause the valve to move to the right of its central position, opening port P′ to the steam and port P to the exhaust, so that now the direction of the steam is reversed, it flows into the back end of the cylinder, and the steam which did the work during the last stroke escapes under the valve to the exhaust.

Fig. 2, with the tracing of Fig. 2*a*, will enable the student to find the corresponding position of the valve for any position of the crank. It simplifies the problem by getting rid of the eccentric rod, the angularity of which is so slight that the error thus introduced is unapprcciable.

Having now studied what may be called the rudimentary slide-valve, which would only be suitable for a water engine, we will proceed to show how by altering its dimensions its working may be greatly improved.

A great fault in the arrangement of the valve of Fig. 2 is that it does not allow the steam to be used expansively. Without going deeply into the subject, it must be evident that, with the valve just considered, the steam will continue to enter the cylinder and drive forward the piston to the very end of its stroke, and that then the exhaust valve will allow the whole cylinderful of high pressure steam to escape, though it has in it power enough to do a great deal more work. Suppose, instead of this, we had arrested the flow of steam into the cylinder when the piston had only travelled through half its stroke, the half cylinderful of steam, say at 40 lb. pressure per square inch, would have begun to expand, and would have continued to press forward the piston until it arrived at the end of its stroke, when, having doubled its volume, its pressure would have fallen to one-half (reckoning from vacuum) what it was at first. By this means half as much steam would have been made to do almost as much work as the whole cylinderful.

There are, however, practical reasons why it is not well to carry the system of expansion very far in a small unjacketed cylinder like the one we have before us, and the limit has been fixed at three-quarters—that is, the proportions of the slide-valve have been arranged in such a way that when the piston shall have travelled over three-quarters of its stroke, the ingress of more steam shall cease, and the remainder of the stroke be completed whilst that steam expands. The arrangement saves at every stroke one quarter of a cylinderful of steam, and the average pressure is reduced about 2 lb., whilst the terminal pressure falls to three-quarters of the initial. How this is done can be seen by referring to Fig. 3, which, with its valve, represents the arrangement and proportions actually adopted. The letters of reference are the same as in the former example, and the tracing of the valve, Fig. 3*a*, should be made as before. Laying this second valve tracing on Fig. 3 in its middle position, we notice that whilst the points *b* and *c* on the valve coincide as before with edges B and C of the ports, edges *a* and *d* of the valve *overlap* the port opening by a distance D *d*, A *a*, equal to the width of the port opening; this distance of overlap is an important dimension, and it is called *the lap* of the valve; in this case we should say we have one port of lap.

Let it be noticed that the valve is not, when in its middle position, properly placed to begin to admit steam through port P so that the piston may begin its "in" stroke; it will not do this till the valve has moved to the left, until edge *d* reaches edge D. Moreover, it will not have opened the port fully till edge *d* reaches edge C. Supposing we wish to arrange the valve to open this port fully, we must make the radius of the circle of the eccentric equal to the distance *c* to *d*, or *a* to *b*; and since in our case we have made the ports $\frac{1}{4}$ in. wide, this radius will be $\frac{1}{2}$ in., and the eccentric will have an eccentricity of $\frac{1}{2}$ in., and the stroke of the eccentric and valve will be 1 in., which is the way the size of the eccentric circle on Fig. 3 was determined. To find the proper angular position for the centre of the eccentric upon this circle, move the valve to the left till edge *d* has just passed edge D by the thickness of a visiting-card, say $\frac{1}{64}$ in.; this distance is called *the lead* of the valve. Now observe where the line *g h* on the tracing cuts the eccentric circle at *t*, join *t z*, and produce the line to *s*; *t* is the position the centre of the eccentric must occupy when the crank is at *r* ready to begin the "in" stroke, and the angle *r z t* is called *the angle of advance*. It is the angular distance by which the eccentric precedes the crank; in this case, were it not for the slight addition made to it by the lead, this angle would be 120 degrees. We may now, by the help of our diagram, watch the action of the valve, and determine at what points in the revolution of the eccentric the inlet and outlet of the steam occurs. Beginning at *t*, the valve edge *d* having just passed D let the eccentric move on to *v*, and *d* to C; here the valve is fully open; pass on from *v* to *p* (determined by the edge *d* reaching D), and the valve closes and stops the admission of more steam; *t z p* is *the angle of admission*. By dropping from *p* the perpendicular *p p′* upon the diameter *t s*, we find that if the distance *t s* represents the length of the stroke, then distance *t p′* represents that part of it during which steam is admitted. Let the eccentric continue its course from *p* to *o*, and the valve will reach its middle position; but here another event occurs. Edge *c* of the valve passes edge C of port P, which opens it to the exhaust; the steam that was expanding in the cylinder will therefore escape when the eccentric reaches the angular position *o*, and the piston the position corresponding to *o′*, whilst the stroke does not end till the point *s* is reached at 180 degrees from *t*; angle *p z o* then is *the angle of expansion*, angle *o z s the angle of release*; if *t s* represent the length of the stroke, then *t p′* is the admission, *p′ o′* the expansion, and *o′ s* the release. Following the eccentric round from *s* through *w* to *n*, we note that at *s* the piston begins its return stroke, which ends when the eccentric reaches *t*; but that, just as the exhaust begins at angle of *o z s* before the completion of the stroke, so in like manner the exhaust ends at *n* before the exhaust steam has been completely expelled. Dropping a perpendicular from *n* to *n′*, we find that if *t s* represent the length of the stroke of the piston, then, when it shall have returned from *s* to *n′*, the port P will be closed to the exhaust, and during its remaining course from *n′* to *t* it will *compress* the exhaust steam remaining in the cylinder, which will have the effect of raising its pressure; so that when, just before the next stroke begins, the port P opens to the steam again, this high pressure steam will not have to fill a port-way and cylinder-end at atmospheric pressure, but will find there already a pressure of some 15 or 20 lb. The angle *n z t* then is called *the angle of compression*; it is a decided advantage to the engine. Moreover, the angles of release and of compression can be varied: we can take from one and add it to the other by simply adding to or reducing the distance *b* to *c*. Suppose a little piece *m* (Fig. 3*a*) to be fitted inside the valve, and watch its effect; it will move the points *o* and *n* on the eccentric circle a little further to the right; it will take a little from the release and add it to the expansion, and,

by the same amount, it will increase the compression. Such a piece added as at *m* would be called *inside lap*; it is sometimes used, but the more usual practice is to make *b c* equal to B C.

The use of the lead is to take up the looseness of the joints of the connecting-rod ends, and so to prevent any knock on the dead points. It will be understood that as the force of the steam urges the piston first in one direction and then in another, if there were the slightest amount of play anywhere in the joints, between the piston and crank, the pins would be forced first to one side and then to the other of each joint, causing a disagreeable thump at the beginning of each new stroke, at the moment the steam came on to the piston. By means of the lap, and also with the help of the compression, the motion of the piston is retarded at the end of each stroke, so that the momentum of the fly-wheel takes up all looseness in the joints, in such a way that the pressure of the fresh steam is transmitted solidly to the crank-pin. When this is properly done in every respect, not the slightest knock or thump will be heard as the engine piston reverses its movement in the cylinder.

If it be required to find at what parts of the stroke in inches the various incidents take place, the eccentric circle in Fig. 3 can be surrounded by another circle, as seen dotted in the figure, having a radius equal to that of the crank—$2\frac{1}{8}$ in.—and the various angles of the eccentric positions can be produced to the circumference of the larger circle, and perpendiculars let fall upon its diameter; these perpendiculars will now mark off the different parts of the stroke in inches. By this method it was found that, the stroke being $4\frac{1}{4}$ in., the admission occupied $3\frac{3}{16}$ in., the expansion $\frac{3}{4}$ in., and the release $\frac{5}{16}$ in.

It may now be said, that as the ports are, of necessity, made large enough to give free exit to the exhaust steam at atmospheric pressure, it is not necessary that they should be fully opened to admit the high-pressed steam; we can, therefore, if we like, employ an eccentric with only $\frac{3}{8}$ in. eccentricity. We shall leave it to our readers to work out the full results of this change, only stating that the angle of advance will be increased by about 8 degrees. The cut off will occur soon after the half stroke has been passed, and the ports will never open more than $\frac{1}{8}$ in.—one-half their width. The arrangement would be a good one; it would use less steam and give out but little less power than the one already examined. Economy in so small an engine is not of much consequence. Possibly it might amount to a saving of a penny a day, and readers might do well to adopt it if they can afford to sacrifice a little power, or if their boiler is deficient in steaming capacity. An expansion of one-half is about the limit of what can be obtained by the single slide-valve. Even with that amount the release and the compression grow to rather formidable proportions. If we wished to work still more expansively, we should have to employ a second eccentric to work a second slide-valve, moving upon the back of the first, and by this means the expansion might be carried to any degree desired. It is, however, no advantage to use a high degree of expansion in a cylinder not provided with a steam jacket; and the very small amount we might hope to save in so small an engine does not make it worth while to incur so much extra expense and complication.

*List of Castings supplied, and of Tools required, for making the $\frac{1}{4}$ H.P. Engine.*

In buying castings, the present writer has found some difficulty in dealing with those who are only known to him by their advertisements. Many of these are strictly honest, but it is not so easy to know how best to deal when prepayment is demanded. Some advertisers, partly through carelessness, are apt to delay a long while before attending to an order; and, when at last the goods arrive, there is some essential part missing. If one is liable to such annoyances in England, how much more so in the Colonies! It is with a view of preventing such annoyance to those readers of these papers who might wish to obtain a set of castings, that a set of excellent patterns have been made. From these, as soon as it is practicable, castings will be made by a man on whom some of us think we can depend. So that it is hoped that the owners of the patterns will soon be in a position to execute orders for them from all parts of the United Kingdom, the Colonies, or anywhere else, and to forward the cast-

ings complete, without unreasonable delay. Of this, however, due notice will be given by advertisement in Work.

Another great annoyance to a would-be engine builder is to find himself suddenly pulled up by the want of some little forging it was supposed he would be able to make, or of a bit of brass rod to make some small part for which no casting has been supplied. To avoid this, castings are provided of many very small parts which might have been made of a bit of brass rod, if the workman happened to have a suitable piece, but, for want of which, he might have had to wait. Our readers' patience will be sufficiently tried if they undertake this piece of work without any disappointment of such a kind, and an attempt has been made to save them all unnecessary trouble.

The first list, here following, is that of all castings and materials required to *make the engine alone*, without either pump or governor.

List of Castings and Materials for Making Engine Alone, without Pump or Governor.

| *No. of Pattern.* | *Description of Casting.* | *No. of Castings.* |
|---|---|---|
| 1 | Bedplate | 1 |
| 2 | Cylinder | 1 |
| 3 | Top Cover | 1 |
| 5 | Bottom Cover | 1 |
| 6 | Piston | 1 |
| 7 | Piston Bottom | 1 |
| 10 | Steam Chest | 1 |
| 12 | Steam Chest Cover | 1 |
| 15 | Crosshead | 1 |
| 17 | Fly-wheel | 1 |
| 18 | Crosshead Guides | 2 |
| 28 | Angle Bearings | 2 |
| 29 | Caps for do. | 2 |
| 34 | Eccentric | 1 |
| 35 | Ecc. Half Strap (rod end) | 1 |
| 36 | do. do. do. (outer end) | 1 |

All the above in Cast Iron.

| | | |
|---|---|---|
| 4 | Gland for Cylinder Cover | 1 |
| 8 | Piston Rings | 1 |
| 9 | Piston-rod Nut | 1 |
| 11 | Gland for Steam Chest | 1 |
| 13 | Slide-valve | 1 |
| 14 | Valve-rod Nuts | 4 |
| 30 | Bearing Brass (bottom) | 2 |
| 31 | do. do. (top) | 2 |
| 32 | Con.-rod Brasses (small) | 4 |
| 33 | do. do. (large) | 2 |

All the above in Gun Metal.

| | | |
|---|---|---|
| 16 | Connecting-rod | 1 |
| 38 | Valve-rod | 1 |
| 39 | Eccentric-rod | 1 |

These three in Malleable Cast Iron.

1 Crank Shaft in Wrought Iron.

With the above, 5 Stauffer lubricators, smallest size; one ½ in. brass screw stop valve with nipples to fit.

Castings Required for Feed Pump.

| *No. of Pattern.* | *Description of Casting.* | *No. of Castings.* |
|---|---|---|
| 19 | Pump Body | 1 |
| 20 | Pump Cover | 1 |
| 21 | do. Gland | 1 |
| 22 | do. Union Nut | 1 |
| 23 | ¼ in. Spindle-valve | 1 |
| 24 | $\frac{5}{16}$ in. do. do. | 1 |
| 25 | Pump Plunger | 1 |
| 26 | Liner for do. | 1 |

All the above in Gun Metal.

| | | |
|---|---|---|
| 27 | Pump Eccentric Rod | 1 |

Of Malleable Cast Iron.

| | | |
|---|---|---|
| 35 | Half Strap of Eccentric for Pump | 1 |
| 36 | Other half of do. for do. | 1 |
| 37 | Pump Eccentric | 1 |

Of Cast Iron.

Castings, etc., Required for Governor.

| | | |
|---|---|---|
| 40 | Governor Bracket | 1 |
| 43 | do. Balls | 2 |

Of Cast Iron.

| | | |
|---|---|---|
| 41 | Governor Sleeve or Body | 1 |
| 42 | Do. Pivot Pin | 1 |
| 44 | Driving Pulley | 1 |
| 45 | Throttle-Valve | 1 |
| 46 | Do. do. Case | 1 |
| 47 | Do. do. do. Gland | 1 |

Of Gun Metal.

Other Materials: Four inches of ¼ in. steel tube $\frac{3}{8}$ in. bore. One pair of 1 in. brass mitre wheels.

Tools Required to Make the ¼ H.P. Engine.

1. A metal turning lathe, with slide-rest, is necessary; if the fly-wheel is to be bored, it must have a gap capable of taking in a diameter of 16 in. If it is not a self-acting lathe the cylinder had better be ordered ready bored. The lathe should not be less than 5 in., or at least 4½ in., centres.
2. A universal chuck three or four inches in diameter is desirable.
3. A face-plate chuck 8 in. to 10 in. diameter is necessary. It must have dogs and bolts.
4. An angle-plate chuck to bolt on the face-plate.
5. A vice. A 10s. 6d. parallel vice might do, but a larger one would be better.
6. A set of flat and round files and some cold chisels.
7. Screwing tackle, a screw plate and taps up to ½ in. or $\frac{7}{16}$ in., a stock, and dies for brass gas-threads.
8. A set of straight flute or Morse twist drills up to ⅜ in. with drill chuck.
9. A drill gauge is very useful; it costs 12s. 6d. from Churchill's, and contains a number of holes from $\frac{1}{16}$ in., up to ⅜ in. rising by $\frac{1}{64}$ in.
10. A surface-plate and scribing block.
11. Squares and callipers.

## OUR GUIDE TO GOOD THINGS.

*** *Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of* Work *for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of* Work *without charge, the notices given partake in no way of the nature of advertisements.*

### 9.—Black's Patent Fastener.

Mr. Alexander Black, High Street, Cowdenbeath, N.B., has produced a new kind of fastener for shirt studs, a specimen of which he has sent for inspection, and which seems likely to be useful to those who wear shirt-studs, solitaires, etc., as the patent fastener enables the wearer to insert and remove them with the greatest ease, and absolutely without injury to the linen. The fastener can be fitted to any size or form of stud; and Mr. Black claims for his invention that it is more secure when inserted than any other, and forms, with the top, one piece only; thus overcoming a difficulty never successfully met hitherto. In Fig. 1 is shown a representation of the stud when about to be inserted in the hole or holes made for its reception; Fig. 2 shows a side or sectional view of the appliance. It is used by inserting the ribbed end A of the fastener under one lip of the button-hole (as in Fig. 1), and then pushing it first to the right as far as it will go, and then to the left under the other lip of the hole, or in other words, to the left in order to bring B under the other lip. When it is desired to remove the stud, the movement is simply reversed. The spring clips the linen firmly in inserting and removing, and closes or locks when the stud is in position. There is no wear to the linen from the stud revolving in the hole. The neck being flat, it cannot turn, and always lies in position to be readily removed. The more stiffly starched the linen is, the better the working of the stud.

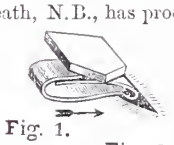

Fig. 1.

Fig. 2.

Fig. 1.—Black's Fastener. Fig. 2.—Ditto, side view.

### 10.—"The Art of Graining and Imitating Woods."

I have received from Mr. W. G. Sutherland, the managing director of the Decorative Art Journals Company, Limited, Parts 1, 2, and 3 of a superb work entitled, "The Art of Graining and Imitating Woods." Mr. Sutherland's name is so well known in the decorative world in connection with that kind of art-work of which he is so able a master and exponent, that it is enough for me to say that anything he produces is well worthy the attention of all professional painters and decorators who desire to attain excellence in their craft, and of all amateurs who are interested in the subject, and who wish not only to try their hand themselves at the imitation of woods by brush-comb and the requisite pigments, but also to possess safe and sure guidance in the art and the means of discriminating between good and bad imitations of the original woods, both in colour and veinings. I am sorry that I am unable to state at the present moment the price of the parts of this magnificent contribution to the literature of decoration, but I can put my readers on the right track for learning this for themselves by saying that the Company's address is 15, St. Ann Street, Manchester, and that Mr. Sutherland will undoubtedly be pleased to answer any inquiries. Further, the London publisher is Mr. Henry Vickers, 12, Catherine Street, Strand, W.C., where anyone resident in the metropolis and its vicinity might see the work, if he was so minded. To give those who cannot do so some idea of it, I may say that the size of the page is 18½ in. by 13½ in., and that there are eight of these large pages in each part, and four examples of the graining of different kinds of wood, beautifully and artistically rendered in colour, and representing the work as it should look when brought to completion. A chapter is devoted to the treatment of each kind of wood, and the letterpress is enriched with characteristic initial letters and tail-pieces, and in some cases with illustrations of the appliances used, of the modes by which some of the desired effects must be produced, and of examples of veining in black and white when it is helpful to show the peculiarities of the natural wood otherwise than by colour. To give some idea of the method of treatment adopted for the text, I will take Chapter VIII., on bastard mahogany or baywood—the kind of mahogany that is brought from Honduras, in Central America. In this we have first some mention of the history of the wood, especially as regards its use in this country and its rise and declension in popular favour. Then we are told in separate sections, each under its own heading, the "colours required;" the "grounding," how it is to be made; and "how to grain it," describing clearly the manipulation that is necessary. We are then introduced to "another method" of arriving at a similar result by "flogging in the ground," "pencilling," and "glazing." The value of the directions is further enhanced by side-notes in small type, which enable readers or those who use the book as a work of reference to gather the nature of the text without wading through it from beginning to end, by merely running the eye down the side of the column until the position of the information required has been found and noted.

### 11.—"Photography in a Nutshell."

Not long ago I called attention to a manual of photography entitled "Photography in a Nutshell," which was sent by the publishers, Messrs. Iliffe & Son, 3, St. Bride Street, London, E.C. It was in a paper wrapper, and its price was 1s. I have now received another copy from Mr. William Tylar, 57, High Street, Aston, Birmingham, which I am bound to notice on account of its marked peculiarity in having every right-hand page blank for notes. Mr. Tylar says: "I have much pleasure in sending for review *my* latest edition of 'Photography in a Nutshell.' I am sure that practical workers will welcome the combination of a practical book of reference with a note-book, especially as the interleaf is so arranged that the printed index refers to the written notes as well as to the corresponding printed paragraphs. It is an entirely new departure in photo literature." That it indeed is, and a departure that might be adopted with advantage in other books—especially books for use in schools and colleges. The new edition is bound in cloth, and its price is 2s. 6d. Whether or not Mr. Tylar is the "Kernel," the *nom de plume* of the writer of the volume, is a matter for speculation into which I do not attempt to enter, but with this, the entire absence of title page from the copy in my hands—another new departure in literature generally—has probably something to do.

The Editor.

## SHOP:

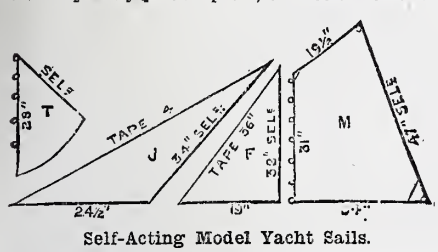
### A Corner for Those who Want to Talk It.

*** *In consequence of the great pressure upon the "Shop" columns of* Work, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* Work *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### I.—Letters from Correspondents.

**Self-Acting Model Yacht.**—T. H. C. writes:—"I enclose particulars of a self-acting model yacht I have made. She is 40 in. overall—*i.e.*, from stem to stern—13 in. wide, and 8 in. deep, with a false wooden keel 1 in. wide by ⅝ in. at stern, tapering down to ½ in. by ¼ in. at prow, and below this is a



Self-Acting Model Yacht Sails.

leaden keel of 22 lbs. weight, ⅞ in. by ⅝ in., tapering down to 1⅛ in. by ¼ in. at prow. Spars—Mainmast, above deck, 37½ in.; topmast, outside the head of mainmast, 26½ in.; boom, 37 in.; gaff, 23½ in.; jibboom, 25½ in.; fore staysail boom, 20 in.; bowsprit, outside stem head, 35½ in."

**Rate for Circular Saws.**—A Wood-Worker writes:—"*Do we drive our circular saws too fast?* This is the gist of a question put by F. A. M. on page 12, Vol. III. I am aware of the fact that machine saws driven by steam are driven very fast indeed, the limit being in the stability of the machinery—that is, its smoothness of running and absence of vibration. It is this last desirable quality that prompts makers to adopt the box pattern now so general, in preference to the older plan of several frames bolted together. But it may be that such velocity is not absolutely necessary, except as an essential to rapid sawing. Could we then saw at half the pace with a saw velocity reduced in proportion, and the motive power equally diminished? I believe we could. But it would be necessary to abolish *slip*, which is the bane of belt driven machinery. We are between two difficulties—a slack belt means slip, and a tight belt means waste of power, while all the applications of resin, etc., which may prevent slip, involve the loss of some power by the parting of belt and pulley, which is as inevitable as the movement. What is to be done, then, to secure the desired result at the least cost? Gearing is noisy, and not to be thought of; but it may be that we can learn a lesson from the cyclist. We know that if his rear-driving safety was connected with pedal by means of a very tight belt, he could not perform the great distances at the great speeds now so often accomplished. And if it were known to me how to alter a treadle machine in my possession, which now drives the saw by a leather belt, into a machine which drives with a chain, which need not be tight, but fits each wheel, I would experiment, and make the result known in Work. For some time past there has been an advertisement of a hand circular saw in Work (which was in the late Exhibition), and I believe it works well, although the saw revolves but slowly; the feed is in proper proportion, and there is no slip. Probably the teeth of the saw might need adapting to the speed, making the angle of clearance less, and making the tooth more a cutting tool and less a scraper; but if the space between the teeth is sufficient to contain the waste of the stoutest stuff it is used to cut, I think such a modification could but be of benefit."

### II.—Questions Answered by Editor and Staff.

**American Organ Coupler.**—Coupler.—The sketches given on page 633, No. 91, are correct, and do not require reversing as you suggest. Fig. 1 shows the bass coupler, which acts on the octave below the note touched; and Fig. 2 is the treble coupler, which acts on the octave above. The "A" end of the wires is pressed down by the button on the forepart of the key, and the "B" end presses on the collar or button on the plunger of the key an octave above or below, as the case may be. You ought to have no difficulty in arranging the wires and bending the flattened ends so that they will work without catching against each other, as the amount of movement is very slight. The platform need not be as much as 2 in. wide, and the wires need only overhang sufficiently to work. But the sizes of the various parts depend entirely on the amount of space available, and are not arbitrary. You appear from your sketch to have room for the coupler described without shifting the register or lath through which the plungers pass. As regards the broken screw in the reed plate, you may perhaps be able to move it by applying the edge of a small cold chisel to the head of the screw and gently tapping it with a hammer so as to cause the screw to be gradually moved round. After two or three turns, you would be able to get hold of it with the pliers and screw it out easily. If you cannot manage this, you might drill the screw out, but the first method is preferable. A hot wire held on the top of the screw and a drop of oil placed on it will facilitate the turning of the screw.—M. W.

**Coach-Painter's Outfit.**—Apprentice.—You want to know "where to get good pencils and varnish brushes," etc. There should be no difficulty in a town like Leicester to get all that you require. I purposely avoid saying, "Go to a good shop and pay a fair price"—advice often given in journals to inquirers. At the outset, the inquiry is for a good shop and about a fair price. Such a reply assumes that the querist will know a good shop when he sees it, and what is a fair price when the price is stated. A few questions to an old workman about paint-brushes and pencils will win you more information than any stranger's answer will help you to. But, in utilising your question for the benefit of others as well as yourself, it suggests a few remarks. It is nearly everywhere the rule for employers to find varnish brushes for workmen. All they are expected to find are the pencils for fine lines, stripes, or bands, a putty-knife, a stopping-knife, and a chisel-knife. The pencils are camel-hair, sable (red and brown), and ox-hair from the ear of the ox—nearly white hair—for some purposes. The ox-hair and camel-hair are mixed in pencils for striping. Coach-painters' pencils are known as "liners," as they are used for the lines on carriages, the hair being from 2 in. to 2½ in. long. The terms for sizes are by the quills in which they are held, the hand pencils being in goose-quills, stripe pencils in duck and crow-quills, and fine-line pencils in lark-quills. The short-haired pencils are known as the same, with the addition of the swan's-quill, for spot-work or carriage gear painting. These last an employer finds for his men. The prices of the "liners" are from 3d. to 1s. 10d. each. To try their quality, there is nothing better than drawing from the wet tongue over the lips, so as to saturate them with wet, and then spread them flat on a piece of glass with the fingers. They should feel free of knots, and, when flat, should be parallel-edged and square-pointed. In use they are not square-pointed by finely tapering; the flatting out on the glass makes them square-ended, where the separate hairs may be counted, so fine is the spread of the hairs under the fingers of the fine-liners. It is said of steel watch-springs, that they are dearer by weight than gold. These fine hairs of the Russian ox, sable, or camel are dearer than either by weight when mounted as pencils, and it may not be amiss to remark that gold intrinsically is a worthless metal compared to many others, or with such humble materials as hair, drugs, etc. Having bought your pencils—dearer than gold, some of them—you have to handle them with wood to suit the size of the quills. Soft cedar is a good wood for the purpose, as it is soft enough not to burst the quill when pressing it in. Be sure to file the part you poeket into the quill with a fine file; by holding the quill part in the mouth, or putting in warm water, it saves from splitting the quill; a little varnish on the dry point of the handle and in the quill cements them together. The putty and other knives are from 9d. to 1s. 6d. each. Just a word about taking care of pencils: you must not leave them in the paint-dipper for the paint to dry on the hairs; some paints are like glue, some corrosive. Wash them out with turpentine, wipe them dry, and draw the hair between the fingers as they hold a clean piece of hard tallow; spread the hair out flat and straight with tallow, enough just to make them stick to a bit of clean panel or glass, and put them thus into a small box or tray-draw. This tallow is easily washed off before using again. A good plan to compare prices is to get a price list from two or three makers. They will not vary much: the most intelligently written and illustrated one will doubtless commend itself to you. J. B. Smith, 117, Hampstead Road, London, N.W., issues a 42-page catalogue, fully illustrated, as do many other firms whose names I forget.—J. C. K.

**Book Sewing.**—One in Trouble.—Read the articles upon "Bookbinding" in Vol. II. of Work, where all instructions are given for sewing books. If you follow the details there given, you may be able to sew your volume.—G. C.

**Phonograph.**—The article on the above, with working drawings, will be published when space can be spared for it. I hope you will find them answer your purpose, and that you will be able to make the instrument.—W. D.

**Telephone.**—R. A. D. (*Forest Hill*).—From the meagre description you give it is impossible to tell what is the matter with your telephones. Your magnets may not be strong enough, or too near to, or too far away from, the diaphragm. Or the diaphragm itself may not be tightly clamped. You want a transmitter and battery to get good speaking results.—W. D.

**Enlarging Photographs.**—Nil Desperandum does not say if the photographs are paper prints or transparencies; in any case there is no necessity to injure them. If on paper, they must be fixed on a flat surface in a good light, avoiding reflections, and a negative made of them in the usual manner. If on glass—that is, glass transparencies—they must be placed so that a strong light is reflected *through them*. A large sheet of white cardboard is the best reflector, set at an angle of 45° behind the transparency—all other light except that passing through the transparency carefully shielded from the lens. A negative is now taken in the ordinary manner.—D.

**Whole-Plate Camera.**—H. B. (*Hammersmith*).—If you refer to the first volume of Work, you will find full instructions for making a whole-plate camera. The size you want is for plates, 6½ in. by 4¾ in. You can easily reduce that given to suit this measurement; you may make it somewhat lighter all through. If you can grasp the principle of the thing, you will have little difficulty. To give drawings, measurements, and text, would occupy too much space in these columns. You can get the metal and other fittings of Parks, 1, Orchard Buildings, Kingsland Road, N., and the lenses of any photographic material dealer; there are scores in London. The kind of lens depends very much on the kind of work required. The best kind of lens for general work would be either of the rapid rectilinear or symmetrical type. The portrait form is not suitable for anything else but portraiture, the field being too round. The size of the stand is very much a matter of taste—about 5 foot is an average height. You will find diagrams and descriptions of this also on referring to the back numbers of Work.—D.

**Roller Model.**—J. G. (*Aberdeen*).—The necessity for rollers or castors under heavy drawers is by no means so great as you seem to suppose, and to have them under drawers no larger than those in an ordinary dressing chest would be quite superfluous. As a matter of fact, your idea is by no means a new one, for I have known of similar contrivances being used for many years whenever required. The ordinary sash roller is far better for the purpose than the model you send, which, from a practical tradesman's point of view, is defective in many respects for general purposes. You will thus see that I cannot hold out any hope of your making a success with the article if you were to incur the expense of patenting it. In case you wish to try what chance you have with your roller in the open market, submit your idea to any of the Birmingham cabinet brass founders.—D. A.

**Water in Gas-Pipes.**—S. M. (*Kidderminster*).—From the fact that where dry gas meters are used there is seldom, if any, trouble about water in the pipes, I conclude that it is caused by a certain amount of water being brought into the pipes from the water that is used in a wet meter. Put a syphon in the lowest part of your pipes with a small tap, which, if turned off now and then, will remedy the defect.—R. A.

**Incubator.**—Chicks.—An article on "How to Make an Incubator" appeared in No. 89 of Work.

**Home-Made Furniture.**—S. C. (*Ashton-under-Lyne*).—You may send photographs of any of your home-made articles, together with descriptions of how you made the same. If suitable, publicity shall be given them.

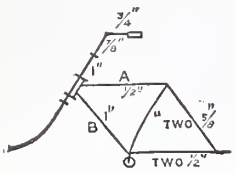
**Japanning Oven.**—E. H. (*King's Cross*).—The temperature of your oven should range from 260° to 300°. It is advisable to stove the ground colour first, and then put on the decoration, and stove again at a little less heat. For paints, japans, and medium for applying gold-leaf or bronze-powder, apply to Mander Brothers, Varnish Manufacturers, Wolverhampton; or to Wilkinson, Heywood, and Clark, Caledonian Road, N. Works: West Drayton, Middlesex. Either of these firms will supply your needs.—R. A.

**Ice-Cream Freezer.**—J. C. (*Belfast*).—It is a very simple affair, and consists, as you are perhaps aware, of a pewter cylinder with a bottom, and with a well-fitting cover. You do not state what size you require it to be, and not knowing your trade or what tools you have, it is rather a difficult matter to advise you upon; but, however, here goes. To make one 15 in. deep and 6 in. diameter, get a piece of pewter ½ in. thick (or a shade less will do), 18¾ in. by 15 in. If you can get a tinsmith to turn it round for you in his rollers, it will save you a lot of trouble; if this is out of your power, you can bend it round on a piece of iron pipe, 4 in. or 5 in. in diameter, or on a round piece of wood. Let the edges "butt" together—not "lap" them—and solder down the seam with a hatchet, soldering-iron, or a blow-pipe. Cut a circular piece, and solder in one end for the bottom; file off all superfluous solder, and scrape smooth. For the lid, cut out a rim 2 in. in depth, and long enough to go round the outside of the vessel just described; solder as before, and solder a similar circular piece to the one in the bottom; if you can hollow it up, it will look all the better. Then bend a piece of tin or lead pipe to form a handle, and solder it on to the lid, and the affair is completed. Finish up with glass-paper and a burnisher if you want it to look anything.—R. A.

**Telegraph Wires.**—Ned.—Lay the line wire in the groove of the insulator on one side. Pass one end of the binding wire over the line wire to the left of the insulator; form this part of the binding wire into a loop, and hold this in the left hand. Then pass the other end of the binding wire over the line wire to the right of the insulator, draw it tight, and then bring the line into the insulator groove on one side, whilst the binding wire is pulled tight into the groove on the opposite side. Pass the right-hand end over the line to the left,

and the left-hand end over the line to the right; pull both well into the groove, then twist the two ends together with a pair of stout pliers, and cut off the surplus ends. Each wire end in the $\frac{7}{64}$ cable must be separated and cleaned with emery cloth to the length of 2 in.; these cleaned ends must be spliced or twisted together, moistened with soldering fluid, and soldered in the ordinary way. Wipe clean with a rag, and bind the joint with tarred tape. After this is done, restore the outside insulating and protecting covering.—G. E. B.

**Light Roadster Bicycle.**—A WELL-WISHER OF "WORK."—The weight of tubing for a light roadster or racing machine would be all over 15 in. B.W.G., the thickest tubes would be 1 in., and smallest $\frac{1}{2}$ in. The spoke wire, if for direct spokes, would be No. 10, 11, or 12; if for laced or tangent wheels, No. 15 is heavy enough. Handle bar may be bent by heating to a bright red the part you wish to bend; grip the straight part in a vice—that is, the end part where the handle will be placed—and use the remainder for a lever; it will thus be readily bent. If the bend is somewhat quick, the part bent will incline to oval: this may be cured by hammering carefully on a smooth anvil. The only other bent tube is the seat tube, and it may be bent in the same way. See that as much of the tube as you wish to bend is heated at once, and equally. The sketch given above has marked on it the thickness of the various tubes composing the frame. Some diamond frames—such as the "Referee" and "Swift"—have the tubes A and B both $\frac{5}{8}$ in.; so it is a matter of choice. For an ordinary heavy roadster all the tubes would be $\frac{1}{2}$ in. heavier than indicated in the diagram.—A. S. P.



Bicycle Frame.

**Amateur Printing.**—ELEVEN.—Information as to the cost of requisites for this work may be had from the Model Printing Press Co., 3, Ludgate Circus Buildings, London, E.C.; or from the Birmingham Machinists' Co., Parade Iron Works, Birmingham. As he is something of an amateur workman, ELEVEN thinks that if he knew how to set about it, he might make a press for himself. I think so too, and will, if he wishes it, help him to full directions for constructing a small press.—S. W.

**Home-Made Camera.**—W. J. U. (*Leytonstone*).—An article on the above appeared in WORK, No. 70. It will probably suit you.

**Oilstone.**—RISHTON.—You would be able to procure the stone you require from Mr. R. Hickman, Worcester Street, Wolverhampton. I do not know of any book on the subject of cutlery.—T. W.

**Hinge and Catch.**—J. E. W. (*Camberwell*).—I have seen such spring hinges and catches as you refer to, but they are by no means common, and at the time of receipt of your letter I was unable to say where they could be obtained. However, as the result of inquiries among the cabinet brass-founders in Birmingham, I find that Messrs. R. Gardner & Co., 66, Granville Street, Birmingham, can supply you with them.—D. A.

**Medical Coil.**—A. B. (*Accrington*).—A series of articles on "Coils" is now in course of preparation. In these a medical coil will be fully described and illustrated.—G. E. B.

**Pipe Mounts and Ferrules.**—J. D. (*Dundee*).—To make an ordinary pipe mount, a plate of silver has to be prepared exactly the size, or perhaps a shade smaller than will fit tight round the two pieces that are to be joined by its means. The easiest way to obtain a pattern of suitable size and shape for this plate is by wrapping a piece of smooth paper round the place where the mount is to go, and very carefully cutting all the surplus away with a pair of scissors until one thickness of the paper is all round the pipe. If this is well done, due attention being paid to the straightness of the soldering seam and of the ends, then the silver can be cut to it exactly. The next thing to do is to get the plate flat, and then proceed to turn it up into a tube quite free from bruises or kinks. For this a "triblet" is required. It is nothing but a piece of smooth, round, tapering piece of iron or steel and a bending block, such as is figured in No. 41, page 648, Vol. I. of WORK. A mallet also may be necessary if the silver is thick; if it is not, then it will come up by the pressure of the hand almost; or, in place of block and mallet, a pair of half-round pliers will do if the silver be rather thin. For mounts of less than an inch in length, I should say size 6 Shakespear gauge would be plenty stout enough. The next step is to fit the soldering seam so that the two edges are quite level and true with each other; see also that no burr from the file is left before tying with wire. A scraper, made from a three-square file, is usually the tool used, but a knife will do as well. Should the mount be long, it would be well to file small nicks in the edges that form the seam (as shown in Fig. 1, *a a*), for the solder then holds better, and will not be so likely to open during the later operations it has to undergo. When fitted, it has to be tied with iron binding wire in such a manner that the edges of the seam are retained in their places during the operation of soldering. Wire should not be used too thick, as in cooling it will shrink, and may bruise the work. In most cases the tying of the wire will not be difficult, but it will be so when the mount is very taper (as in Fig. 1). Here there are means taken to prevent the binding wire slipping down, which, I think, needs no further explanation than the sketch. Many of the details of soldering are given in No. 37, page 588, and No. 46, page 732, of Vol. I. of WORK, so that can be passed over here, and we can proceed with the mount after it has been soldered and "pickled," and all pieces of unflushed solder filed away. The mount is sure to be more or less out of shape now, so we have first of all to get it true and smooth; this can be done pretty well on the triblet, previously spoken of, with a smooth-faced mallet. A lathe would be useful at this and at the polishing stages, but we are to do without it. So if the triblet and mallet or hammer will not get the mount smooth (and it will not if very thin metal is in use), then it will be worth while to get made a kind of ribbed burnisher (as shown in Fig. 2). I do not know that this is made and used generally, but with it it is quite possible to rub the thinnest of collars true and smooth. The size of it would be from 7 in. to 10 in. long, and about 1 in. wide; the thickness will be $\frac{1}{16}$ in, or thereabouts. An old flat file can be made to do capitally. The ribs or ridges should be quite smooth, and the size shown in sketch will do for their average size. The sketch shows only part of this tool, for I have not the presumption to ask for space to illustrate it at its full dimensions. Somehow or other we will suppose now that the mount is in shape, and fits the pipe; therefore we have but to smooth it up and polish it. It may need filing to remove hammer marks, etc.; if so, then get them out at once with the file. Do not depend on glass-paper or emery-cloth. These two

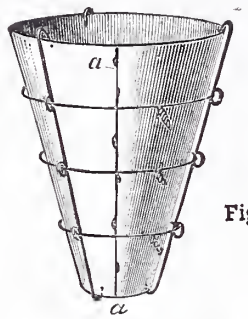


Fig. 1.

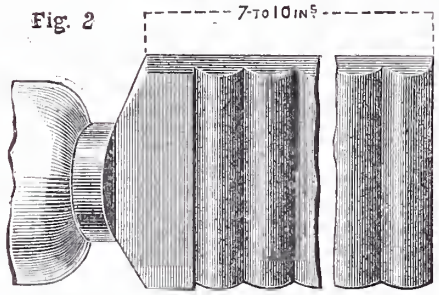
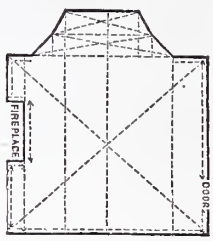
Fig. 2



Pipe Mounts and Ferrules. Fig. 1.—Mount. Fig. 2.—Ribbed Burnisher.

articles are very useful in their way, but they tend to make the corners rounding when they should be sharp. Either can be used after filing, but use the smoothest quality. The next thing is to polish the mount. The theory of polishing is a simple one. It is the application by friction of abrasive materials in stages of gradually increasing fineness. If that theory is understood, it will be easy for this correspondent or anyone else to make shift with materials to hand. Those I now speak of are the proper articles, a lathe not being allowed. As the mount we are to polish may be thin, and therefore likely to get out of shape, it will be best and easiest to fit a piece of wood to it, which will serve the double purpose of supporting it and of allowing it to be handled with comfort. The first thing used is a stick of water of Ayr stone; this is used with water, a damp sponge being employed to remove the mud-like stonings as they are produced. The next polishing material is powdered pumice-stone and oil; after that, crocus and oil (or rotten-stone or Tripoli powder and oil). Any or all of these are to be applied by means of buffs charged with them. A buff is merely a strip of buff leather (soldiers' belts), glued to a piece of wood. With these and plenty of elbow grease the mount will soon become bright and smooth. Next brush it with damp whiting (not too hard a brush, please), and then wash it in hot soda and water to remove every atom of grease and other polishing material. In rouging—tools, rouge, hands, all must be clean and free from grit. Use a buff at first; then charge the palm of the hand or ball of the thumb for finishing, thus using the skin as a finer kind of buff. After washing once more to remove any rouge there may be, the mount is ready for fixing on. Each material used must be entirely removed from the work before the next finest is used, and for that reason separate buffs are to be obtained. They only cost about 3d. each; and as for the other polishing materials, the water of Ayr stone, the crocus, and rouge can be obtained in three-pennyworths or thereabouts at any jewellers' material shop. Powdered pumice and whiting can be got at any oil-shop, for they are used in the household. There are other materials used, but these are sufficient for the present jobs. With reference to ferrules for the ends of sticks, the same set of processes has to be gone through; they are, however, less carefully finished. With reference to the plate at the end, which is to stand the wear—What is to be put in? Steel, iron, or only a thick metal plate? Whatever it is, pewter solder seems good enough to hold it. These ordinary ferrules can be bought so cheap that, except for practice, nobody would make them.—H. S. G.

**Carpet.**—WEST KENSINGTON.—Had you stated exactly where your difficulty lies, I could no doubt have done something towards removing it, but apparently you want to be told all about carpet planning, which really cannot be done in "Shop." It may be that you want to have a definite rule to go upon in all cases, a sort of "guide to carpet planning in a nutshell," and, to accommodate you as far as possible, the best advice I can give you is to use your common sense, and not to be afraid of taking all measurements with the greatest accuracy. Something near the mark will not do. Be careful to take not only the measurements along the walls, but take them from angle to angle wherever there is an opportunity of doing so. These will materially assist you when you proceed to set out the full-sized plan of the room—in fact, you cannot do without them. When measuring, take down on a sheet of paper a rough plan of the room, and mark in position the various dimensions. The carpet itself will be best fitted and made to a full-sized plan, which you can mark out on a large floor with chalk. To give you some idea of measurements, the small diagram which accompanies this will be useful. As it is necessarily on a small scale, the measurements are not stated. You will understand that the dotted lines must be measured, and, of course, round the walls. Experience only can teach a man to know exactly what cross measurements are absolutely necessary. As a beginner, you will find it better to take too many than too few. Act on the reverse of the saying, "When in doubt leave out," by putting in all that may assist you when planning the carpet, even though you find afterwards that some of it is superfluous. If you attend to this brief advice on a very wide subject, and use your brains, you will not make any very serious mistakes.—D. D.



Carpet Measure Plan.

**Potash Battery.**—VOLTAGE.—It is several years since I had anything to do with the battery made up of iron turnings and black potash, but I have some remembrance of its voltage being slightly less than the Leclanché—say, about 1·2 volts. The internal resistance of the quart size, when first made up, was a trifle less than that of the No. 2 Leclanché cell. It was simply a modification of the Bennett battery, black potash being substituted for caustic potash. Its chief merit lay in its low first cost, as it could be made up out of old tin pots, iron turnings, and scrap zinc.—G. E. B.

**Battery Carbons.**—OBLONG.—(1) Battery carbons may be made of very finely powdered gas carbon and wood charcoal sifted free from lumps and mixed in the proportion of four parts carbon to one part of charcoal. The mixture must be made into a stiff paste with a sufficient quantity of treacle, and pressed very tight into an iron mould, which must then be tightly closed, heated to a bright red, and allowed to cool slowly. When the mould is cool, take out the carbon plate or bar, soak it well in the treacle, place again in the mould, and again heat the mould to a bright red. Repeat this treatment until the carbon has been rendered sufficiently dense and hard. (2) Before attempting to cap the plates, see that the carbon is quite dry. Let the heads stand well above the tops of the cells, and paint them whilst still hot with a sufficient quantity of Brunswick black to soak well into every crevice beneath the head and down the plate to the depth of $\frac{1}{2}$ in. below the head. If you do this well, I think you will not be troubled with corroded heads. (3) I have not had any experience with baked manganese, but should think the process doubtful as a means of restoring oxygen to the partly exhausted manganese.—G. E. B.

**Water Power.**—A. B. (*London*).—Three gallons of water weigh 30 lbs., therefore the gross power at your disposal is 40 ft. × 30 lbs. = 1,200 ft.-lbs. per minute. As one horse power is 33,000 ft.-lbs. per minute, your gross power is equal to about one twenty-eighth of one horse power—rather less than half a man power. A small turbine will be the best motor for you to use; a good one will utilise about 75 per cent. of the total power, and so give 900 ft.-lbs. per minute, or one-third of a man power. The Index to Vol. II. is published and can be had, price 1d.—F. C.

**Solder for Albo-Silver and Aluminium Gold.**—V. T. (*Galley Hill*).—This correspondent says he cannot obtain satisfactory results with spelter solder. Now, in very many cases it is the lack of scrupulous cleanliness that causes difficulty with the proper fusing of solders. Is the borax clean, the water clean, the spelter clean, and the work well scraped?

Is the flame used to solder with a clear and not a smoky one? If all of these are answered Yes, then it will be the spelter solder that is in fault; so when next either alho-silver or aluminium gold is hought, the proper solder should be asked for. I have not had occasion to work the albo-silver, but the makers of that alloy (Messrs. Reading & Co., of Warstone Lane, Birmingham) tell me that they have a special solder for it, which is sold at 4s. per lb. For both of these alloys the ordinary silver solder that can be hought at jewellers' material shops will do all right—that is, if the aluminium gold which I have worked is the same as that you have. The proportions of aluminium and copper will very probably vary with every maker, so it is quite prohable that I may be wrong in your special case; hence it will he best to do as I say above—obtain the solder from the same place where the metal is bought.—H. S. G.

**To Clean Silver Filigree Work.**—E. B. (*London, E.*).—The only ways to restore the dead white surface to silver filigree are:—First, by having it put in the plating solution, when a fresh coat of fine silver can be deposited on the surface; or, secondly, hy annealing and pickling it. Tbis last process will hardly do with stock work, as in time the article would be destroyed through the gradual removal of the outer layers of silver, for it is hy refining the surface (taking all the alloy out, that is) that the pure silver coating is obtained. The means I take to make silver presentable is as follows:—Make whiting into a paste with a solution of half water and half liquid ammonia; then, for this class of work, I cover it completely with the paste, and leave it for a quarter of an hour or so; then wash thoroughly in boiling hot water, well rinse it also in boiling water, and then, without any exposure to the air, it is next to he covered up with hot clean hoxwood dust, until it is thoroughly dry, when a soft brush can be used to remove the sawdust. This diluted ammonia with whiting is a good thing to use with ordinary hright silver work, where a brush can be used to apply it. Of course, a hrush is hardly suitable here, as the work must be kept as dead as possible. If the filigree is made of really fine silver, then it might be worth while to try the Indian method, as described hy G. E. Gee, on page 142 of his "Silversmith's Handbook," as follows:—"Some juicy lemons are cut into slices; the silver articles are briskly ruhhed witb theso for a short time, and subsequeutly covered with them, being placed in a suitable vessel for a few hours for the completion of the process. For very delicate articles of jewellery, the natives cut a large lime nearly in two halves, into which they insert the work; the halves are then tightly closed up again, and placed aside for a few hours. When the article is removed, it is well rinsed in clean water, and consigned to a vessel of nearly hoiling soap-suds, wbere it is well brushed, again rinsed in fresh hot water, and finally dried on a metal plate placed over hot water; the process is rendered complete by a little gentle rubbing if the work be of a plain nature. Green tamarind pods are also employed hy them for the purpose of whitening silver, in the same manner as just described; they are great detergents of both gold and silver manufactures, and are largely employed by artisans in the East for the removal of oxides and fire-marks." In the above quotation, the drying of the articles does not seem to be so thorough as it will be if the hox sawdust is used, and is heated in a basin or other receptacle surrounded by hot water. The sort of thing best to use is something on the principle of a "Bain-marie pan," used in cooking, or else that of a glue-pot. Dry heat is too risky, for one can say good-bye to nice white work, if ever so small a portion of the boxdust gets burned. If the Indian method is tried, all metal tongues or joint pins will have to be taken out.—H. S. G.

**Geneva Watch.**—AMATEUR.—It is impossible to help you, as you give no particulars. Take it hack to the watchmaker who did it, and do not pay for doing it till it goes.—A. B. C.

**Current from Battery.**—A. M. (*Rochdale*).—If you have not a galvanometer to detect the current, you may still tell whether current is passing or not by the following simple device:—Connect two wires to the battery, one to each pole; clean the two free ends, and place them on your tongue; then bring the ends together on the tongue. If current is being given off from the battery, a sharp acid flavour will be tasted at the moment of crossing the wires, and this flavour will be sharper when the current is vigorous than when it is sluggish. You cannot feel the current in your hands. After mixing the acid with water, allow it to cool before placing it in the cells, then it will not "hurn away the zinc." Of course you know that the zinc must he coated with mercury before using it in a chromic acid battery. I do not know the depolarising liquid used by Dr. Gassner. Try soaking in Condy's fluid disinfectant. The copper wire is soldered to the top of the zinc cylinder. It is merely in place of a binding screw, but I prefer the screw.—G. E. B.

**Clock Designs.**—AN APPRENTICE MASON.—If you wait patiently, some designs for clock cases will be given. Freestone is scarcely to be recommended as a material for clock cases.

**Wire for Electric Bell.**—A. P. S. (*Heaton Chapel*).—The two bobhins 2 in. by ¾ in. will take about 92 yds., or about 9 ozs. of No. 24 silk-covered copper wire, and this will cost somewhere between 1s. 3d. and 1s. 6d. A papier-mâehé tube will do very well for the body of the bobbins when fitted with hard wood collars for the ends. Be sure to glue these on firmly, or the wire will push them off. Also have the tubes thin, so as to get the wire coils as closely as possible to the cores.—G. E. B.

**Sanitary Rail.**—MEDICUS.—A simple and effectual method of admitting fresh air into ordinary dwelling-rooms is shown in Fig. 1. It consists of a piece of wood fitted tightly in between the sash heads on top of the inside of window-sill, and secured hy small dowels at bottom and two blind holts on top, so that it can be removed for the purpose of cleaning windows, and that on raising the bottom sash 2 in. or 3 in., a current of fresh air is admitted between the meeting bars in the direction shown by arrows. The meeting bars of an ordinary

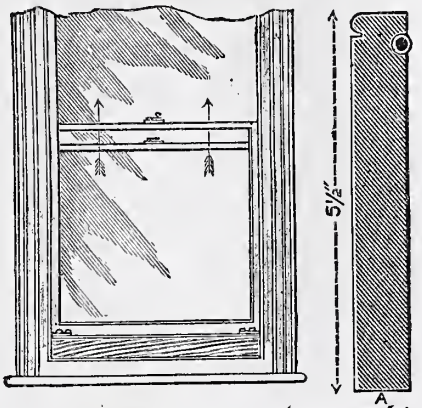


Fig. 1. Fig. 2.

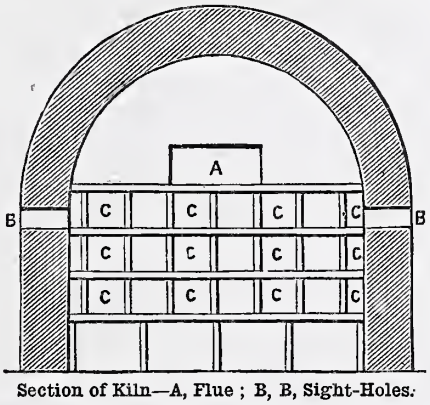
Sanitary Rail.

hung sash being above 6 ft. high from the floor, and the current of air directed upwards, persons in the room feel no inconvenience. Fig. 2 shows the end view of rail with a piece of indiarubber piping inserted and glued in a hollow groove, against which the face of the hottom rail of hottom sash slides, and thus prevents a draught at this point. I generally put a similar piece of piping along the hottom of rail to make a good joint down on the bead at A. The ventilation of a room would be very much more complete with the addition of an outlet ventilator into the chimney, or any other convenient point as near the ceiling as possible, to ensure a thorough change of air by continuous circulation.—E. D.

**Kiln.**—ANTONIO.—The simplest method of building a kiln is to form a square or ohlong chamber, arched at the top; it should be lined with fire-hricks set in fire-clay, and backed up outside, or hooped with iron, to prevent it giving way from the heat. At one end a furnace with grate bars is formed, and having a vent over the door for the admission of air, with a sliding fire-brick lump to regulate it. Inside the chamber a number of spaces are formed



Section of Kiln—A, Flue; B, B, Sight-Holes.

of fire-brick, and covered with fire-brick lumps set in fire-clay. The figures are placed in each alternate space, and the flame and heated air from the furnace are arranged to pass through between each space occupied by the articles to be fired. The sketch above is a section of the chamber, the spaces marked C,C,C, containing the articles; and the flame passing through the remaining spaces, and escaping at A into the chimney. The chimney should he 20 ft. or more in height, so as to have a good draught. The fire is put away slowly at first, till the kiln is heated throughout; it is then urged to the requisite heat for burning the articles, which is tested by having pieces of clay put in at the sight-holes, B, B, at each side: these are examined from time to time till of the required degree of hardness. The sight-holes are covered by fire-brick lumps, and the draught is regulated by admitting more or less air over the furnace door. As soon as the articles are sufficiently hurnt, all the openings are closed up, and the kiln allowed to cool gradually. If you only have a few articles to burn, you will find it more economical to send them to some works to be burnt than to do it yourself.—M.

**Lacquering.**—A. B. (*London, N.E.*).—Lacquering can scarcely he called a "trade hy itself." I should think it might be more correctly called a hranch of the hrass-finishing trade, though there is this to he said ahout it: that in large establishments there are persons employed solely in lacquering. I am not aware of any classes for practising lacquering, nor of any hooks bearing specially on the subject. There is some information on the subject in Spon's "Workshop Receipts" (First Scries), which would be of use to you. With regard to the latter portion of your letter, where you ask, "Has one a chance of a job who has had some practice at filing and finishing and lacquering" hrass?—to this I can answer, Yes; such persons are frequently advertised for in the *Daily Chronicle* and other papers. My advice to you is to get into a good shop as improver, at whatever salary you can get, and make the hest use of your eyes and ears. You would then, if diligent, soon be capable of taking a hetter job.—R. A.

**Microscope: Where to Buy It.**—W. W. (*Wensley*).—See reply to B. G. F. (*Bristol*), and for trade catalogues, with prices of microscopes of every description, write to either of the following firms for catalogues:—Mr. E. G. Wood, 74, Cheapside, E.C.; Messrs. Watson & Sons, 313, High Holhorn, W.C.; Mr. J. H. Steward, 406, Strand, W.C.; Mr. J. Browning, 63, Strand, W.C.; or Messrs. Sands & Hunter, 20, Cranbourne Street, W.C. If you only require a very cheap microscope, I may tell you that Messrs. Lancaster & Son, Colmore Row, Birmingham, used to make up a cheap botanical microscope—one power, 1s.; two powers, 2s. 3d.; three powers, 3s. 6d.; table microscopes, mounted on three feet, from 2s. 6d. The same firm used to supply amateurs with a set of lenses for making a compound microscope with a power of 200 diameters, and a lithograph and instructions, 3s. 6d.; or the same with a power of 400 diameters, 5s. 6d., and power of 600, 7s. 6d. Set of achromatic lenses as above, with a power of 200 to 400, 10s. 6d.; or power of 600, 21s.—C. A. P.

**Books on the Microscope.**—B. G. F. (*Bristol*).—A cheap manual dealing with the microscope is published hy Mr. E. G. Wood, 74, Cheapside, E.C., under the title of "The Microscope: How Made and How Used," price 6d., post free, with a trade catalogue. If you require a more advanced work, you should get "Lancaster's Half-Hours with the Microscope," 2s. 6d.; "How to Choose a Microscope," by a Demonstrator, 1s.; "Objects for the Microscope," Lane Clarke, 3s. 6d.; "Handbook of the Microscope," Griffiths, 7s. 6d.; "Practical Microscopy," G. R. Davis, 7s. 6d.; "Hogg on the Microscope," 7s. 6d.; "Carpenter on the Microscope," 15s.; "How to Work the Microscope," Beale, 21s.; "Tuckett on the Microscope," 22s. If you want a trade catalogue, see above reply to W. W. (*Wensley*).—C. A. P.

**Filling Lamps.**—S. B. (*Upper Holloway*).—We have examined and considered sketch and description sent, and are of opinion that it is ingenious, practical, and likely to be useful if properly put on the market, but we cannot see our way to introduce it to the notice of anyone likely to join the inventor, as he would have to trust entirely to the *bonâ fides* and honesty of those treated with, who, when they know as much as the inventor, are too apt to think they can do without him, and in far too many cases take an unfair advantage of the information they have obtained. The only safe course we could advise would be to make a careful search at the Patents Office to see if there is anything of the kind recorded, and if not, then to lodge the provisional specimen, and so soon as it is accepted, he will then he perfectly safe in treating with anyone who may be disposed to join. We should hesitate to incur the responsibility of advising any person to treat for capital for an unprotected invention with anyone he does not know, and know well.—C. E.

**Electro-Motor.**—MAC.—As you have Mr. Bottone's book on "Electro-Motors: How Made and How Used," I need only direct you to its pages. On pages 29 and 32 you will find illustrations of a compact form of motor. The "Simplex" motor, shown on page 59, is also a compact form. If you wish to know how to make a small motor to run with current from one chromic acid cell, consult section 34 of the book, on pages 60 to 63. You will get very poor results, however, from a motor worked with currents from only one pint chromic acid cell. The zinc in a cell for driving a motor should have a surface area of not less than 16 sq. in., and three such cells should be provided. The poor results complained of are, I fear, due more to the workmanship than the design. I have described and illustrated in WORK a very neat and compact form of motor introduced hy Mr. H. Atkinson, 137, Stamford Road, Handsworth, Birmingham, who will supply the castings for 3s. 6d. Perhaps this may suit you, but it will not do any useful work—or, in fact, any work at all—with only one pint chromic acid cell.—G. E. B.

**Pocket Battery.**—J. K. (*Bury*).—When lead plates are used in making a pocket battery, the cells are charged with a mixture of sulphuric acid and water. There are pockct batteries that are not charged with liquid, such as the silver chloride and mercury chloride series of batteries, in which the negative element of silver, platinum, or carhon, and the positive element of zinc, is coated with a paste of the exciting salt. The Gassner is also a dry battery. Some of these are regenerative, and therefore may he classed among secondary batteries, but they are not furnished with lead plates. You will find an account of a pocket battery in the eighth of the series of papers on "Model Electric Lights"

published on pages 790 to 792, Vol. II. of WORK. —G. E. B.

**Fishing Rods.**—J. N. B. (*Liverpool*).—If you will look on page 802, No. 102, Vol. II. of WORK, you will see that the subject has already had attention. —D. D.

**Sideboard.**—E. A. P. (*Beckenham*).—For the purpose of selling the job, you might estimate the cost of material and the value of the time. Even though you have not kept an account of this, you have probably some idea, and it will be much fairer to base your charge on this than on an idea of the value from anyone who has not seen the job. If you and your customer cannot agree as to value, get a valuer to assess it.—D. D.

**Polish.**—J. T. (*Merthyr Tydfil*).—The simplest and best way of making French polish is, as has been several times stated in these columns, by simply dissolving shellac in methylated spirit in the proportion of about 6 oz. or 8 oz. to the pint. The cause of your dissatisfaction with the result of the polish you are at present using probably arises not so much from the resin it contains as from want of skill in applying it. The resin should not prevent a good gloss being obtained; and I take it that this is where your difficulty lies. You may use a filling if you like, but you will find it a very difficult and tedious matter to clean it out from corners. On this account fretwork is seldom filled by polishers. If you have not already fretted the wood, polish in the usual way as far as bodying in before cutting, and afterwards finish by spiriting off. If you do not care to take the trouble of polishing, go over the work with spirit varnish.—D. D.

**Improving One's Position.**—H. B. (*Dudley*).—Have your past services been of such a character to your employers that they may be induced to remove you into the main works as a reward for past services faithfully and intelligently rendered? If so, they may entertain a request from you, although it would best suit them to allow you to remain where you are. Could you do better by obtaining work in a small country wheelwright's shop, where you may gain a more general insight into a greater variety of work? I do not recommend you to try model making; but if you have made any articles worth showing them, it may help you by calling your employers' attention to them. There are other roads open to you. I have a young fellow near me who has been doing the rough woodwork in a brickfield for years, but has also learnt himself wood carving at home. Another one especially, who, until he was twenty-eight years old, worked as striker at a forge, and at forty was in charge of one of the best and most complicated machines in a large engineering shop; he, like all the others, was steady, clever, obliging, and would never be beaten.—WORKER BEE.

**How to Clean Brain Coral.**—W. A. P. (*Hackney*).—For a piece of rough coral with very delicate portions like this, the easiest way to clean it will be by using an acid, and dissolving away the present dirty surface—that is, if merely washing in hot water will not obtain the desired result. Either nitric, sulphuric, or hydrochloric acid (spirits of salts) can be used; but as I know the last is best, I advise using that. It does well with ordinary branch coral in the proportion of $\frac{1}{16}$ to $\frac{1}{20}$ acid to water. A minute or so of immersion should be sufficient to remove the very small depth of outside surface that is necessary. Unfortunately, I have no specimen of this coral by me to experiment with, but I should proceed as follows:—Make the mixture as given above, and dip an unimportant lower part or end, and see what the result is. Whether trying the whole piece or only a portion, be sure to have plenty of warm water ready for rinsing the whole piece, and so stop the action of the acid. It is easy to see if the acid in the water is present in sufficient quantity, for if it acts it shows that it is acting by giving off a stream of bubbles. The stronger the acid, the greater rapidity the bubbles are given off. In order not to complicate matters, see that there is no grease on the piece of coral. Washing in hot water will get rid of grease, particularly if a little soda be mixed with it. It must be well rinsed in hot water, with no soda, and shaken nearly dry before placing in the acid bath.—H. S. G.

**Tools and Machines.**—W. T. R. (*St. John's, Newfoundland*).—Section I. of "Shop" is specially designed for the expression of ideas interesting to readers of WORK. If, therefore, you have any tools or machines of novel character likely to be interesting to workers, by all means send us on sketches of them, with particulars of what they will do. All other readers are invited to note this.

**Rabbit Skins.**—W. B. W. (*Wolverhampton*).—Whatever you have to say to E. H. H. upon this subject you should say through the pages of "Shop," for the benefit of all readers.

**Wax-Polishing.**—BEACON.—If, as you say, you have tried wax-polishing and cannot do it, I am afraid you must give up all hope of ever being able to polish anything by any method, for it is the simplest there is. I am inclined to think you have omitted to use elbow grease with the wax and turpentine. As you say you cannot find anything about wax-polishing in WORK, let me refer you to page 826, No. 52, Vol. I., where you will find the subject has been fully treated by Mr. Denning. —D. A.

**Incubator.**—JAMES.—It is clear that your lamp-flame is insufficient. Try a circular burner: the kind known as "Kosmos" is the best, and is obtainable at any dealer's. Should you find the chimney too long for the case you have already made, you can easily shorten it by filing a "nick" all round at the required length, and then gently knock it off. It will not materially affect the burning of the lamp.—C. M. W.

**Bell Fittings.**—ANXIOUS H. F.—If you send four stamps to Messrs. Baughan & Co., Charlbury, Oxford, they will send you an illustrated list of electric bells and fittings, which also contains a short description of how to fix them. Perhaps you could obtain a list of cranks, etc., from an ironmonger in Sheffield. I do not know of any list out of the trade.—T. W.

**Fret Machine.**—SAWYER.—The "Companion" lathe and fret saw is a good one so far as value for money is concerned, but you must understand that from its small size its turning powers are limited. If you only want to turn small articles, it may suit your purpose. The fret-sawing attachment is useful, and is a good arrangement of its class of machine—viz., that with movable arms. If you contemplate doing anything but small work, I should recommend you to lay out a little more money than the figure you name, and buy a really good fret machine and lathe separately, as the ordinary combined lathes and saws are naturally only suitable for small light things. The fret machine I recommend to you is the Britannia Company's "Improved No. 8," and you could have a lathe attachment to it, though it is not usually sold with it. I am told that the Britannia Company are devising a special lathe attachment for the No. 8, so by the time you see this answer to your inquiry they may be able to give you all particulars if you write to them direct. Their endeavour is to supply a serviceable attachment for somewhere about a sovereign. Their fret machine having a heavy wheel, naturally there will be a proportionate increase in power for turning. If you prefer the "Companion" style of machine, I think you will find the "Goodell" worth the extra amount charged for it. It is in all essential features the same as the others. The cutting of wood you send is too small to tell the kind of timber, but it seems to be sycamore, though, as your local dealer did not know, it may possibly be some other kind. Perhaps the colour misled him. Any way, it is simply a piece of white or light-coloured wood dyed grey, and can easily be got from fancy wood dealers and fret supply stores. Ask for grey wood or silver wood. Yes, it can be French polished.—D. A.

**Bicycle Enamel.**—J. P. (*Bethnal Green*).—You should rub down the parts of bicycle to be painted with emery-cloth or glass-paper, then wipe clean with a cloth; then procure Club hard drying black enamel, and apply it evenly with a flat brush about $\frac{3}{4}$ in. broad; cover as much as possible with each brushful, as it dries quickly, and, if possible, do not go over the same part twice. The enamel may be had in most cycle warehouses; bottle and brush, 1s. If you mean stone enamelling, you had better give it up, as the apparatus would cost you about £10, not to speak of considerable experience.—A. S. P.

## III.—QUESTION SUBMITTED TO CORRESPONDENTS.

**Hoop Rollers.**—A. L. (*London, W.C.*) would be obliged if some reader would give sketches and instructions to make rollers (about 12 in. long) suitable for bending hoops of tin or thin plate iron.

## IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**Violin Making.**—NO NAME (*Manchester*) writes, in reply to J. E. (*Chatham*) (see page 814, Vol. II.):—"For the *wood* required, get the best well-seasoned log pine and sycamore from any respectable dealer. All the *tools* required may be procured of George Buck, 242, Tottenham Court Road, London, W. For the *varnish*, he will get a good violin varnish by applying to James Whitelaw, chemist, 496, St. George's Road, Glasgow. Follow religiously the articles on 'How to Make a Violin,' which began in WORK, No. 105."

**Browning Gun Barrels.**—P. J. R. B. writes, in reply to C. B. F. (see page 734, Vol. II.):—"Try the following: Wet a rag with antimony chloride, dip it in olive-oil, and rub the barrel with it. In about forty-eight hours it will be covered with a kind of rust. Brush it with a scratch-brush, and polish with a little oil."

**Hand-Power Sawing Machine.**—M. (*Bishop Auckland*) writes, in reply to S. P. (*Penarth*) (see page 782, Vol. II.):—"You can get a hand-power saw bench, with iron frame and table, 6 ft. by 2 ft., from Messrs. J. Carter & Co., New Bailey Street, Manchester, for £10 10s., to cut up to 3 in. thick; they also supply saw spindles, etc. If you write to them, they will most likely supply you with what you require."

## V.—BRIEF ACKNOWLEDGMENTS.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—W. H. Y. (*Battersea, S.W.*); G. G. (*Portsmouth*); C. S. (*London, N.W.*); DERNAX; LEGHORN; ANXIOUS (*Shepherd's Bush*); F. W. M. (*Clerkenwell*); E. S. (*Liverpool*); H. A. K. (*Bedale*); MOTOR; W. B. (*Longton*); C. B. (*London, E.C.*); B. A. W (*Croydon*); CLARIONETTE PLAYER; G. J. F. (*Chiswick*); J. B.; BIRD FANCIER; J. D. (*Poplar, E.*); BOWTON LAD; E. G. (*London, N.*); F. F. (*Leeds*); A. R. (*Blairgowrie*); A. J. T. LE G. (*Guernsey*); A. E. (*Leeds*); N. M. (*Sheffield*); ENGINEER; J. J. W. (*Hartlepool*); J. W. M. (*Ashton-under-Lyne*); F. P. (*Leeds*); J. C. (*Halifax*); A READER; J. B. (*Durham*); T. H. (*Stafford*); G. A. (*Edinburgh*); H. R. P.; H. S. P. (*Nottingham*); READER; S. S. (*Salford*); I. H. T. (*London, S.E.*); W. B. (*U.S.A.*); F. W. M. (*Preston*); N. N. (*Lancaster*); J. W. M. (*Duffield*); J. S. O. (*Weston-Super-Mare*); ARSENAL; PRETORIA; W. I. (*Lawrencekirk*); J. N. (*Cork*); T. R. B. (*Wandsworth*); SINE CERA.

## Trade Note.

THE Second Annual Holborn Industrial Exhibition, 1891, will be held in the Holborn Town Hall and adjoining buildings, on April 29th, 30th, and May 1st, 1891.

# MASONS' WORK.

BY MUNIO.

ANCIENT MASONRY—COMPONENT PARTS OF FIVE ORDERS OF ARCHITECTURE—BASE—SHAFT—CAPITAL—ENTABLATURE—STYLOBATE—PEDIMENT—GREEK AND ROMAN MOULDINGS—BYZANTINE AND ROMANESQUE STYLES—MOORISH STYLE—ANGLO-SAXON—NORMAN—EARLY ENGLISH—DECORATED—PERPENDICULAR—DEBASED—GOTHIC—VARIOUS STONES USED IN MASONRY—WEIGHT AND CRUSHING STRESS OF STONES.

**Historical Styles and Stones in Masonry.**—Masons' work is the art of dressing or cutting stones, and of setting or fixing them together in masses to form various kinds of buildings.

The art must have attained to great perfection at a very early period, as evidenced by the remains of cities, temples, etc., built by the ancient Egyptians, Assyrians, Persians, and other nations of antiquity.

The masonry of these nations was characterised more by gigantic proportions and profuse decoration than by what we term elegance of design. Immense blocks of stone were used. The obelisk now standing on the Thames Embankment, and known as Cleopatra's Needle, is an Egyptian stone.

The Greeks passed from these gigantic forms, and built their temples with great elegance and dignity. We are indebted to them for three of what are now known as the five orders of architecture—the Doric, the Ionic, and the Corinthian.

The following terms are used to denote the component parts of the five orders:—The lower part of a column is the base, the middle part the shaft, and the upper or ornamental part the capital. The entablature is the horizontal portion resting on the top of a range of columns. Its lowest portion is called the architrave, the middle portion the frieze, and the upper or projecting portion the cornice. The lower portion of a base or pedestal of a column is called the plinth, the middle portion the die, and the upper portion the surbase.

The stylobate is either a platform with steps, or a continuous pedestal supporting a range of columns. A pilaster is half a column attached to a wall, and is sometimes rectangular.

A pediment is a triangular gable over a range of columns, with a cornice; the portion under the cornice is called the tympanum.

The mouldings used by the Greeks are shown in Fig. 1. A is the fillet, B the astragal or bead, C the cyma-recta, D the cyma-reversa or ogee, E the echinus or ovolo, F the cavetto or hollow, G the scotia, H the torus.

The Greeks called their random walling opus incertum; walls formed in regular courses were called isodomum; and walls faced with regular courses, but filled with rubble, were called emplectum. They also used a kind of walling called reticulatum, formed with square stones laid diagonally.

The Romans absorbed the three Greek orders, and added two more—the Tuscan and Composite. The Roman mouldings are shown in Fig. 2, and are named the same as the Greek. The Romans used courses of thin tiles in some of their walls, and in others the stones were laid in a sloping form, called herring-bone work (Fig. 3). The Romans were the first who made use of the arch to any extent; as, although arches have been found at Nineveh and Thebes, these nations did not make much use of it in construction—they usually covered their openings with large stones.

A curious dome-shaped building was found at Mycenæ, in Greece, in which the stones forming the arch have level beds, the ends being projected, and cut to the curve on the under side. It is most probable that we are indebted to the Romans for the introduction into this country of what may be termed scientific masonry.

After the time of Hadrian, the art began to decline among the Romans. When the Empire was divided, the art which was practised at Constantinople was called the Byzantine style, while that practised in the

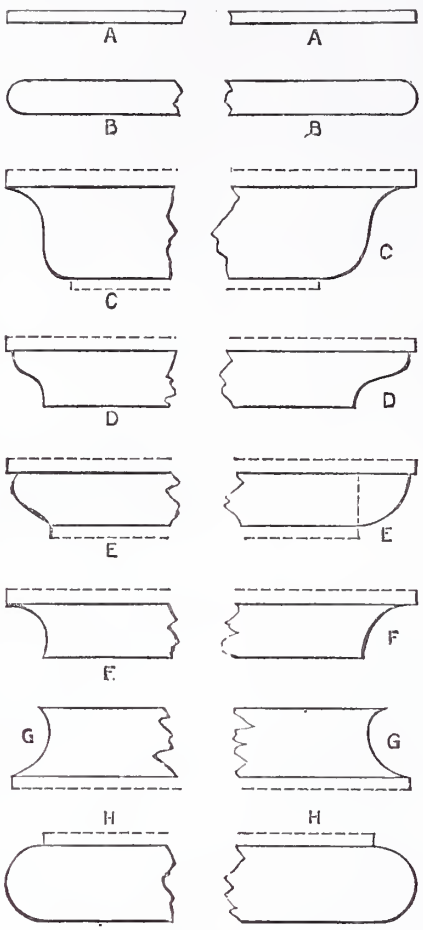

Fig. 1.—Greek Mouldings.

Fig. 2.—Roman Mouldings.

Western Empire was called the Romanesque style.

The Moorish style was that adopted in Spain by the Moors and Saracens. It is known by the peculiar shape of the arch (Fig. 4), by the slender spires or minarets, and by the flowery decoration termed arabesque work.

After the Romans had left this country, and it had been subdued by the Saxons, the style of building which prevailed from the close of the sixth to the middle of the eleventh century was called the Anglo-Saxon style. The semicircular and triangular-headed arches were used, also the peculiar arrangement at the quoins called "long and short work"; the windows and doorways were very low and narrow, and the walls very thick (see Fig. 5).

From the middle of the eleventh to the latter part of the twelfth century, the Norman style prevailed. This is known by the massive pillars and semicircular arches. The doorways were large, and deeply recessed, the arches in the latter period being carved with zigzag and other mouldings (Fig. 6).

Succeeding this style, and extending to the end of the thirteenth century, was the Early English style. This is known by the pointed arch. The piers were formed of numerous slender shafts clustered together, the capitals being carved with foliage. The windows were arched with pointed arches, single ones being termed "lancets." Sometimes three or more were grouped together, gradually rising to the centre. The doorways had moulded arches with a projecting hood mould or dripstone (Fig. 7).

At the end of the thirteenth century, by a gradual and imperceptible progression, the Early English merged into the Decorated style, which existed to the end of the fourteenth century. In this style a greater profusion of ornament was introduced. The windows were large, and divided by slender shafts of stone called "mullions," which in the heads were formed into geometrical or flowing figures called "tracery." The doorways were more ornamented, and pediments and pinnacles with projecting ornaments called "crockets" were used. It is generally considered to be the most beautiful style (Fig. 8).

During the fifteenth century a more elaborate style, called the Perpendicular style, prevailed. The windows were large, and the geometrical tracery was superseded by vertical mullions in the heads. The doorways were covered with low, pointed arches, with a square hood moulding over them. The walls, both on the interior and exterior, were covered with panelling in stone. Elaborate roofs of what is termed "fan vaulting" were used, as at Henry VII.'s Chapel, Westminster, and King's College, Cambridge (Fig. 9). During the latter period of this style, the Elizabethan or Tudor style and the Jacobean style were used in domestic buildings.

Succeeding this was the Debased style, which existed till the beginning of the seventeenth century. This style shows a gradual decline, and was much inferior to those preceding it. At the beginning of the seventeenth century pointed architecture appears to have died out, and was replaced by Italian or classical architecture, as practised by Sir Christopher Wren and others.

The term "Gothic" was applied about the end of the seventeenth century to the mediæval architecture as a term of contempt, by Wren and others.

In the early part of the present century, what is known as the Gothic revival set in, since which time some excellent works in masonry have been executed.

**Stones Used in Masonry.**—The stones used by masons are the freestones, which are obtained from the coal measures in various parts of the country. These stones vary in colour from nearly white to dark brown; in texture from the finest and close-grained to very coarse or open-grained. Some are very soft, but harden by exposure, while others are very hard when quarried. Some are laminated, and are made into landings, flags, etc.; while in others the beds are hardly distinguishable. The following are some of the principal quarries:—Craigleith, near Edinburgh; Prudhoe and Benton, in Northumberland; Pensher and Dunhouse, in Durham; Park Spring and Bramley Fall, in Yorkshire; Hollington, in Derbyshire; Mansfield, in Notts; Forest of Dean and Painswick, in Gloucestershire; Doulting in Somersetshire, etc.

Stones from the Lias formation are

quarried near Whitby and other parts of Yorkshire.

Limestones are quarried at Ham Hill, Chilmark in Wilts, and Barnack. Magnesian limestones are quarried at Park Nook, Roach Abbey, and Bolsover. The new red sandstone is quarried at the Minera quarries in Denbighshire; the old red sandstone in Cumberland and Westmoreland.

From the upper Oolites are quarried Portland and Purbeck stone. There are two kinds of Portland stone—the brown, which is a weather stone, and the white, which is only suitable for interior work. The Ketton, Ancaster, Clipsham, and Casterton stones are also from the same formation.

From the lower Oolite is obtained the Bath stone. The numerous quarries of this stone are now worked by one company, called the Bath Stone Firms. There are eight different varieties of this stone: the Corsham Down, used for sculpture and mouldings; Box Ground, for exterior work of all kinds; Farleigh Down, for partition walls and face work; Corngrit, suitable for weight-bearing purposes, as columns, also for landings and staircases. Stoke Ground, Winsley Ground, Westwood Ground, and Bethel, are suitable for general purposes not too much exposed, and for interior use.

Caen stone is imported from Normandy for interior use, but it is now nearly superseded by Bath stone.

Granite is obtained from Scotland, Cumberland, Wales, Devonshire, Cornwall, etc.

Kentish rag is a limestone, and is obtained from the Greensand.

A basaltic stone of blue colour is used in Cumberland and Westmoreland for walling, called "ragstone."

Freestone is generally composed of siliceous grains or quartz, cemented together by siliceous, argillaceous, or calcareous matter.

Limestones are composed of carbonates of lime and magnesia, mixed with silica and alumina.

Oolites are composed of oviform bodies, cemented by calcareous matter of various kinds. The granites are composed of quartz, felspar, and mica in various proportions.

The selection of stones for masons' work requires great care and consideration. They should be able to resist the action of a smoky atmosphere, of moisture, wind, rain, and frost. Stones used in the vicinity of where they are quarried often stand the weather better than when used in a large town.

It has been found, by experiment, that stones which have the greatest specific gravity possess the greatest cohesive strength, absorb the least quantity of water, and disintegrate the least by the action of the weather.

Freestones absorb less water, but disintegrate more than magnesian limestones.

The stones should always (except in certain cases) be set on their natural or quarry bed. Some stones also require to lay for a certain time to "weather" before being used, while others may be used direct from the quarry.

The weight of a cubic foot of freestone is from 130 lbs. to 160 lbs., and its crushing stress from 4,000 lbs. to 8,000 lbs. on the square inch. Portland stone weighs 147 lbs. per cubic foot, and its crushing stress is 3,200 lbs. per square inch. Limestone weighs 170 lbs. to 180 lbs. per cubic foot, and its crushing stress is from 3,000 lbs. to 8,000 lbs. per square inch. Bath stone weighs 123 lbs. per cubic foot, and its crushing stress is from 1,800 lbs. to 2,000 lbs. per square inch. Granite weighs 160 lbs. to 170 lbs. per cubic foot, and its crushing stress is from 5,000 lbs. to 12,000 lbs per square inch.

In some districts flints are used for walling. They are generally walled in frames fixed to the thickness of the wall, the angles being formed with stone or bricks; they are sometimes walled rough and plastered on the face, and sometimes split, squared, and jointed.

## THE SAFETY BICYCLE: ITS PRACTICAL CONSTRUCTION, ETC.

BY A. S. P.

Position of Rider in Relation to Handle Bar and Pedal Shaft—Steering—Relative Position of Saddle, Handles, and Pedal Shaft—Steering Line in Relation to Forks—Position of Saddle—Double Adjustment of Handle Bar—Pneumatic Tyres—Cushion Tyres.

There is great divergence of opinion among cyclists with regard to the proper position of the grip handles in relation to the saddle, and the position of both in relation to the pedal shaft. Controversial letters are continually cropping up in the cycling journals on this vexed question. If these wranglers would consider for a moment that what suits one does not suit another, they would speedily set the matter at rest. Build and adjust two machines exactly alike in every particular, and mount two riders of the same height and length of limb; as like as not, they will disagree as to the adjustment, simply because the two men are not built alike in every particular. The two men do not walk alike, neither can they be expected to ride alike, and each must adjust the machine (if it is capable of adjustment) to suit himself.

The forward point, or nose of the saddle, is usually the point from which all the positions are taken. Now, in the case of an ordinary bicycle the nose of the saddle is from 2 in. to 3 in. behind a line drawn through the grip handles; then the axle, with its cranks, may be 2 in. in advance of this line through the handles; consequently, the axle to be turned by the feet is from 4 in. to 5 in. in advance of the nose of the saddle. Now, this condition of things suits the majority of riders of the ordinary, but not all. Some would have their pedals vertically under the middle of their saddles, which would be some 9 in. behind the adjustment given above, and, of course, they cannot get it on an ordinary. They may get it on a "Facile," which is worked by levers projecting backwards; but it cannot be called an ordinary—it is a cross between the ordinary and the equal-wheeled safety.

Now, if a certain adjustment of saddle and handles in relation to the wheel centre in an ordinary is found to be good by the majority of riders, there is no reason why the same positions should not be good in a safety; but I have never yet seen a safety so adjusted. The saddle may be placed well enough in relation to the pedal shaft, but the grip handles, instead of being placed 2 in. in advance of the saddle nose, are from 8 in. to 12 in. in advance; consequently, the rider has to stoop forward in order to grasp his handles.

The leisurely rider of the ordinary sits bolt upright in his saddle, with his arms down by his sides, and grasping his handles comfortably and naturally, on a line passing across at the angle of his trunk with his legs.

The safety rider is debarred this easy, natural position, and sits—or rather, lies—with his back arched, as if he were searching for something over his front wheel. Natural bicycle riding should be assimilated to natural walking. Let anyone try how far he will walk comfortably leaning forward at an angle of 45 degrees.

Most safeties are constructed so that the nose of the saddle will touch a line rising vertically from the centre of the driving spindle, or bottom bracket, and the saddle and spring, being mounted on an L-pin, are capable of being adjusted several inches backwards or forwards. Now, suppose the saddle is as far forward as it will come, the rider mounts, and finds it is all right in relation to the grip handles, but it is too far forward in relation to his pedals. He sets the saddle back 3 in., and finds a great improvement in relation to his pedals. But what is the result in relation to the grip handles? Simply that he is 3 in. further away from them, and has no means of bringing them back, for no safety, so far as I am aware, has the means of adjusting the handle bar horizontally; the only adjustment being vertical, or rather in the direction of the steering post. Now this is where the difficulty of a careful adjustment all round exists in the safety, and until makers remedy this, the machine cannot be said to have arrived at what may be called perfection. To adjust the handle bar horizontally is by no means a difficulty, as I will have occasion to show by diagram a little further on.

Another vexed question is the steering of safeties. The ordinary may be steered by the feet alone, because the feet have control over the steering wheel; but in the safety the feet have no control over the steering wheel whatever. The safety is the most tricky machine of any to steer, being constantly liable to wobble; very few racers even can steer without wobbling in a manner never seen on an ordinary. But all safeties are not tricky alike, any more than all row boats are not crank alike, and this is by reason of their build. In the case of the safety, the set of the front fork and steering post have much to do with the steering, and when these are skilfully set, the difficulty of steering is much reduced, and riders with much practice can steer some makes of machines for considerable distances without touching the handle bar.

Accompanying this paper is a line diagram, intended to show the relative position of the saddle with handles and pedal shaft. It will also be a clear guide in making a full-size drawing of the machine, securing, as it will, the relative positions here indicated. A, A, Fig. 2, are two 30 in. wheels; their distance apart, or the space between their runs, is 12 in. In this space is the pedal shaft, B, 3 in. clear of the rear rim, and 12 in. above the ground line. Now, taking the fore, or steering, part of the machine, we draw the line C D, which is a vertical line, from the centre of the wheel to the ground line, the wheel having contact with the road at the point D. Now from the centre of the rear wheel we draw a line E F, and 4 in. above the periphery of the front wheel, at E. Next we draw a line at right angles to E F from C, passing through E; this latter will be the steering line if the forks are straight. Three inches further back is another line, G H, parallel to E C. This is the steering line if the forks are curved, and the amount of curve 3 in.; so that this diagram serves for

either straight or curved forks. It will be observed that the straight fork machine will have a backbone or frame that is 3in. longer than the other, with curved forks.

Now I have to call particular attention to the steering properties of these two forms of forks. It will be observed that the line of the curved fork, G H, falls on the ground line in advance of the vertical line C D, and that the line of the straight fork, C E, prolonged to J, falls in advance of H. H is $4\frac{1}{2}$ in. in advance of D; and J in advance of H 3 in., or $7\frac{1}{2}$ in. in advance of D. The point of resistance being at D, the machine will steer better if made with straight forks, the distance between the point of resistance and the line centres being greater by 3 in. than if built with curved forks.

Now, with regard to the position of the saddle, it will be seen that in the diagram the nose of the saddle touches a vertical line rising from the pedal axle centre. For a rider with a 32 in. leg, the saddle would be 36 in. high. The L-pin should have each arm 6 in. long, and the vertical arm being placed 3 in. behind the vertical line rising from B, the saddle would thus have a travel for adjustment of from 5 in. to 6 in. The nose of the saddle at its forward limit would be 3 in. in advance of the vertical line, and set back to its limit, would be about 3 in. behind said line, which adjustment would be found ample for all riders, unless those who, if they cannot find a fault, will make one. Of course, the saddle has the usual vertical adjustment, to suit different lengths of leg. The position of the handles is here shown 3 in. higher than the saddle, and their rear ends are brought back to a line with the saddle nose. This is about as they would be in an ordinary. The rider could sit upright, and manipulate the steering with grace and freedom, whereas he is usually condemned to sit with arched back and twisted neck, in anything but a graceful position, unless, perhaps, in a race, when it is "sit as you please."

Now, it will be noticed that while the saddle has both vertical and horizontal adjustments, the handle bar has adjustment in one direction only—that is, in the direction of the line G H. Makers should set about giving a double adjustment to the handle bar, when they would find the improvement much appreciated.

The diagram (Fig. 3) will show how I propose effecting this desirable end. The steering tube remains unaltered, but the part usually affixed to the handle bar is detached from it, and has, on its upper end, a boss, which is a steel casting made from a pattern. The tube *b* is brazed to this casting. This casting, *d*, has a hole through it to receive the T-piece, *c*, of the handle bar; this T-piece is $\frac{7}{8}$ in. thick, same as the tube *b*, which slides in the steering tube *a*. The hole through *d* is $1\frac{1}{2}$ in. long, and the part *c* is 6 in. long, so that it is capable of an adjustment of $4\frac{1}{2}$ in. The handle bar, with its T-piece, is fixed by a set screw through the side of *d*, similar to that fixing *b* in the steering tube. The casting *d* is made so that the hole for the T-piece will have an angle, in relation to the part *b*, the same as the angle of steering post or the line G H in Fig. 2; so that the handle bar, with its T-piece, will be level, as shown by the line in Fig. 2, so that in adjusting the handles horizontally the height will not be altered.

This double adjustment of the handle bar involves some alterations of the brake work, but that is a matter that is easily overcome by the clever mechanic.

By a reference to the machine illustrated in the first of these papers, it will be noticed that the handle bar has not this horizontal adjustment. I have shown it here because I consider it a desirable improvement. It is not a patent; and the mechanic who elects to build his own safety is free to adopt it in preference to the usual pattern, as in Fig. 1 (page 33). The same may be said with regard to the two styles of steering forks mentioned in this paper. The illustrated machine shows curved forks, and the line G H is the centre of said forks (see Fig. 2). So the mechanic, whether he chooses curved or straight forks, will find this diagram (Fig. 2) equally serviceable. In following papers, however, wherein the practical construction of the machine will be described, we will hold strictly by the pattern illustrated (Fig. 1), and let those who choose adopt any suggested improvement upon it.

It will be further noticed that the machine illustrated has the ordinary solid tyres, notwithstanding the present rage for pneumatic and cushion tyres. To believe the advocates of, and especially the dealers in, these tyres, one would imagine that a solid tyred machine would be unsaleable immediately.

The pneumatic tyre is made from thin rubber, and filled with compressed air. When blown up, it may be from 2 in. to $2\frac{1}{2}$ in. in diameter, and is certainly not elegant in appearance. It is, without doubt, better than the solid tyre for comfort and easy running, but it is so liable to accident that I cannot but think it will not hold the field for long. Cushion tyres are made from 1 in. to $1\frac{1}{2}$ in. diameter. They have a hole cored out throughout their whole length. This lightens them, and gives them greater elasticity. They are said to be a great improvement over the solid tyre. Personally, I have not tried them, and cannot speak with confidence of their advantages or otherwise. They have, at any rate, caused a revolution in the making of the materials for bicycle construction, as special rims have got to be made for them, wider fork crowns, and flatter and broader mud-guards. The brake spoon has also to be carefully made and adjusted, else it will cut the tyre, which is simply a hollow tube. They have to be made of the best rubber; hence the price is high, and a deterrent to those with a limited purse.

The cushion tyre may hold its own alongside of the solid, but I do not think it is

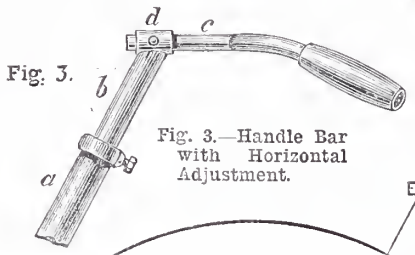

Fig. 3.—Handle Bar with Horizontal Adjustment.

Fig. 2.—Line Diagram showing Handle Bar and Pedal Shaft and Steering Line, with Straight and Curved Forks.

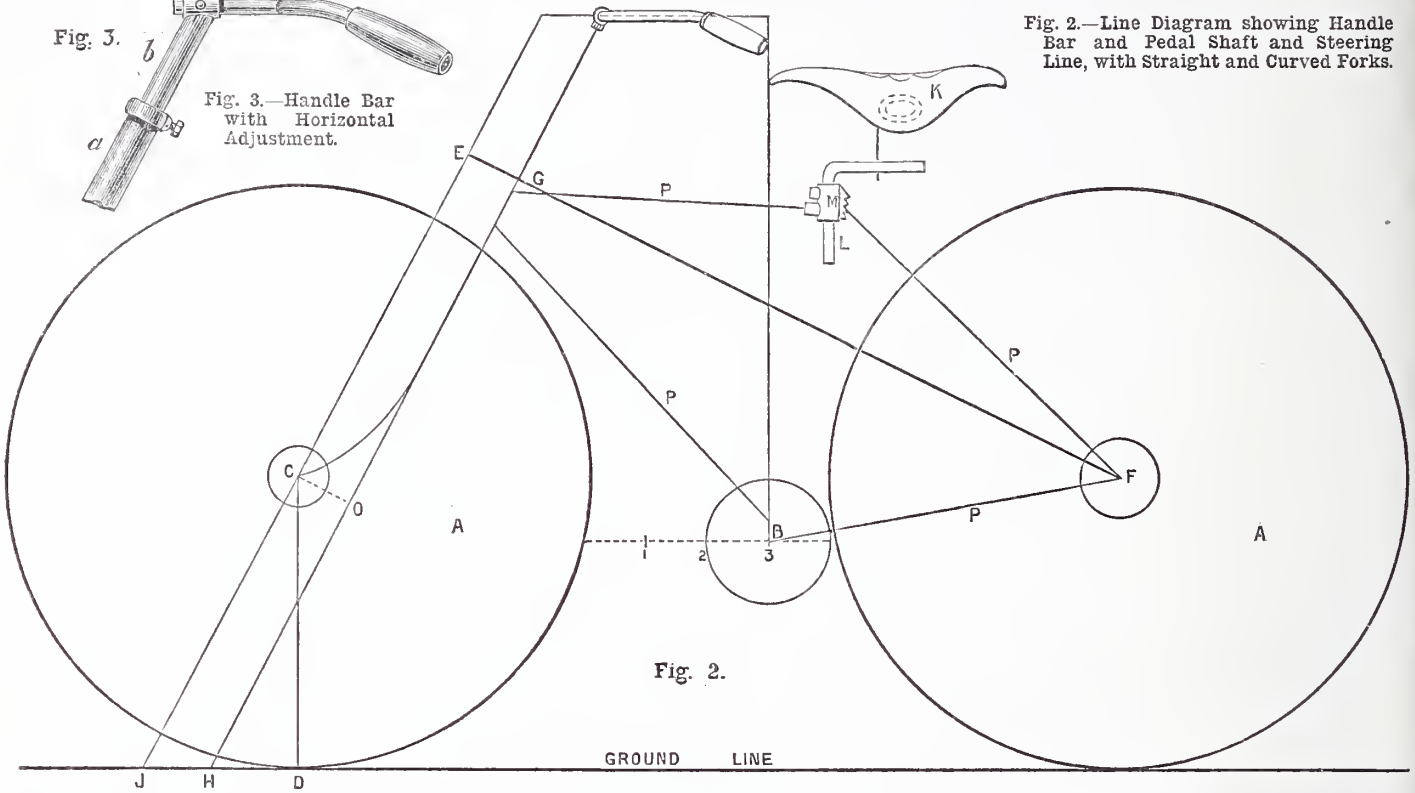

Fig. 2.

likely to supersede it, as a first-class safety, with, say, ⅞ in. solid tyres of best rubber, is about as good a machine as anybody could desire, and much less likely to get damaged and rendered unserviceable when, perhaps, hundreds of miles from home.

My next paper will deal with the materials required for the bicycle, such as stampings, castings, and patterns for castings, tubes, forks, etc., and where best to procure them, with their prices, according to present lists.

## EAR-RINGS AND OTHER ORNAMENTS FOR THE EAR.

### PRINCIPALLY WITH REFERENCE TO THEIR MODES OF ATTACHMENT.

BY H. S. GOLDSMITH.

EAR-WIRES OR SLEEPERS—ANCIENT EAR-WIRES—EAR-RING HOOKS—HOOKS AND CATCHES WITH AND WITHOUT JOINTS.

*Ear-Wires or Sleepers.*—These are the first and simplest form of ear-rings now in use. They are usually made of plain round or facetted—that is, lapped—wire. Fig. 10 B shows the details of the way they are made, although Fig. 10 A is about their usual size.

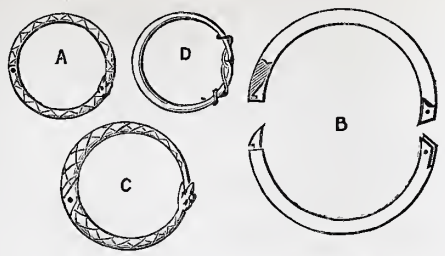

Fig. 10.—Ear-Wires—A, Ear-Wire or Sleeper, ordinary size; B, Details of same, enlarged; C, An improved shape of same in form of Serpent; D, Antique way of making an Ear-Wire.

In these the hardness of the gold itself acts as the spring to keep the catch in its place, and as a rule we find that they are very well and skilfully made, particularly when one considers the very low price they are sold at.

Fig. 10 C is exactly the same sort of thing, but here a more ornamental shape is given to it, and one that is very suitable too: as all our ornamental forms should be. You will notice that it is a serpent, with its tail in its mouth, and it will be, perhaps, just as well if mention is made of the mechanical advantages this shape puts us in possession of.

First, the head is broader and deeper, therefore stronger, and better suited to take the catch. The catch which is rightly formed out of the tapering tail gives us the chance to make it just as thin as we like to have it, for it has to pass through the ear. Now for the joints, which are generally the weakest part of these "sleepers." What have we to say here? Why, that as the body thickens the part where the joint is, we, of course, get greater strength.

Taken as a whole, Fig. 10 C shows thought, and is an excellent example of obtaining all mechanical requirements in a high degree, combined with the other quality that jewellery should possess: namely, be ornamental.

Our friends the ancients managed this class of ear-ring very easily, and strictly correct from an artistic standpoint: at least, so we are taught, for the very merit the material (fine gold) possesses most of—namely, ductility—is here used, as we shall see.

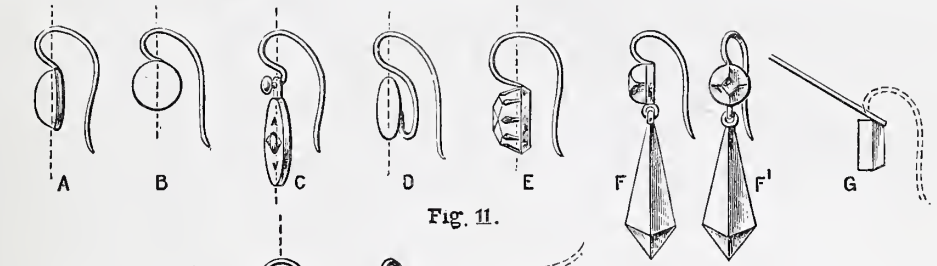

Fig. 11.

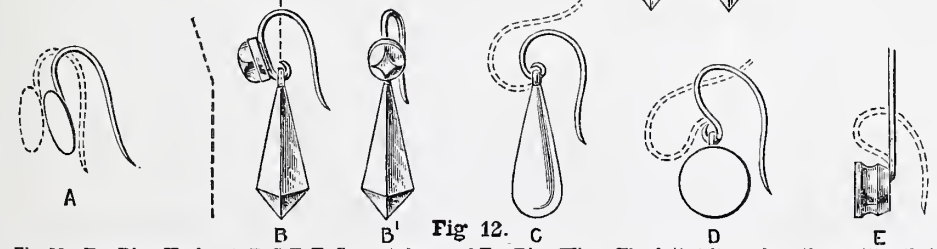

Fig. 12.

Fig. 11.—Ear-Ring Hooks—A, B, C, E, F, Correct shapes of Ear-Ring Wire. The dotted lines show the position that the highest part of Wire is to be, and where a line drawn through the Ear-Ring should come. D, Form of Hook to allow of Attachment of Pendant or Drop—at pleasure; G, Correct direction to solder an Ear-Wire to the Ear-top, to be bent as shown by the dotted lines.

Fig. 12.—Ear-Ring Hooks—A, B, B', Incorrect shapes of Ear-Ring Wire, and the results from such shapes; C, D, Ear-Ring Wires without Stops, liable to turn as shown by dotted lines; E, General way of soldering the Wire to an Ear-top, causing the ungraceful bend, as shown by dotted lines.

They are fashioned thus—a plain piece of wire is taken, and both ends are made to taper. Then some sort of a loop is made out of one end, the other end is passed through the ear, then through the loop, and coiled round itself, as shown in Fig. 10 D.

Of course this is the way to employ fine gold, but it would be a clear case of foolishness were we to attempt to make a pair of jointed sleepers in such soft metal.

Such contrasts as these will, it is to be hoped, give rise in my readers' minds, while they are at work, to just this passing thought: "Am I using a suitable quality or suitable alloy of gold for the result I have to obtain?"

Now we know that different qualities of gold are a necessity in our time, each being suitable for some particular purpose. Therefore, will it not be as well to take note of the modification that different alloys bring about—both for their advantages and defects?

There is but little doubt these will be treated on in WORK some day. But meanwhile, take note of all you can in this way, for "notions" picked up and thought out by one's self are the best, for then they do not get forgotten, as facts that are merely read of generally do.

*Ear-Ring Hooks.*—These, as you see by Fig. 11 A, B, C, D, E, F, G, are simply plain pieces of wire bent up somewhat in a hook-like form. There is some reason in their forms, however, and it is the why and wherefore of the shape that the apprentice should take note of, for on the shape of the wire depends the position of the top of the ear-ring, and may be its safety as well.

Perhaps you have noticed already—or you will after reading this—that nearly all the ear-ring-tops (not ear-studs) worn with and without pendants hang like Fig. 12 A and 12 B—that is, they look downwards, and consequently show a good share of their edges. Now, ear-rings are not generally designed with the idea of showing their edges, but their fronts; and the fronts are made the most ornamental part, in order that they may be seen—at least, that is the way they are fitted into cases; but thanks to the wrong shape of the hook generally, we get the bad result spoken of.

I should often like to take the ear-rings from the ladies' ears and alter them, for it is easy enough. All we have to do to get them to hang properly, is *to make the highest part of the hook in line with the centre or heaviest part of the ear-ring top.*

Dotted lines are in the diagram to show this, but in the workshop we just hang them on a needle-file or a piece of wire, when we see at once if they hang all right.

Even if a pendant is hung from the ear-top, there is not much improvement, for it will hang like Fig. 12 B and B', that

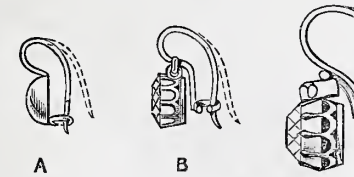

Fig. 13.

Fig. 14.

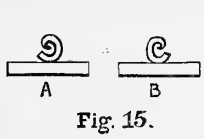

Fig. 15.

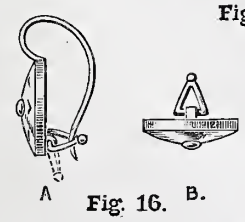

Fig. 16.

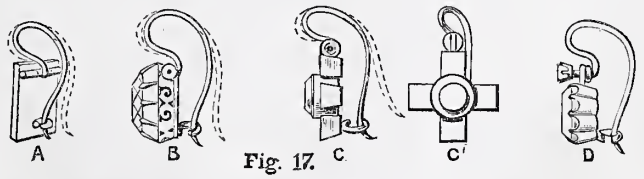

Fig. 17.

Fig. 13.—A, B, C, D, Fixed Ear-Ring Wires and Catches. The dotted lines give the position the Wire should spring to when released from the catch; B, C, Arranged to allow of a Swinging Collet; D, Simple piece of Wire, forming Ear-Ring Hook and Catch, Ring for a Collet to be attached to, and a loop for the attachment of a Pendant, at pleasure. Fig. 14.—Fixed Ear-Ring Hook with fall-down Catch, the dotted line showing position of Catch when raised. Fig. 15.—A, B, Catches as soldered on Ear-Rings, the opening being on different sides. Fig. 16.—A, Fall-down Loop Catch, the dotted line giving its position when released; B, End view or elevation of same. Fig. 17.—A, B, C, C', D, Different forms of Joints for Ear-Ring Hooks; A, B, Ordinary Chenier Joints; C, Side view of Ball Joint; C', Front view of same; D, Joint formed from Rings.

makes the whole affair just about as straight as a dog's hind leg: not at all like Fig. 11 F and F′, as it should be.

All this points to the necessity of hooks like Fig. 11 A, B, C, D, E, F, G, and it does not matter a little bit whether the hook swings like Fig. 11 C or is a fixed one; we *must* obtain the proper result in all cases, and then our work will look straight out at the world, and not hang its head down as though it were ashamed of the workmen that made it.

All the correct forms, Fig. 11, A to G, are taken from those used in the best work, and for proof of that, if in London, take a walk along Bond Street and Regent Street, where you will see in the best shops dozens of examples of what I am talking about—so it is not a new thing I am writing, but is one of the results obtained by experience, and by those who give thought to their work.

Fig. 11 D is one of the forms of hook that allows the pendant to be removed at pleasure.

Hooks like Fig. 12, C and D, should never be made, as they turn upside down, and if they do get in that position the ear-ring will drop out. They can be made all right by soldering something on them (a grain, or shot, or ring), to prevent them turning over, as shown by the dotted lines. Besides this tendency, there is another to guard against, and that is one in which the wire can get fixed in a reversed position: this is just as bad, to say nothing of having the pendant kinked up all askew.

Before finishing with simple wires, there is just a word to be said about soldering them on to the work. It is this: solder it on in the direction it has to take—that is, forward, like Fig. 11 G—then you will get a prettier curve to your wire than you could obtain by bending it sharp forward. This is only one of the little matters, but it tells in giving style to your work. Fig. 12 E is given to show the way that is *not* recommended. You see that the wire does not look as though it belonged to the top, like the other one, but appears to stand away, and besides, it has an ugly bend where the wire starts curving forward.

*Hooks and Catches* (with and without joints).—As these are, of course, for ear-rings, the wires must be of a proper shape, and in addition to that they have fittings similar to a brooch; therefore the same principles that apply to brooches must be considered here—at any rate, as far as they concern the soundness and strength of joint, the position of the catch, and the spring of the tongue. I mean, of course, the spring of the ear-wire. On this point the reader is referred to the papers on Brooches in Nos. 41, 46, 49, and 50, Vol. I. of Work.

Ear-rings with catches are sometimes made without a joint to either hook or catch, and as they are the simplest to look at we will dispose of them first, but they are the most difficult to make act properly.

Fig. 13 A, B, C, D, are all different in shape and arrangement, but all act upon the same principle, which is to get sufficient spring in the wire: first, to hold itself in the catch when it is placed there; second, to spring away far enough on being released from the catch to allow the ear to pass easily between it and the catch. For the latter purpose something over an eighth of an inch is wanted, and to get this distance is no easy matter. The dotted lines show how far the hook should spring back.

Fig. 13 A, being very short, is the most difficult of the four, and after all our hammering and twisting the hook generally has to be bent each time of removal.

Fig. 13 B, C, and D, having longer wires, give better results, and can be made to act fairly well.

For best work, where the cost of an extra hour's work is not of so much consideration, a fall-down catch or jointed hook is much to be preferred.

Before considering these, perhaps a word about Fig. 13 D will not be a waste of space, for out of one piece of wire is ingeniously formed—first, an ear-ring hook; second, a catch to retain it; third, a loop to swing a collet; and fourth, another loop for a pendant or pearl to hang on.

With fall-down catches we get an improvement, inasmuch as the great strain necessary to obtain so much spring is taken away from the wire, and we at once get the necessary space for the ear to pass by simply turning the catch down.

Fig 14 indicates how it is turned down out of the way, and the dotted lines show the position ready for fastening the hook.

The usual C-shape catch is the one most often employed, and on a pair of ear-rings they should be placed with their openings on different sides, like Fig. 15 A and B, the reason for this being that ladies find it easier to fix them from outwards towards the head.

Occasionally another form is used, and this is shown in Fig. 16 A and 16 B—these are the side and front views. This loop-catch is made out of a piece of tubing, which is soldered on to the ear-ring, and out of a piece of wire bent up in the form shown, this wire loop moving as shown by the dotted lines. This form of catch answers all right if the length of the ear-wire is properly adjusted to it. The small grain of gold you see soldered on the top is simply to give the nail something to catch hold of when the catch has to be moved.

In these the ear-wire is made to spring a little, just sufficient to hold in the catch, and that is about all the extra work the ear-ring wire is asked to do in this form of ear-ring, for the first and principal duty of the wire is to hang the ear-ring in the ear.

Now and then an obstinate customer will insist on a catch being added to the lower part of an ear-ring that swings loosely on the top part, and so depriving us of a fixed point for the wire to press against. In such a case we had better use the lyre-shape catch. The shape of this and the way it acts is shown in the paper on Catches of Brooches, and the diagram is Fig. 9 in Vol. I., page 772, of Work. These will not give you the size and thickness of wire, etc.: that you will have to judge for yourself; but they will appear rather weak of necessity, or else you will obtain no spring at all in them.

Hooks soldered on a joint are now in very general use, and there is but little to say about them except to speak about one or two points that have to be attended to:—First, enough action in the joint to allow of sufficient opening at the catch; second, strength of joint, combined with a workman-like neatness of fitting, and all is to be so arranged that there is something to prevent the wire coming too far back, for just as we used a fly-up plate in a brooch as a fixed point from which to obtain resistance, and so to enable us to get a spring in the brooch tongue, so in these we must obtain some corresponding fixed point for our ear-wire to spring from.

It is not a difficult matter, and there is no need to "lie awake o' nights" to think about it, for we generally carry the ear-wire right round the joint until it touches either the back or the inside of the ear-ring.

The simplest way is shown in Fig. 17 A, and you notice that this ear-wire and all the others are bent after the form previously spoken of, but with this slight difference—that it is just far enough away on the upper part to allow of sufficient opening at the other end, near the catch, when the wire is brought forward.

In the grain-collet ear-ring (Fig. 17 B) the joint is let into the collet; this is for neatness and strength.

If the very top of our ear-ring were of such small size as to reduce the length of our joint too much for a fair amount of strength, then we should use another form—most likely Fig. 17 C and C′, or some adaptation of it. It is, as you see, a ball joint, made as the ball joint for brooches are—out of three flat plates. It is narrow, but strong, and forms, when well made, a very neat and compact joint.

Hitherto we have said nothing of ear-rings formed from two ornaments or two settings—in fact, the last three diagrams show the whole of the fittings soldered on to one piece. If we have to swing a collet we must make a mount to carry the catch, something like the lower part of Fig. 13 B and C. In these, although more irregularly arranged, still we find all the same parts that we have in a brooch, but modified to suit the new conditions, and, as previously written, the arrangement of these joints and catches is subject to the same rules as for a brooch.

Yet another way is shown in Fig. 17 D. It is formed out of rings, with a collet or bead in front. The ear-wire plays through the ring soldered on the drop or pendant until it is to be fastened by the catch, when the two rings jamb, and so give the wire the necessary resistance.

These examples will probably suffice, for on these lines surely anybody will be able to devise something suitable for their requirements.

Pages of writing and dozens of diagrams might be given, but they would be but variations on those already given, so we will stop, and in the next paper we will talk about some other kind of fastening.

## A SIMPLE APPLIANCE FOR POLISHING TURNED METAL WORK.

BY OLLA PODRIDA.

The accompanying cuts illustrate a simple appliance whereby a good finish and high polish may be imparted to turned works between the lathe centres. Tapered or curved works, such as handles, pillars, stanchions, etc., can be treated with facility, and slight modifications in the form of the polishing clamps, or "sticks," as they are sometimes technically called, will enable surfaces of more complicated contour to be treated with ease.

These sticks are best made of the softer kinds of wood, such as pine, so as to avoid the danger of scratching or grooving the work which attends the use of harder kinds of wood. Fig. 1 shows a pair of these in profile, as they would appear all ready for use, and, as will readily be understood, adapted for three different sizes of work. Fig. 2 gives a plan of one-half, showing the grooves in which the work revolves, and the feeding channel at the front sides. The method of construction will be obvious, and detail of same unnecessary, further than that the hinge, although it may be made of metal, is best formed out of a strip of leather nailed over the ends, which must be rounded

as shown in sketch. The grooves for receiving the work must not, when closed together, wholly embrace the subject, but must be so arranged as to leave between the sticks a moderate space — sufficient to apply the polishing material. Fig. 3 will show at a glance what is meant by this, and how it is attained by cutting away the adjacent faces after marking, and cutting or boring the holes to form grooves, which, by the way, if not too large in diameter, may readily be accomplished by clamping the two parts together, and sending a sharp centre-bit through to the marks.

The detail of polishing is simple, and as follows:—After the work has been turned

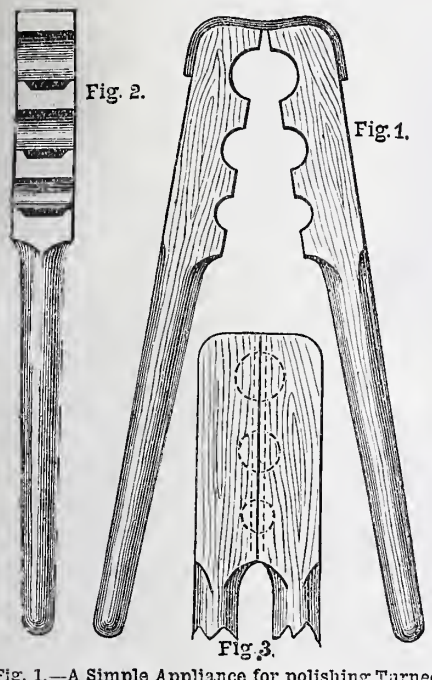

**Fig. 1.—A Simple Appliance for polishing Turned Work, shown in Profile as ready for Use. Fig. 2.—Plan of Half showing Grooves and Feeding Channel. Fig. 3.—Mode of cutting Grooves for receiving Work.**

and, where necessary, smooth-filed, it is revolved at a good speed in the embrace of the sticks, the feeding channel being kept supplied with emery and oil. If a high polish is desired, it is better to use a second pair, lined with leather in the groove, and kept for fine powder only. To facilitate the maintenance of an even pressure on the work, the handles may be tied together with a piece of cord, and the sticks pushed regularly from one end of the work to the other. This, with a little practice, can easily be accomplished by giving a slight angular movement or advance to the handles in the direction required. The waste emery and oil, or drippings, should be carefully saved for future use, and must not be allowed to accumulate amongst the working parts of the lathe.

## AN EASILY-MADE NEST OF PIGEON-HOLES.

BY C. E. MAES.

DESCRIPTION — CAREFULNESS — ARRANGEMENT OF HOLES—THE ORIGINAL MODEL—MATERIAL—TOOLS — SIZE — OUTER CASE — JOINT FOR SHELVES AND PARTITIONS—FORMING GROOVES —FITTING PARTS TOGETHER—SUGGESTIONS FOR ORNAMENTATION.

I SUPPOSE it is not necessary to tell any reader that the pigeon-holes referred to have no connection with Columbarian pursuits. If it is, let me say that the pigeon fancier will not find anything to interest him in this article. By telling him this at the outset he will not be disappointed when he finds, after having read it through, that pigeon-holes—or, to express the thing more correctly in technical parlance, a nest of pigeon-holes—are for keeping letters and other documents in. Of course, there are various kinds of contrivances for this purpose, and on looking at the illustration of the "nest"—strange how the idea of ornithology sticks to this little piece of furniture, is it not?—possibly some experienced wood workers may be inclined to turn up their noses at it. They will find this a more difficult operation than making the pigeon-holes; but if they will be kind enough to remember that a novice at wood working would find this latter equally difficult of accomplishment without directions, they will, if not inclined to welcome these, at least look on them with tolerance.

There is a beginning to everything, and the beginners at WORK must be helped forward as well as the more advanced. This remark, of course, is for the minority—doubtless a small one—of readers who are so unreasonable as to think or wish that their own requirements should be specially catered for in a magazine which caters for all.

Simple though the construction of these pigeon-holes may be, it will yet afford useful exercise to the tyro; and when it is made, no doubt he or some of his friends will be able to find a satisfactory use for it. If he succeeds in making it neatly and well, he may in time to come be able to regard it with pleasure as an early effort.

I may here say that, because it is simple, it will be a mistake for the beginner not to use as much care over its construction as he can. Careless work never achieved anything worth noticing, and the novice is too often discouraged by attempting to make something altogether beyond his powers. Let him proceed slowly and carefully from simple construction to more complicated contrivances, and he will find that his skill increases almost insensibly till, in the no distant future, he finds that he is able to accomplish anything in reason connected with the craft he has taken up, either for a pastime or as a business.

We all know Carlyle's definition of genius, and, without going too closely into it as of general application, there is no doubt that the cleverest and most skilful artisan—I won't call him a genius—is the one who takes the most pains with his work, whether it be great or small. He is, in fact, the one who obeys the injunction, "Whatsoever thy hand findeth to do, do it with thy might"—given, by the way, was it not, by a tradesman or artisan who might be supposed to know what is necessary in the way of good advice to hand as well as head workers?

Now, after these prefatory remarks, given by way of encouragement to beginners, and perhaps a little bit by way of apology to more advanced workers, let us see about making the nest.

In its primitive simplicity, it consists of an oblong box with an open front. It has two shelves, with a series of upright divisions, by which means the "pigeon-holes" are formed.

As the English alphabet consists of twenty-six letters, we may reasonably suppose that a nest containing about that number of holes will be the most generally convenient. The illustration shows the rows of holes, but it might as well have been four, or, in fact, any number; but as three into twenty-six won't go—I think that is the way that it was expressed when "we were boys together"—without leaving a hiatus somewhere, we just make three rows of nine holes each, being twenty-seven in all, or one more than the alphabet requires. It will come in handy for some purpose or other, so that we need not object to its existence. Special papers which it is desired to have separate may be kept in it, and, indeed, one or two more holes may be reserved for the same purpose; for it will be an unusual lot of correspondence which has many or an equal number of papers beginning with the same letters of the alphabet. As a suggestion, the X Y Z letters may be put in one pigeon-hole, without much difficulty arising when a particular document is wanted.

However, if the directions for making one set of pigeon-holes can be carried out, the veriest duffer can have no difficulty in making his own arrangement.

Perhaps it may lend additional interest to the nest, which forms the basis of this article, to say that it is in the editorial room of WORK, and that in it are accumulated the letters which are continually arriving for answer in "Shop," as well as others for the consideration of the Editor.

Of course, such a mass of correspondence requires a much larger nest than would be required for private purposes, and I have therefore taken the liberty of altering the dimensions of the original to those which are more likely to be generally useful. Those who do not like them can alter them to suit their own wishes.

What kind of wood are they made of? This is naturally a question which the beginner will ask, and very probably he takes sufficient interest in WORK, and all that pertains thereto, to wish to make his like the original one referred to, or, at any rate, of similar material. Now, from what I can gather, an editor's apartment is popularly supposed to be fitted up in a style of luxury and with a beauty of appointment which the humble reader cannot hope to aspire to; and of course, on this supposition, the editorial pigeon-holes are made of—well, let us say a choice and costly wood. I fancy I hear some one with the bump of curiosity largely developed say, "Why can't he tell us exactly what it is?" Well, my brethren—or, if you like it better, my fellow admirers of WORK—the reason is just this: On one occasion, shortly before I was asked to write on a particular subject, I was taught to be cautious. I was not sufficiently so when I got pen in hand and paper before me. That MS. was not published, and I got a "wigging" from the presiding genius. I do not wish to incur the mildest of mild rebukes from "our" Editor, so it must be sufficient to say that pine may be used instead of a choicer wood by the novice who essays to make the present pigeon-holes.

Although pine is a common wood, there is no reason why it should be bad of its kind. A nice clean piece—by which I mean that it should be free from knots and shakes or cracks—will work up admirably. It should also be dry, and in order to ensure its being so, it may as well be kept in the kitchen or a warm, dry room before it is used. Wood is often seasoned thoroughly, but not be quite so dry as it might be when it is first brought in from the timber yard, where it has very likely been exposed, more or less, to the changeable atmosphere of our climate. Do not, in any case, attempt to

dry it too quickly by the fire, or the results will not be satisfactory, and may possibly necessitate the expenditure of more money at the timber yard.

One of the first points to be decided on is the thickness of the material. The job will look better if the outer case is thicker than the shelves and partitions, but this is not a matter of importance. As very thin wood is not as easy to work up as comparatively thick stuff, we may take it as being about $\frac{3}{8}$ in. thick for all portions. If two thicknesses be decided on, let the case be, say, $\frac{1}{2}$ in. thick. Of course it may be much more, and may be less, if the maker has any wood lying by him that he can use for the purpose. Strength is, however, amply secured by the thickness named, and might be so even if it were less.

The depth from back to front being comparatively unimportant, let us assume that it is just the width of the board from which the job is to be made. As the wood will probably have an irregular edge, it must be set out from the narrowest part, and this, we may assume, will not be less than 9 in.

After the wood is planed smooth, the only tools absolutely necessary will be the square, a bradawl, a screwdriver or hammer (according to screws or plain nails being used), and a chisel of not greater width than the thickness of the wood forming the upright partitions. Even if the tools have to be bought specially, this will not involve a great outlay; it will be less than the cost of making the article, and, as the tools remain for future use, they may be considered, from a pecuniary point of view, a gain, or as representing profit—not in cash, of course, but in stock.

First of all, in making, with the aid of the square cut off two pieces of the board 27 in. long, and two pieces 1 ft. long each. These will form the top, bottom, and ends of case, and will be nailed together. The great consideration, of course, must be that opposite pieces are exactly of the same size, and that all the edges are square. If a piece is wider than the one opposite to it, or is wider at the front than at the back, or *vice versâ*, then a good square case is out of the question; for it is an impossibility to make a perfectly rectangular box if all the parts are not regular. With care, there will be no great difficulty in getting them so.

It is suggested that the top and bottom are to be nailed on to the ends, though whether this or the alternative of fastening the ends to the top and bottom be adopted is not a matter of vital importance. Those who can do so may prefer to fasten the parts together with dovetails, but as this presumes the maker to be possessed of more skill than those I am specially writing for, no detailed directions need be given.

The case being ready, the shelves will be cut to fit tightly within the ends. They will, of course, be the same width as the top and bottom, and should be cut with perfectly square corners. When they are cut, do not fasten them in at once, but wait till the partitions are ready and the grooves cut for their reception. The joint for the shelves and the partitions is shown on an enlarged scale in Fig. 2. From this it will be seen that the edge of the partition is sunk in a groove cut for it in the shelf.

This form of construction may not be the strongest possible, but as it is strong enough, nothing more can be required.

The width of the grooves is just enough to allow of the partitions fitting tightly into them, and their depth in proportion to the thickness of the shelves is sufficiently shown in Fig. 2.

To mark and cut these grooves is an easy matter, but it must not be done haphazard. At equal distances from each other, mark out the position for the divisions, either with compasses or by other convenient means, remembering that at the ends of the shelves the spaces must be shorter by half the thickness of the partitions than the others. The reason for this is so obvious that nothing need be said about it.

The places for the partitions being ascertained, with the square draw lines across, representing the width of the grooves; then cut these lines down to a uniform depth with the chisel, cutting downwards, or, guided by a straight-edge, draw it along so that it cuts into the wood. If the cut is not deep enough, it can easily be made so by repeating the operation as the waste wood is removed. This can be managed with the narrow chisel already referred to as one of the necessary tools for making the job with. The cuts at the sides of the grooves allow the wood between them to be removed without disturbing the surfaces of the shelves. The bottom of the grooves need not be made absolutely smooth, as they are not seen when the parts are fitted together, and a finicking amount of finish is not necessary, for the work will be just as strong and substantial without it.

All the grooves being ready, the shelves may be fitted in their places and the upright partitions be forced in. The grooves will hold those between the shelves, while those above the top and below the bottom shelf will be held partly by the grooves and partly by a few nails through the top and bottom. It only remains to fasten thin wood on the back, and our nest of pigeon-holes may be considered complete. It will naturally occur to the user to mark each hole with a letter of the alphabet, according to the documents it is intended to hold, but certain easily effected ornamental details may not so readily suggest themselves without a hint or two.

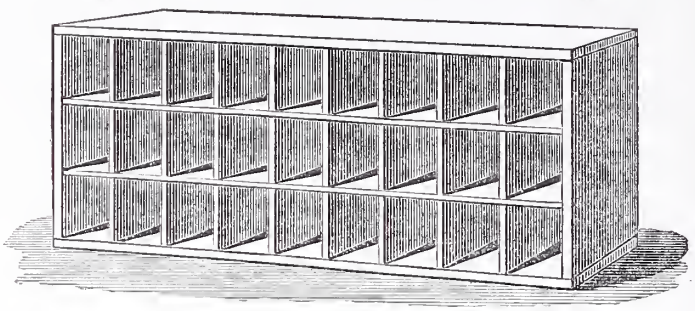

Fig. 1.—Nest of Pigeon-Holes: Plain.

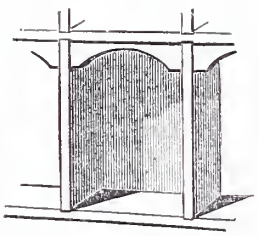

Fig. 3.—Bracket at Top of Pigeon-Holes.

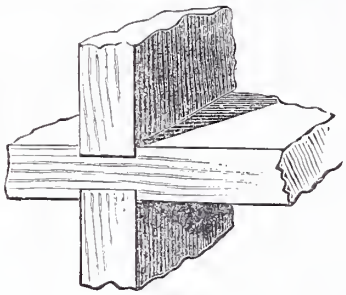

Fig. 2.—Connection of Partitions and Shelves.

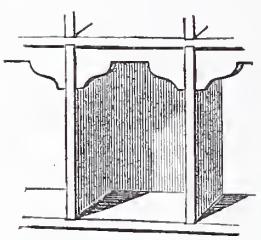

Fig. 4.—Alternative Form of Bracket.

An excellent finish, relieving the stiff, straight lines, may be easily formed by putting thin pieces of wood at the top of each hole. They are decidedly ornamental, and anyone who has a fret saw will have no difficulty in doing what is necessary. By way of suggestion, two appropriately shaped pieces are shown in position in Figs. 3 and 4. The pieces, of course, are fastened by small blocks of wood glued in behind them.

In Fig. 5 is shown a really handsome-looking nest of pigeon-holes, and yet it is virtually the same as the one which has been described.

The ends are thicker, and their front edges are beaded with the "scratch," a tool which has been so fully described in WORK already that further remarks about it would be out of place. The top edge is merely a piece of ordinary pine moulding, such as can be got in any large town from those who supply builders with them. The bottom is thickened up and the appearance of moulding given to it by three pieces of stuff, 1 in. thick and, say, 2 in. wide, being fastened on to the bottom board by means of screws driven through from below.

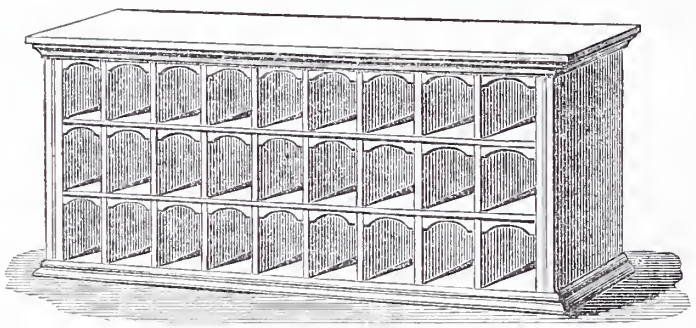

Fig. 5.—Nest of Pigeon-Holes: Ornamented.

The front piece should be the whole length of the job and the end pieces shouldered up behind it, so that they need not be mitred at the corners.

If these end pieces are cut off across the grain of the wood, instead of with it, they will be better; but on a job of this kind attention to this is not of the greatest importance.

The edges can easily be rounded off, as shown, with the plane, and finished with glass-paper.

With the remark that the job, when made, may be stained and polished or painted, according to fancy, these directions and suggestions must be brought to an end.

## HINTS ON MECHANICAL DRAWING FOR TEACHERS.

BY H. A. MILES.

Preparation of Wall Diagrams—Points to be Kept in View—Drawing-Board—Size Recommended — Method of Construction — Testing Accuracy—Arrangement for Taking Continuous Paper without Folding—T-Squares—Instruments—Ruling Pens Unsuitable—How they may be Adapted to Ruling Thick Lines — Most Suitable Breadth for Lines—Parts in Section—Colour *v.* Lines—Drawing Large Circles—Simple Beam Compasses—Shading Circles—Perry's Pen for Letters and Figures—Best Size for Same—Use of Stencil Plates—Inserting Dimensions—Wolff's Chinese Ink — How to Ink in Large Drawings—Cleaning Up—Mechanical Drawings and their Disadvantages—Should be Supplemented by Perspective or Isometrical Pictures.

How often has the reader wanted to make an illustration which has to be looked at from a distance? For example, a banner is required for the Sunday School, a large illuminated text for the walls, or, in the case of either a school or science teacher, a wall diagram is required to illustrate some portion of a lecture.

As a teacher of machine construction and drawing, etc., I have had to prepare a large number of such diagrams for class demonstration, and have at the present time over a hundred illustrations of machine and engine details, all prepared in the way I shall now describe.

To prepare a drawing, every detail of which must be perfectly distinct in the furthest corner of the class-room, requires, of course, a special method of treatment, and experience only can enable the draughtsman to judge what will be the best scale to draw to, so that while every portion shall be easily understood, no part is wastefully large. It is best, in some cases, to treat the very small details separately on a larger scale.

I do not in this paper propose to *teach* anyone mechanical drawing, but merely to explain the various methods by which I have overcome the many little difficulties continually cropping up, and assist others by bringing to their notice some of my own dodges for saving time or labour.

The drawing-board is, of course, the first consideration, and that which I have found best is a pine board 5 ft. by 3 ft., this size taking antiquarian or continuous paper.

It should be constructed as follows : The grain should run lengthways of the board, which should be of ¾ in. even-grained pine, entirely free from knots ; when glued and joined, the boards should be clamped up tight and left till dry—at least twelve hours. Both sides should then be evenly planed, and one edge shot up true and marked. The two ends and the other side may now be trued up from the first, and a final check on its accuracy taken by measuring it across diagonally from corner to corner, when, if both diagonals are equal, the board will be square. This test does not prove that the sides are straight, but the eye run along the edge will detect any inaccuracy. The best surface should be decided upon, and marked. The other must now be grooved with a plough plane at intervals of 3 in. or 4 in., the grooves being ¼ in. wide, and deep enough to leave a thickness of ¼ in. The warping and shrinking properties of the board are now practically reduced to one only ¼ in. thick, and made in widths of 3 in. or 4 in.

At least three battens, for the purpose of strengthening the board, will be required, and two of them must be about 6 in. longer than the narrow width of the board, for a purpose I shall presently explain. One of these must be fastened at each end, and the other in the middle of the board, as shown in Fig. 1. These battens must be fixed in a certain way, or the board will twist.

Each should be screwed in the centre, and all other screws necessary must be placed in longitudinal slots, as shown, thus allowing for expansion and contraction due to atmospheric influences. The board is now completed as far as ordinary work requires, but if continuous paper is to be used, a slight addition, designed by the author, will be required.

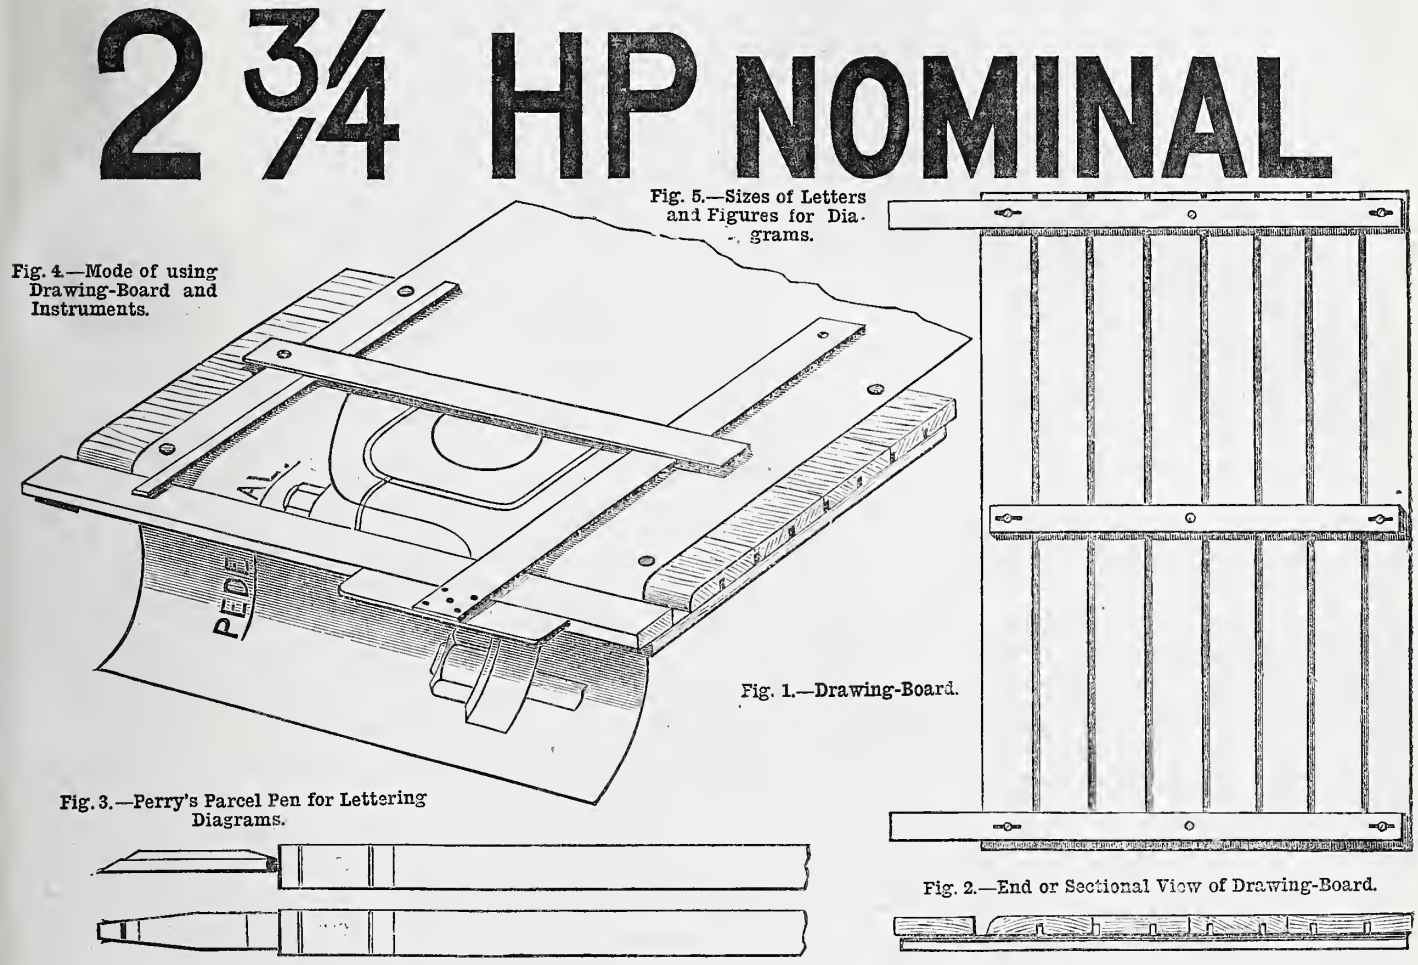

Fig. 5.—Sizes of Letters and Figures for Diagrams.

Fig. 4.—Mode of using Drawing-Board and Instruments.

Fig. 1.—Drawing-Board.

Fig. 3.—Perry's Parcel Pen for Lettering Diagrams.

Fig. 2.—End or Sectional View of Drawing-Board.

Take a strip of close, straight-grained mahogany, 5 ft. long, about 4 in. wide and ¾ in. thick, and plane it up accurately, with the sides perfectly parallel. This piece is now to be screwed to the two end battens in such a way that a gap about ½ in. wide is left between itself and the edge of the board, which is rounded off. The completed part of a drawing on continuous paper may be slipped down this opening, and a fresh surface exposed to the draughtsman, while the T-square always has a guide to work against, and no folds need be made in the paper, as shown in Fig. 4.

T-squares of pear wood are cheapest, and two will be required—one for each way of the board. The blades, which should be screwed to the stock, should be parallel, and not taper, as, owing to the size of the board, it is often necessary, especially when working at night, to use both sides of the blade in order to avoid shadows.

With regard to instruments, the ordinary

ruling pen will be found of but little use, the lines being almost invisible a few feet away, and much labour is entailed by ruling double lines and filling up the intervening space by a brush; while the brush alone is unsatisfactory in every way.

A simple yet wonderfully efficient dodge was thought of by the writer to surmount this difficulty.

A piece of fine linen is folded so as to present a nice blunt point, and is then placed between the jaws of the ruling pen, and the screw tightened, the waste material on either side being removed by a sharp knife. The pen may be supplied by means of an ordinary writing pen, or itself dipped into the ink direct. The first few strokes will be rather too fine, but the point rapidly widens to the full extent of the opening between the jaws, and a splendidly even line will then be obtained. The ink is held in reserve very effectively, only just sufficient being allowed to pass to the paper. The best thickness of the lines varies from $\frac{1}{100}$ in. for internal details to $\frac{1}{8}$ in. for outlines. Sectional shading may be done with this pen, but a darker wash of colour should be used in preference to lines, as the latter seriously interfere with the clearness of any dimensions which it may afterwards be necessary to insert. The pen joint of the ordinary compass may be treated in a precisely similar manner.

It frequently happens, however, that a circle is required which is too large to be described with these compasses, and the following plan may then be adopted as a cheap substitute for beam compasses—

Take a thin strip of wood, about $\frac{5}{8}$ in. by $\frac{1}{8}$ in., and fit the compass pen into a hole at one end. A pin passed through a fine hole and driven a short distance into the board will form the centre, and the circle can then be readily described, the bar being left long enough to accommodate itself to various-sized circles.

By the way, while speaking of circles, it sometimes happens that in a shaded drawing one side of a circle is required to be thicker than the other, and it is a very difficult operation to successfully accomplish. If, however, the centre be very slightly shifted towards the side in shadow, and the half circle again struck with the same radius, the effect will be perfect, the line gradually increasing in thickness, and as gradually merging again into the ordinary size.

For lettering, the best pen is Perry's parcel pen, shown in Fig. 3. It can be obtained in several widths, and engrossing or block lettering can be very effectively performed by its use. Some little practice is necessary, but if the pen be pointed outwards, as if writing with a "J" pen, very little difficulty will be experienced.

The most useful size for letters and figures is $\frac{3}{4}$ in. for important words and $\frac{5}{8}$ in. for ordinary lettering, such as names of engine or machine details. Figures should be $\frac{7}{8}$ in. for whole numbers, and $\frac{5}{8}$ in. for fractions.

For economy of space fractions are best inserted thus, $\frac{7}{8}$ in., rather than $\frac{7}{8}$ in.

Stencil plates are very useful, but require to be specially cut, as the ordinary Roman letters are unsuitable. The form most useful are oblong block letters, a specimen of which, with figures, is shown full size in Fig. 5.

All lettering and dimensions should, however, be left till the very last, after all colouring is perfectly dry.

The best ink to use is Wolff's liquid Chinese ink, which is of a dense black, and for ordinary work will bear 50% of water being added to it. This ink is especially suitable if the drawing is to be coloured, as when once dried, it is impossible to wash it up, even after prolonged saturation. For inking in, a flat ruler with a bevelled edge will be necessary, also a couple of strips of wood, about $\frac{5}{8}$ in. by $\frac{1}{8}$ in.; these and the straight-edge may be about 3 ft. long. The method of using them will appear further on.

It will now, perhaps, be advisable to follow the course of a drawing through all its stages before colouring is touched upon.

The board being placed at a height suitable to the draughtsman, the paper is placed on it, and fastened with a drawing-pin at each corner, first setting the paper square with the sides of the board. The usual method of procedure is then followed with regard to centre lines, etc., etc., until the drawing is completed in pencil.

All circles or arcs of circles must now be inked in, the pen being filled up as before described. The two thin strips of wood may now be placed across the drawing so as not to rest on any wet lines, and used as supports for the straight-edge. These strips may be shifted as necessity occurs, and the entire drawing inked in without any delays, while certain portions dry.

It will be found best to do all the thin lines first, and as the pen point widens with use, to insert the broader outlines. All lines in one direction should be done at once, as far as possible. The strips may then be placed parallel with them, the ruler laid across it, and those in the opposite direction filled in. Dimensions may now be inserted, the dotted lines being done in red, arrow-heads in black, and the whole drawing cleaned up with indiarubber.

If, however, the drawing is to be coloured, the paper must, previous to use, be damped and fastened by its edges to the board, narrow strips of gummed paper being useful for this purpose. Ordinary water colours are suitable, and brushes according to the fancy of the draughtsman.

All colouring should be as light as possible, the parts in section being slightly deeper in tone than the remainder; curved surfaces may be lightly shaded to assist the students in understanding their true shape.

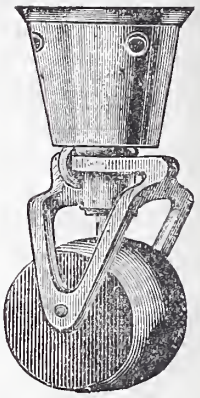
In concluding, the author advises all teachers of mechanical drawings to supplement their plans and elevations by models and perspective or isometrical drawings of the details illustrated; as every first year student experiences the greatest difficulty in understanding the construction of a piece of machinery until he has had a certain amount of practice in reading mechanical drawings. If this method is followed, the results will amply pay for the extra trouble involved.

## OUR GUIDE TO GOOD THINGS.

*** *Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of* WORK *for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of* WORK *without charge, the notices given partake in no way of the nature of advertisements.*

12.—Hart's Cantilever Bowl Castor.

I think all readers of Work will agree with me in condemning the old-fashioned ordinary form of castor—or easter, for both modes of spelling the word are used, and I venture to think the latter preferable—in which the axis on which the wheel of the castor worked went through the ends of a couple of pieces of brass, proceeding from a socket revolving on a pin issuing from the bottom of the cup of the castor; an arrangement which tended to throw the wheel right out of, and away from, the direct line of pressure, passing down the centre of any table leg or chair leg, which was perpendicular to the plane of the floor. It was a weak form of castor, liable, if badly made, to get quickly out of good working order, and many varieties have been introduced which have been, to a greater or less extent, improvements upon it. The latest with which I am acquainted is Hart's Cantilever Bowl Castor, figured in the accompanying illustration, a prospectus of which has been sent me by Mr. A. Marmaduke Hart, Vicarage Park, Plumstead Common, S.E. To judge from the illustration and description it seems to be an excellent form of castor, for the reason mentioned above; but I can say no more than this, as I have received no samples which I might put to a practical test. I append Mr. Hart's description of the castor, and from this and the illustration my readers will have as good means of forming their opinion of the article as I have as yet had.



**Hart's Cantilever Bowl Castor.**

Mr. Hart claims that the Cantilever Bowl Castor is "the most perfect castor for furniture, etc., ever invented, combining all the advantages of all other castors, equal to central action without the disadvantages, cannot get out of order, perfectly noiseless and free in action, no side strain. The principle briefly stated is, that the cradle, or holder, forms an unequal-sided triangle or pyramid, the base being divided into unequal lengths by the central pin, the bowl being at the apex slightly out of the centre. By means of the cantilevers the balance is readjusted, and makes the bowl equal to being in the centre of the castor; also the cantilevers overcome any resistance. The arrangement is so simple that it will be easily understood on reference to the drawing. The principle of construction is a sound one. For chair and couch work it is invaluable, entirely preventing fracture of the wood, straining the legs, or breaking out of the screws, which is constantly resulting from excessive leverage, and faulty construction of the ordinary castor; for this work I recommend the castor without a wheel. For tables and extra heavy work, the one as drawn with a wheel in the front, under the centre of action, is the best."

From this it is to be gathered that there are two varieties of the Cantilever Bowl Castor, one without roller, and the other with roller. Further, each variety, as castors generally are, is made in two forms, one as a socket castor and the other as a screw castor. Mr. Hart will make castors to suit any customer in strength and style from $\frac{3}{4}$ in. to 2 in. Those that are kept in stock, and which will meet all ordinary purposes, are made in four sizes, namely, $1\frac{1}{8}$ in., $1\frac{1}{4}$ in., $1\frac{3}{8}$ in., and $1\frac{1}{2}$ in. All are strong cast, and of brass, and are supplied in sets of four at the following prices: No. 1 Socket Castor, without Roller, from 3s. 8d. to 5s.; No. 2 Socket Castor, with Roller, from 4s. 2d. to 6s. 4d.; No. 3 Screw Castor, without Roller, from 3s. 2d. to 4s. 6d.; and No. 4 Screw Castor, with Roller, from 3s. 4d. to 4s. 10d. Plate castors, triangular, square, or round, are supplied at precisely the same prices as screw castors. In this form the castor is attached to the plate, and the plate is pierced with holes countersunk to receive the screws by which the plate is fastened to the wood.

The Editor.

# SHOP:

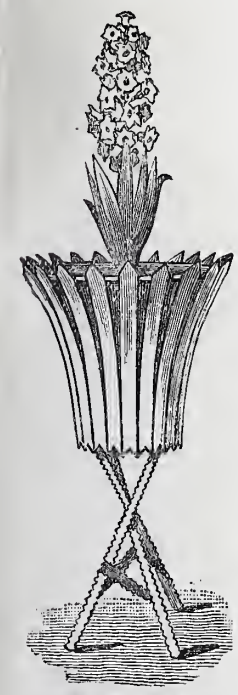
## A Corner for Those who Want to Talk It.

*** *In consequence of the great pressure upon the "Shop" columns of* Work, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* Work *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### I.—Letters from Correspondents.

**A Cheap Flower Stand.**—J. L. (*Somerset*) writes:—"The original from which the accompanying sketch is taken is made from boxes in which cheese is sent to this country, and is quite within the capacity of any amateur who has the slightest knowledge of tools and wood. The way in which I made mine was as follows: I first cut the box into strips (following, of course, the circumference) about ¾ in. wide; these again I cut into lengths of about 8 in., shaped as shown in sketch. Next I got a piece of wood 1 in. thick, and cut out a circle 4½ in. diameter. To this I nailed the strips, letting the ends come about 1 in. below the piece of wood previously mentioned; this forms the bottom of the stand. For greater strength, I put a piece of wire about halfway up the strips inside, to which I fastened the strips with copper braeing wire. The legs are of small square pieces of oak, and are so fixed by boring holes in the bottom of the stand that they will cross each other about 2½ in. from the lower part of the stand. I notched mine with my pocket-knife. There are three other short pieces put on in the direction indicated in the sketch. When all was together, I stained the whole a dark brown, finishing off with a coat of varnish, thus making the whole thing look very pretty—prettier than my drawing, as I cannot draw very well now, having allowed my talent in that particular to rust. It is cheaply made, the whole costing not more than 6d., including stain and varnish."



A Cheap Flower Stand.

**Wood-Carving Prizes.**—Wood Carver writes:—"I think the matter of judges and the adjudicating generally in wood-carving competitions is a subject which should have more attentive consideration than it at present seems to receive in many places. It is not fair to encourage a number of workers to compete for prizes unless a *competent authority* is consulted on the merits of the exhibits. I have just heard of a case at Cheltenham, where the exhibits were large and important, and a village carpenter was called in to award the prizes."—[This is certainly a direction in which our correspondent's suggestion cannot be too promptly acted upon.]

### II.—Questions Answered by Editor and Staff.

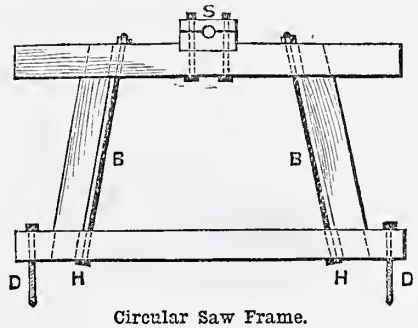
**Detective Camera.**—H. A. (*London, S.E.*).—The most simple kind workable is little more than a small box of the exact length to suit the focus of the lens used when focussed on objects about 10 ft. or 15 feet in front. Taylor, of Slate Street, Leicester, makes lenses especially suited for this work, about 6 in. focus. One of these lenses fitted into the front—which lens is flush with the front of the box, to allow the easy application of an up and down shutter—and the other end grooved to receive dark slides is practically all that is wanted with a lens of *fixed focus*. The whole may be covered in imitation of a brown-paper parcel. The slides may be changed in the ordinary way and carried in the pocket until required. A small finder may be fastened to the top of the box, easily taken on and off. Very good work has been done by a simple arrangement of this kind. H. A. will find that good work does not depend so much on the instrument as on the deftness with which it is used. Many of those in the market are needlessly elaborate. Anyone with a fair amount of constructive ability is able to make a good workable apparatus of this character. It is only when arrangements have to be made for *altering the focus* that fine and difficult work is necessary. Very good pictures have been taken by one made only of cardboard, dark slides included.—D.

**Poster Painting.**—W. H. (*St. Helen's*) and J. E. (*Skipton, Yorks.*).—Before this answer appears the Editor will have an article in his hands on Poster Painting.

**Pelican Writing Pencils.**—A. S. (*Newport, Mon.*)—Messrs. Brodie & Middleton, artists' colourmen, Long Acre, London, manufacture sable-hair pencils of the very finest description, and in all sizes. If you require an extra large size, and they have not got it in stock, they will make it to order in a few days. Of course the large size sable pencils are very expensive. The price of sable, too, has recently gone up, so you must get special quotations, and not depend on catalogues.—H. L. B.

**Gilding on Glass.**—Exile.—Burnished gilding on glass would unfortunately take up several columns of "Shop" if described fully enough to be of any use to you. Articles will, no doubt, appear in due course.—H. L. B.

**Hand Power Circular Saw.**—Compo.—Let me say that if you increase the speed of your saw, even then you will find it no easy work to drive through a piece of pine 2 in. or 3 in. deep. The fly-wheels generally fitted to such benches are too light to drive off from with belt or strap. I should advise you to go to a marine-stores, or some such place, and try to purchase a second-hand iron wheel about 5 ft. diameter, with a heavy rim; and at the same time look up a pair of stools and bearings and a piece of shafting about 3 ft. or 3 ft 6 in. long, that will fit hole in boss of the wheel. When these are obtained, then commence to make your wood frame out of 6 in. by 4 in. red or pitch pine. The frame should be 7 ft. or 8 ft. long, with four legs. At the bottom of legs there should be two pieces mortised lengthways of frame; as you wish the frame to be removable, the frame should be well mortised and bolted



Circular Saw Frame.

together. Then get four good wood screws, and if you are working on a wood floor screw the frame to the joists; if not on a wood floor, dig places for two sleepers in the ground and screw to them, fixing the frame from centre of it to centre of pulley on saw spindle; if you have room, from 12 ft. to 16 ft., as a long strap will drive with less tension and require less power to drive it. After the frame is fixed, bolt the stools on the frame; then lay the piece of shafting in the bearings, letting the end on which the driving wheel is to be keyed project the length of the boss of the wheel outside the bearing. On this end file a flat for keying the driving wheel; and on either side of the bearing farthest from wheel make a mark on the shaft, and close to the marks get two collars shrunk on to keep the shaft in place, and to prevent end play. This done, screw down top blocks, and then key on driving wheel. If there is not a hole in one of the arms of the wheel, drill one through to fix a handle to turn the wheel, and as far up as you can conveniently reach and turn the wheel. Now get a 6 in. pulley, and key on the end of saw spindle, seeing that both wheel and pulley are in line; then put on strap, crossing it if your bench is in position for crossing it. By crossing it will have greater grip on the pulley, and will not be so liable to slip. It will be seen by having 5 ft. wheel and a 6 in. pulley, that the saw will make ten revolutions to one of the driving wheel; and if you are driving a 12 in. circular saw, the traverse at point of teeth will be a little more than 31 ft. to one turn or revolution of driving wheel. Care should be taken in feeding the timber, which should be fed very slow. The annexed sketch is one side of the frame that is to carry the driving wheel, showing how it should be mortised and bolted together. B, B, are ¾ in. or ⅞ in. bolts; the heads H, H, should be let in level with the wood; D, D, are holding-down screws; S, stool and bearing.—A. R.

**Billiard-Ball Dye.**—Spot-Stroke asks for a good red dye for billiard balls. This should not be difficult, though it is a craft secret. Billiard-table makers and sellers do not dye their own balls, nor do they know how it is done. My experience with dyes is that cleanliness is one of the factors of success. The ivory must be cleansed of its acids and grease for some little distance into its surface, just as leather is, or it will not take dye or lacquer. The dye used is the result of boilings of red cloth that is left from the making up of soldiers' coats. This red is from the cochineal insect. Before putting the balls into the liquor, make a bran bath by boiling good bran for an hour; strain off the liquor, and let the balls soak in this liquor for half a day or more. Thoroughly dry the balls, avoiding the touch of the hands as much as possible; then put them in the hot red dye, and allow to remain till the proper colour. Another dye is common sumach. Boil or scald three pounds of sumach; put the prepared balls into this liquor after it has been decanted; let them be in it till it is cold. Much of the commercial dye is poor in penetrating quality, only suitable for wood or paper. If you can make your own magenta dye, here is a simple recipe. Heat commercial aniline with the tetrachloride of tin; or better, nitrate of mercury, or for cheapness, arsenic acid serves—twenty parts of the latter to twelve parts of commercial aniline, to be heated in a clean cast-iron still up to from 309° to 338° Fah. Water and aniline will pass over. After some hours, steam is blown through the mixture in the still, which brings over more aniline. The lid is removed, and the mixture allowed to cool sufficiently to be put into a large vessel, in which it is boiled with an excess of water. It is then filtered to remove insoluble matters. Common salt is added to the filtrate, which precipitates the colouring matter in a crude form. This is washed on a filter, and afterwards dissolved in boiling water. From this the magenta crystallises out in cooling, ready for use. To make the dye from the cochineal insect is a sure plan of obtaining a penetrating dye.—J. C. K.

**Looking Glass.**—S. H. (*Walsall*).—Receipes and directions for silvering glass by nitrate of silver have appeared in "Shop," and using those, it would take not quite an ounce and a quarter (1¼ oz.), or say 620 grains, to cover the quantity of glass you wish to do; but there may be something in your recipe to alter the quantities, that I cannot tell without seeing it; but, may I ask, are you going to try a new recipe upon six square feet? Would it not be better to use a small piece first? As regards the latter part of your letter, "Is it possible for an amateur to bevel the edges of glass?" I should say, Yes, it is *possible;* because, with money to buy tools, and time to gain experience, an amateur may be able to turn out as good work and do all that a professional can do.—W. E. D., Jr.

**Dulcimer Pins, etc.**—E. H. (*Bethnal Green*).—You can obtain these at almost any wholesale warehouse. My object in recommending Messrs. Chilvers & Co., of Norwich, was that, being wholesale dulcimer makers, they make a speciality of the fittings, and can be relied on to supply just what is required.—R. F.

**Bamboo.**—Victor.—Bamboos may be bent by heating them in a smokeless flame. The heat renders them pliable, so that they can be bent without much difficulty. When cold, the shape given is retained. Take care not to burn the bamboo; and to avoid this, as well as to prevent the bend being too sharp, keep it moving, and heat a length of some inches, according to the size of the work.—D. D.

**Bow Saw for Machine Saw.**—J. G. (*Nottingham*).—Half-inch is quite broad enough, if not too broad; mine is only ¼ in., and it acts well enough. The usual holes are right. I do not think that you could successfully fix a grindstone on it. I thought of doing so at one time, but abandoned the idea as not being practicable. Instead, I constructed a small compact treadle grindstone, with trough complete.—F. H. R.

**Model Wheels.**—Silicato.—As you seem to require felloes and spokes on rather a wholesale scale, you had better advertise in Work Sale and Exchange column for a band-saw man.

**Observatory Hive.**—J. J. (*Kidderminster*).—I will reply to any questions through "Shop."—Apis.

**Beehives.**—Ubique.—No instructions have been given as to the construction of the "Lanarkshire hive," nor do I know of the existence of such. There are the Stewarton, with octagonal boxes, and the Renfrewshire Stewarton, which has movable bar frames; either of which may be known locally under the term Lanarkshire. A paper on the construction of the Stewarton hive may appear later on, as it is in every respect an excellent hive.—Apis.

**Failure in Silvering Glasses.**—J. W. M. (*London*).—Your letter says that "You have followed the directions given in 'Shop' for silvering glasses, but have failed owing to holes in the foil when finished, and suggest that something else is mixed with the mercury by manufacturers, as you have seen some done, and it acted better than yours did." I think anyone of two or three things will account for your failure. Nothing is needed but mercury to pour on the foil; and part of your letter proves it when you say, "All the rest is right but these holes." But if you think differently, why did you not ask the workmen you saw what they were using? I think their reply would have convinced you. Now, in reading over your letter carefully, it strikes me that you have not used sufficient mercury, as you refer to laying it on with a hare's foot (I venture to say you did not see those workmen do that). Plenty of mercury must be used; a little will not do. It is nearly all pressed out again, and recovered when the glass is put on and weighted; but enough must be poured on at first to cover all the foil. If you only put a little in the middle and then try to spread it over the whole surface, it is sure to rot the part where it is first poured on, and holes are the result when finished, the thinnest places, of course, suffering most. For this reason, too, a stout piece of tinfoil should be chosen, as the thicker it is, the longer it will resist

the mercury; but above all, be quick in getting the glass on when once you have covered the foil. The last suggestion I make is that you get a fresh piece of foil, and at a different place, as I am told that you may sometimes happen to get hold of a piece of tinfoil which will not amalgamate with mercury because of its not being pure; I have not known it to occur, but I have it from one who has met with it, so if you still do not succeed with more mercury and stouter foil, try another shop for a better quality; but I think your mistake has been in letting the mercury remain on the foil too long before the glass is put on.—W. C. D., JR.

**Hall Lamp.**—W. H. T. (*Harringay, N.*)—We have not published working drawings of this; nor can we give you the addresses of our writers.

**Bracket.**—W. T. H. (*Wellington*).—Consult the Indexes of WORK, Vols. I. and II., for bracket designs and fret-wood dealers.

**Shooting Board.**—J. A. (*Gristhorpe*).—You should purchase the Indexes to Vols. I. and II. of WORK. Your difficulty in obtaining numbers of WORK would be obviated by subscribing for it through the publishers, Cassell & Co., Limited, London, E.C.

**Staircasing and Handrailing.**—M. A. P. (*Birmingham*) and M. T. O. (*Stockport*).—When I can meet with a man who is duly qualified in three important respects to handle this subject, it will be taken up and dealt with. Firstly, he must be thoroughly well acquainted with this branch of joinery; secondly, he must be a good draughtsman, able to put his work on paper in a clean and efficient manner; and thirdly, he must be able to write clearly and intelligibly, and capable of imparting instructions so fully and so plainly that no one may fail to understand his meaning. I have met one man, as I have said, who could satisfy the first two requirements, but he could not write. Had he remained within my reach, I would with my own hand have put his teaching, orally given to myself, into intelligible form. He did not do so, and so the thing fell through; and now I should decline altogether to undertake the task of licking crude thoughts and language into shape. Others have proposed to take up the subject; but when it has come to the scratch, they have proved unwilling—to speak in the mildest terms—to satisfy me as to their qualifications. Now you see the position, and are, I trust, satisfied with my assurance that when the right man turns up to undertake the work, the work will be done.—ED.

**Ancient Lights.**—LOTO.—This notice, which is sometimes met with on buildings, refers to lights which have become a rightful possession by the lapse of years, and which, therefore, cannot be encroached upon or impaired by any proposed new building, even though no plan or stipulation as to such lights may appear in the said light-holder's lease.

**WORK Registered.**—MEREDITH.—As WORK contains no matter which is essentially "news," it cannot be registered as a newspaper.

**Brass and Iron-Work.**—W. E. P. (*Ross, Herefordshire*).—I am unacquainted with any technical work on the subject, but you will find some useful and highly artistic designs for brass and iron in a work by A. W. N. Pugin, Esq. (1836). London: Ackerman & Co. There are examples of all kinds of ecclesiastical fittings and furniture in brass and iron-work, commencing with nail-heads, crosses, hinges, locks, bolts, knockers, chests, coffers, lamps, terminations for turrets and gables, railings, lecterns, branches for lights, windows, escutcheons, etc. As to the tools required, they may depend in a great measure upon what you want to make. The brass ornaments may be either stamped, pressed, or flied out in a press, and stamped into the required shape; or they may be spun into shape in the spinning lathe, and chased or engraved by way of ornamentation; or the brass ornaments may be *repoussé* work, entirely done by hand. By reference to Vols. I. and II. of WORK, something of all the above processes may be learned, and the suggestion of ornamental brass and iron-work has been noted; and instructions, with suitable designs, will be given in WORK as soon as arrangements can be made. Commercially, ornamental brass and iron-work is divided and sub-divided for economic reasons into many branches and processes, and can only be carried on with large capital and a thorough practical acquaintance with the business. I enumerate a few:—The designer, ornamental worker in iron, stamper, press-worker, chaser, engraver, spinner, buffer, and finisher. Then there are the maker-up or putter-together of the different parts, and the erector. A good firm for presses and American drawing machinery is Messrs. Taylor & Challen, Great Hampton Street, Birmingham; brass sheets and drawn tubes from Messrs. Tucker, York Street, Sheffield. Mr. A. Foster, Rockingham Street, Sheffield, makes and supplies tools for *repoussé* work, embossing, and chasing; and tools for engraving may be had from Messrs. John Sellers & Son, Arundel Street, Sheffield. As to your inquiry for black printed patterns, all patterns of any commercial value would be found in "The Manufacturer's Private Pattern Book," which might sometimes be picked up for a mere trifle at a dealer's in second-hand books.—N. M.

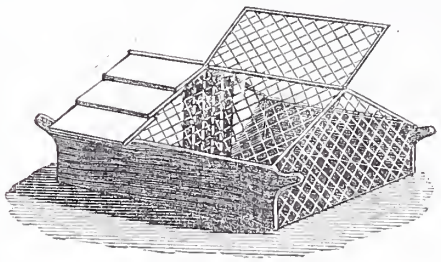
**Index.**—J. J. (*Birmingham*) and others.—The Index to Vol. II. of WORK is ready, and can be had from the publishers, Messrs. Cassell & Co., London, E.C., 1½d. post free.

**Wood Merchants.**—NO NAME.—You can get walnut at "Ware's," Kennington Lane, S.E. Consult Index to Vol. II., which is now ready, price 1d., and you will see several addresses of places you want.

**Æolian Harp.**—M. J. C. (*Glasgow*).—In Nos. 55 and 58 will be found information *re* the above. They can be had post free from the publishers, 1½d. each. The Index to Vol. II. is ready, and can be had of the publishers, post free for 1½d. It will be of great use to you for reference.

**Binding.**—BLOCKHEAD.—The four-page supplement of WORK should be pasted by "tacking" (as explained in the articles) it to the back of the section immediately preceding it. It is paged, so be careful to put it in its proper place. The fastening of the thread in sewing books is very simple. When you begin to sew, leave a long end where you started—that is, at the tail of the first section. Having passed the needle *up* the whole section, come *down* through the second; bring out the needle, and fasten the thread by tying it to the end which was left at the beginning. Now go on until you arrive at the head to the third sheet. Bring out the needle and pass it between the second and first sheets behind the thread, make a loop, and pass the needle through it and tighten up. When you come to the bottom of the fourth sheet do the same, and so on and on until the sewing is complete. I think this is simple enough without a diagram. The ends of the bands are first scraped thin; and after the end-papers have been placed upon the book, the slips, as they are called, are pasted and spread out flat upon the side of the book on the top of the end-paper. They should not be more than 1 in. long, and the reason of making them flat is to prevent them appearing like great lumps of rope when the book is opened.—G. C.

**Hen Coop.**—FACTS ON.—I give a sketch of above as supplied and manufactured by Messrs. Boulton & Paul, of Norwich. It is claimed for this coop that it is perfectly secure from inroads of vermin. The whole bottom of coop and run being



Hen Coop.

covered with 1 in. mesh wire netting, it is impossible for rats to get into it. The wire netting bottom lies flat on the ground, and can be covered with sand, or if on grass, the chicks run over it with perfect ease. When coop is shifted, all impurities fall through wire netting, and are readily swept away. Size, 5 ft. long, 2 ft. wide, 20 in. high; price, 15s.—E. D.

**Copying Printed Matter.**—W. O. J. (*Carnarvon*) will probably find photography the most satisfactory and simple way of reproducing printed matter.—S. W.

**Materials for Painting on Glass.**—G. C. (*Reading*).—Let G. C. try Messrs. Brodie & Middleton, Long Acre, W.C. They are, we believe, the London agents for the materials prepared by Mr. Hancock, of Worcester.—S. W.

**Firing Paintings on China.**—F. H. B. (*Barking*).—The home firing of painted china, as of painted glass, is generally done in what is called a "muffle"—a kind of box made either of iron or of a combination of iron and fire-brick; the "Automatic Kiln" is of this latter kind. It is said to be especially suited for amateurs. Purchasers are furnished with full instructions for fixing and using it.—S. W.

**House Painting.**—DECORATOR.—All the back numbers of WORK can be had through your bookseller or from the publishers. The Index to Vol. I., which can be had for 1d., will tell you the numbers.

**Scene-Painting Materials.**—W. P. (*Burton-in-Lonsdale*).—Any dealer in colours could supply you with paints. Consult the advertisements in WORK.

**Self-Centring Chuck.**—AMATEUR.—It is out of the power of an ordinary amateur to make a self-centring chuck. To be true to their name, the chucks must be exact in every part, and the most perfect of workshop appliances is needed to effect this. Even when a perfect chuck is made, having each of its jaws at an equal angle to each of its neighbours, and moving each jaw equally in obedience to the moving screws or spiral groove, a little variation of hardness in the jaws and some violence by the turner, and the accuracy is gone.—B. A. B.

**Soiled Book.**—J. B. (*London, W.C.*).—If the title-page of your book has only been soiled by "damp fingers," it could be cleaned by rubbing it carefully with bread-crumbs or indiarubber. If the latter is used, be careful not to rub too hard, or the cure may be worse than the disease. If there is any oil upon it, it should be washed with spirits of turpentine very carefully. The turpentine will run into the paper and turn it quite black-looking, and you will think it is completely spoiled; but it will all dry out, and the oil-stains will have disappeared.—G. C.

**Baking Bicycle Enamel.**—C. E. B. (*Poplar*).—The stove is heated up to 350° or 400°, using a thermometer. It is supplied with an arrangement of gas-pipes underneath; and a good supply of gas from the main is required. The work being first thoroughly cleaned from rust and grease, is coated with stoving enamel, called first coating, put in the stove for several hours. The first coat, when hard and cold, is smoothed with Tripoli powder, and another coat of finishing stoving enamel applied and baked as before. The stove has several angle iron ledges inside, on which various bars rest, on which to place or hang the work. The apparatus, including gas connection, would cost from £11 to £12; and unless your correspondent means to go into the thing on a large scale, he had better send out his bicycle or bicycles to a "baker."—A. S. P.

**Small Organ.**—GOOD TIPS.—It is possible to build a useful little pipe organ which will only occupy the same ground space as a moderate-sized American organ; but one must not expect too much from so small an instrument. The following specification is for an instrument which would be 4 ft. to 4 ft. 6 in. wide, and about 20 in. or 21 in. deep, exclusive of projection of keyboard, and 8 ft. to 9 ft. high—

| | | | | |
|---|---|---|---|---|
| 1. | Dulciana ... ... ... | 44 | pipes | 8 feet tone |
| 2. | Stopped Diapason (bass) ... | 12 | ,, | 8 ,, |
| 3. | Small Gamba, Keraulophon, or Vox Angelica ... | 44 | ,, | 8 ,, |
| 4. | Swabe flute, for principal.. | 56 | ,, | 4 ,, |
| | Total ... | 156 | | |

The sound-board for this would be about 4 ft. long and 18 in. wide if made singly; but it would be better to make it in two, and 3 in. or 4 in. in length might be saved, and more room gained for channels. Thus, make the front portion 3 ft. 9 in. long and 10 in. wide, with forty-four channels to accommodate the forty-four pipes in the treble of Nos. 1, 3, and 4. The back portion would be 3 ft. 9 in. long and about 6 in. wide, and would accommodate the twelve large pipes of Nos. 2 and 4, each standing in a single row. These two sound-boards would be united over a single wind-chest. The height of the instrument could be reduced, if required, by planting off a few of the largest pipes of each stop either at the front or ends. An octave coupler could be added if required, but would, of course, necessitate an extra octave of small pipes for each treble stop. The whole affair could also be enclosed so as to obtain a general swell. As regards a book on the subject, see replies in back numbers—*e.g.*, the last one mentioned in the answer by "K" (column 1, page 649, of No. 92) would just suit you, as it contains full and clear instructions for making every part of the instrument.—M. W.

**Writing Cabinet in Carved Work.**—X. L. U. MAY (*Hebdon Bridge, Yorkshire*).—I am obliged to you for your interesting communication respecting the construction of a writing cabinet from an old carved oak chest that belonged to your great-grandfather. It is most creditable to you that you should have evolved so good a piece of work from the materials at your command. I cannot, I regret to say, find room for its appearance in WORK; and your drawings shall be returned to you if you will favour me with your actual name, or certify me that the initials and name given above, which are open to suspicion, are those which really and truly belong to you.

**Artistic Lithography.**—H. G. (*Coventry*).—The above series is commenced in No. 106 of WORK.

**Screws.**—MECHANIC (*Leeds*).—An article on the above appeared in No. 109.

**Ladies' Writing Table and Escritoire.**—H. W. (*Rochester*) asks for a design for the above. The very thing he asks for he will find given in No. 56 of WORK.

**How to Net a Garden Hammock.**—F. W. P. (*London, W.*).—The article on the above appeared in WORK, No. 79. The Index to Vol. II. is now ready, and can be had from the publishers, post free 1½d.

**Clock Cleaning and Repairing.**—E. D. (*Deptford*).—The clock cleaning and repairing articles appeared in Vol. II. of WORK. You can get the Index to the volume and see what numbers you want. All the back numbers are in print, and can be ordered through your bookseller or from the publishers.

**Castings.**—B. (*Dundee*).—Having answered your questions as to castings, we can do no more.

**Bellows.**—E. A. and F. G. (*Bristol*).—Frame your reply so that it will be useful to all readers, and not to CARO only. All replies must go through "Shop."

**Brass Angle and Pieces.**—BERTIE.—Apply to any tool maker who supplies cabinet ironmongery. Many names have already been given in the pages of WORK.

**Dry Earth Closets.**—UBIQUE.—For the construction of an earth closet, sifted ashes mixed with fine dry mould would do excellently.—APIS.

**Colouring Clays.**—WORKITE.—Clay has many names. The chief one is "silicate of alumina" in one of its aspects of composition—the most general

one. Clay is the result of the decomposition by chemical and mechanical action of water and air on rock containing felspar, quartz, and mica; and by the action of water and air at certain temperatures it can be resolved into rock again. If for pottery, or extraction of metals or pigments, salts or acids, the processes are amply detailed in Roscoe's "Inorganic Chemistry" (Macmillan, 1880); and John Hunter's "Short Manual of Analytical Chemistry" (Simpkin and Marshall, 1887). W. A. Miller's "Text-Book of Chemistry" is a good book (Longman & Co., 1871); and a more extensive work, "Elements of Inorganic Chemistry," by the same author and publishers (1873); also Bloxam's "Chemistry" (Churchill & Co., 1890). In recommending these almost exhaustive treatises on earth clays, first, you will have a new vocabulary and a symbolisation of names demonstrated algebraically to learn; but that need not concern you much—it does not ninety-nine hundredths of the workers in clay, chalk, etc., for whom these are almost sealed books—and the formidable formulas you need not investigate for accuracy; every new decade modifies the past decade's assumptions and conclusions. One or two works have the word loam in the indices, and in the body of the work simply define it as "clay" or "impure clay," "clay from which bricks are made." It is an earth far too valuable for brickmaking, as well as often unfit. Some of it is worth 3s. 6d. per square yard, to be dug up by the buyer and carted several miles. It is the garden earth of these islands. The value of these books is in their chemical analysis of the earth's crust. They are beginning to learn about the fertilisation of earths. In following their guidance, you will find the track clear for you, and learn that, in operating chemically upon clays, you obtain aluminium and other metals; and learn also that there is about two pounds of aluminium and iron in every red brick that is used in buildings. The study of pigments in earths you will find interesting. What in wet weather we call mud is often paint, as umber, ochre, sienna, and various other clays that yield colour for the painter. Broadly defined, clay contains iron: ferro-oxide. Marl contains lime carbonates. Loam the chemists have not done justice to as the most fertile of earths. England now imports one-third of its food; without loam it would have to import two-thirds, and half its flowers also. The fossils, so valuable as manure, are well understood by farmers, even without chemical knowledge. Coprolites, which when ground to powder smelling and looking exactly like curry-powder, used to sell at £20 a ton. It is the remains of saurian animals, the teeth often found still perfect in shape. Pipe-clay, china-clay, chalk, etc., will yield new elements under the action of the blowpipe, pipe-clay becoming a colourless glass. The microscope will be essential for your studies. The clay—silicate of alumina—is mainly from granite. Its quartz is translucent, its felspar is cream-coloured, and its mica of glittering scales. In mixing clays you obtain porcelain. Thus: Kaolin or china-clay, 62 parts; Bougival chalk, 4 parts; Humont sand, 17 parts; felspar, 17 parts. This is the formula for the celebrated Sèvres porcelain. For pottery, clays need preparation and weathering, and have to be mixed with sand, chalk, ashes, etc., which prevent shrinking and warping under the action of heat. The clay worker puts back into the clay its rock-forming constituents, which the sun and rain had taken out. Glazes on pottery may be as simple as a dust over of sand, and kilning with salt in the furnace of kiln; or, for fine work, silicate of soda and lime, also silicate of potassium and lead. For colours from clays and earths you will have a vivid world of beauty open to you, and have to learn the new vocabulary of their names, which will mar your progress considerably if you wait to do that. You will be imperceptibly carried onwards in your studies to wider vistas of the unknown. The lapis lazuli is a silicate of alumina combined with lime, soda, sulphuric acid, and sulphur—the source of the once costly regal colour, ultramarine, now one of the medium-priced pigments made from clay: that is, kaolin, 100 parts; sodium carbonate, 100 parts; sulphur, 160 parts; and aluminium silicate, 17 parts, or also an addition of charcoal, 12 parts. In operating chemically upon clay you will soon find you have the metal aluminium. You will find you produce alum and iron, especially in the red clays. This alum, you will find, embodies as elements certain metals—but I must not detail the process of aluminium making, as it is now so well known. Perhaps you are near potteries, and can get to work in one to learn all about clay technically. China clay is called by chemists "hydrated aluminium silicate." Besides making hard china-ware, it is used as a dressing for paper, calico, and fustian. In this last form it is a source of permanent injury to health of wearers, by attracting damp to clothes worn by hard workers having fustian materials for make or linings; causing rheumatism to the wearers by the damp held by this clay. Its use thus ought to be penalised. Chalk—the remains, mostly, of marine shells—differs in density and fineness. The finest natural chalk is used for billiard chalks without preparation of any kind. England's manurial earths are but imperfectly studied by scientists, though known to farmers and old writers like Jethro Jull, who used common terms in speaking of them in his excellent writing on farming. Clay is the most valuable of manures for peat land, also with peat combined for light sandy land. Peat is excellent manure for stony land known as "stone brash." Chalk has general excellence to manure all soils. This interchange of soils serves another purpose; it eradicates and kills perennial weeds. Poppies cannot live in clay soils; chalk kills the heather; and many services to agriculture result from mingling of soils.—J. C. K.

**Druggists.**—F. L. W. (*Sandown*).—I do not know of any special firms who can be called "wholesale druggist to the cabinet and polishing trades;" but if you mean those who can supply lac, resin, methylated spirit, and such like used in making polish and varnish, you will find Burgoyne, Burbidge & Co., 16, Coleman Street, E.C., able to do the needful. Bottles can be got from Breffitts, 83, Upper Thames Street: or from Wright, Urmson & Wright, Southwark Street, London.—D. A.

**Jewel Cabinets.**—Z. L. R. (*Newhaven*).—I can hardly comprehend whether you want a swinging glass on top for toilet purposes or if I am to form my conclusions from the continuation of your letter, which says, "For a watch to hang on." At any rate, it matters little whether it be a swinging glass or a swinging lump of wood; in the former case, you must rebate it to admit the glass, and in the latter instance, hollow it slightly on the front for the watch's reception. A small peg inserted in the top of the stand will support the watch. The stand may be secured by thumb-screws between two brackets, the latter being further united by a cross-rail (as in Fig. 3), and the whole secured to the back of the cabinet. You ask for drawers and folding doors. As my suggestions may be of use to some who would not wish to repose the article in the company of a dressing-table, I have supposed

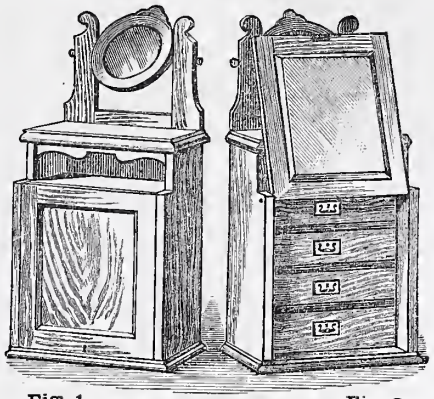


Fig. 1. Fig. 2.

Fig. 3.

**Jewel Cabinet. Fig. 1.—Jewel Cabinet. Fig. 2.—Cabinet with Flap Door opened (may be fitted with Mirror). Fig. 3.—Section of Back Uprights and Rail.**

that the door should open upwards, and be fitted on the inner side with a mirror. For appropriate remarks concerning this part, read through my article, "A Combination Bedroom Suite" (No. 26, Vol. I.). For the purpose of retaining the glass door in an elevated position, it is advisable to construct the cabinet in such a way that the front edge of the top board lays a short distance back from the front of the main portion of the article. The door will then lean against the top board. The former must be pivoted at the top between the sides of the cabinet. You might groove and tongue the sides and the top (dovetail form); but screwing will be sufficient for the back and bottom boards. Drawer runners, also, might be tongued to the sides. Have sunk handles to the drawers, that they may lay flush.—J. S.

**Chasing.**—MECHANIC.—In the first place, you must know that a knowledge of this trade is usually gained by apprenticeship, and that, although the process is fully described in the article in No. 92, Vol. II. of WORK, it is not to be expected that a person can at once jump into it and earn a living without much practice. The occupation is a very clean and pleasant one; and the remuneration depends on ability. An average workman can earn 50s. per week comfortably, and at present work is plentiful; but it is an occupation that depends largely upon fashion. Chased work is greatly in demand at present; and although a first-class workman can always depend upon employment, when the fashion changes some will have to go. However, if you are determined to go in for it, my advice is as follows: Keep to your present employment, if you have one: purchase the necessary tools for chasing, and work at home in your spare time until you are perfect. Then, when you think that you are competent, take a sample of your work round to the manufacturing silversmiths—you will get the names from the directory—and ask for a job; you will then see how you stand. London, Birmingham, and Sheffield are the three towns where this work is carried on. Most of the work is done in shops, not at home. I am not well acquainted with the London tool-makers, but write to Towneley, Bull Street, Birmingham, for their list. The snarling-iron is not usually quoted in the list, and would have to be ordered; it might cost about 10s.—F. R. H.

**Xylonite.**—J. W. P. (*London, E.C.*).—An article dealing with the use of xylonite for fretwork is in the Editor's hands, and you will find a great deal of information which will be useful to you and your chums who are fret-cutters. In the meantime, I may tell you that the best way to fasten sheets together for sawing several at a time depends on the thickness of the material. If this is less than about ⅛ in., I find it best to glue them together, with a piece of paper between; thicker stuff may be fastened with wire pins in the waste, but even for this glue is better. Certainly an ordinary drill will do. You could easily have ascertained this for yourself by experiment. I quite agree with you that there is a good deal of monotony in always using wood for fretwork, and that novelties should be welcome to the majority. Have you ever tried marquetry cutting? There is plenty of variety and interest in this work and its attendant operations. Please note that xylonite is spelt with an X, not with a Z, as you spell it.—D. D.

**Chessmen.**—W. E. H. (*Hebburn-on-Tyne*).—There is no reason why chessmen should not be made of imitation ivory. If you had taken the trouble to read WORK recently, you would have seen from the article on "Xylonite: its Nature and Use," on page 787, No. 101, Vol. II., that ample information is given about it. If you want your chessmen to resemble real ivory in appearance, get the "grained ivory" xylonite. You cannot make it. Buy the raw material, and do the carving, etc., yourself.—D. D.

**Tennis Shoes.**—H. B. W. (*Rugby*).—I cannot say whether the method of soling mentioned on p. 808 would do for tennis shoes, but I suppose so. The gutta-percha will not require stitching to them any more than to boots. If you follow the directions given, it ought to be sufficient. I am not acquainted with the tradespeople in Rugby, but if there is a dealer in indiarubber or waterproof goods, even if he does not keep gutta-percha in stock, he can get it for you in the ordinary course of his trade.—C. E. M.

**Table.**—W. E. (*Wimbledon*).—Undoubtedly the best way of finishing your table top will be by polishing it. If carefully done, no injury should arise to the painted decoration, which, I presume, is done with ordinary oil colours as prepared for artists' use. The enamelled part will probably not require anything doing to it. Probably you will get an equally satisfactory result by simply varnishing the decoration with a brush, using artists' copal varnish. I do not think it would be of any advantage for you to varnish first and then polish; but if varnish alone does not suit, there can be no harm in your trying.—D. A.

**Xylophone, Wood, etc.**—E. F. P. (*Leicester*).—The best wood for the notes is rosewood, but you may use oak or pine with very good results. Pieces with knots should be avoided; and a more even tone is said to be got if all the pieces are cut from one plank. The notes are 1½ in. wide and ⅝ in. thick, and rounded on the upper side. Holes are bored about 1½ in. from the ends, and a cord is put through, with a knot between each note. If you want semitones you must have three cords, and put the semitones in groups of two and three in one row, and the naturals in the other row, the middle cord passing through both naturals and semitones, and arranging them similar to the keys of a piano. To find the approximate length of the notes, mark thirteen lines at equal distances, and at right angles to a base line. Make the longest line 12 in. (which is E), and the shortest 8 in. (which is its octave), and draw a line between the points thus marked. The intermediate lines will give the length of all the notes between; and by drawing more perpendicular lines at either end, the same distance apart, and prolonging the line, you can get the length of the notes above and below. They are laid on three straw ropes about ¾ in. diameter, and played by two beaters of hard wood. You can tune the notes accurately to a piano by cutting a little off the ends to sharpen them. The Editor has an article and drawings on the subject, which will be printed as soon as space can be found for it, which will be of service to you. You can make one with brass tubes in the same manner, drilling holes through the tubes for the cords, and using tubes from 1 in. to ¾ in. diameter. You can get the lengths in the same manner, and tune them by filing a little off the ends till of the right tone.—M.

**Petroleum Engines.**—J. H. D. (*Halifax*).—The petroleum engine is very similar in character to the gas engine. In one form the oil is not vaporised, but is drawn into the cylinder in fine spray mixed with air. The action, or cycle, as it is termed, is as follows: an outward stroke of the piston draws in behind it a mixture of air and petroleum spray; the next inward stroke compresses the mixture to about three atmospheres; and at the commencement of the next outward stroke the mixture is fired by a gas jet in a suitable slide. This engine is single-acting, and makes one effective stroke in four. During the fourth stroke, which completes the cycle, the products of combustion are driven out at the exhaust. In another form of petroleum engine, the oil is forced by air pressure into a vaporiser appended to the cylinder, and there mixed with air under pressure as it is vaporised. The heat for vaporising is at the start furnished by a jet under the vaporising chamber, and afterwards maintained by the heat of the exhaust. One stroke in four is effective, and the mixture is fired by an electric spark from a coil excited by one large bichromate cell. The impulses occurring at such comparatively long intervals, these motors require

much heavier fly-wheels in proportion to their power than steam engines, to ensure steady running. The cylinder is surrounded by a water jacket, to prevent over-heating. It has been proposed to make the cylinder with external ribs to carry excessive heat off by air currents, and so dispense with the water tank; but I do not know if this has proved a success. It is said that these engines do not require cylinder lubrication.—F. C.

**Shoe Blacking.**—SHOEBLACK.—There are a great many recipes for making both liquid and paste blacking, all more or less good for the purpose. The great secret in successfully making all the various blackings is the proportions of the ingredients used, the quality of them, and the perfect and careful mixing, so as to get a smooth, even product. Unless this is done, no satisfactory result can be obtained. Blacking from the following recipes may be made in large or small quantities without the use of machinery; but where large quantities are to be produced, it would be madness to attempt it without its aid. The recipes given are known to be good; but unless it is intended to make it a business to manufacture and sell, it would be a great waste of time and trouble to attempt it, as it can be bought so cheaply and so good. Liquid blacking:—Take of bone-black—not lamp-black—16 parts; treacle, 12 parts: oil of vitriol, 3 parts; seal, cod, or sperm oil, 2 parts; gum arabic, 1 part; strong vinegar or sour beer, 48 to 50 parts—all by weight. The first step is to place the bone-black in a large wooden, stoneware, or enamelled iron vessel, to which add the oil, and rub and stir them well together; when this has become a smooth, even mass, gradually add the treacle, still rubbing or grinding the whole together all the time each ingredient is being, and also after each is, added, until the oil is thoroughly amalgamated or "killed," and continue to grind or rub the mixture for some considerable time. Now dilute the oil of vitriol with about three times its bulk of water, doing this very carefully to avoid the chance of accident, and then add it, a little at a time, to the other ingredients, stirring them briskly during the time of addition and for some time afterwards, until it has become quite smooth and homogeneous. It should then be allowed to stand for two or three days longer, stirring in the meantime for half an hour daily. Having meantime dissolved the gum in the vinegar, add the solution gradually to the rest, and stir it briskly for some time, and again daily for three or four days. It will be found beneficial if all the ingredients, except the vitriol, be made hot before mixing, as the shining quality of the product will be greatly improved, and the time required in the manufacture will be shortened thereby. Another recipe is: 16 parts of ivory-black, 8 parts of treacle, 4 parts oil of vitriol diluted with 2 parts of water, 2 parts of the same kind of oil as in the former recipe, 1 part of gum arabic diluted in 64 parts of water for the final dilution in place of vinegar; all to be mixed and treated as in the first case. This makes an excellent blacking. Another recipe is the same as the last, but only taking 6 parts treacle, 1 part of oil, and omitting the gum arabic. This also makes a good blacking. *Paste Blacking.*—Take of india-rubber oil, ivory- or bone-black, treacle, and gum arabic, the same proportions as are given for the liquid blacking, but take care to dissolve the gum arabic in vinegar, using only one quarter of the proportions given in the other cases. The mass, when mixed, must be stirred daily for a week, when it will be ready for putting up. Another recipe for paste blacking is as follows: Ivory-black, 1 part; treacle, ½ part; sweet oil, ½ part. Mix them well together, as in the other cases, then stir in a mixture of hydrochloric acid, ½ part; oil of vitriol, ¼ part (each separately diluted with twice its weight of water before mixing them). The difference between liquid and paste blacking chiefly consists in the greater or less amount of liquid employed, and not so much in the materials and proportions. Blacking, both liquid and paste, should be kept in a cool and moderately dry place, and kept carefully corked, as exposure to the atmosphere is found to destroy most of its best qualities. I am not aware of any book being published on the subject, nor does it seem one of sufficient interest to induce a person to encounter the expenditure of time and labour needed to produce it.—C. E.

**Drawings of Steam Engines.**—H. M. (*Liverpool*).—Such drawings as you inquire about are not kept on sale. You should apply to some mechanical engineer, who may have sets of working drawings, tracings of which he might supply to you. As a rule, manufacturers do not supply tracings unless an order is in view, and then working details would not be given. The cost will depend upon the size and amount of work in the drawings.—F. C.

## III.—QUESTIONS SUBMITTED TO CORRESPONDENTS.

**Glass Writing.**—W. T. G. (*Bristol*) writes:—"I have noticed on glass signs letters that look like mother of-pearl. I shall be glad if anyone can inform me where it can be obtained, the cost, and whether it is made in leaves like gold-leaf."

**Stereotyping.**—S. T. (*York*) writes:—"Can any of the readers of 'Shop' inform me if the dipping-pan is now used for stereo work? What is the use of the floating plate? How should the plaster mould be placed in the pan—face up or down? on the floating plate or on the bottom of the pan?"

**Clay Mixtures.**—HEATHFIELDS writes:—"Will any reader give me information about building with clay mixed with straw? It was, I believe, common many years ago in some parts of the country for cottages, and was very warm and comfortable. The walls were very thick."

**Fret Machine.**—D. B. (*Wymondham*) writes:—"Seeing in your valuable paper WORK, page 846, No. 104, a description of a fret machine, will J. H. W. (*Chatham*) kindly inform me as to measurements, and how to make it?"

**Sharpening and Clipping Machines.**—W. B. B. (*Edinburgh*) writes:—"Can any reader give me any information as to how horse-clipping machines are re-sharpened?"

**Fish Stuffing.**—F. M. (*London, N.W.*) writes:—"Will any reader give me information on stuffing fishes?"

**Staining.**—J. W. B. (*Huddersfield*) asks:—"How can I stain oak, birch, etc., black by a kind of liquid which will sink into the wood; for when oak is shut up tight in a box with strong ammonia, the strong scent or stench causes it to become brown. What will stain other woods brown to match it, and sink in also?"

## IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**Turned Wood Cases.**—CHEMICUS writes, in reply to W. H. (*Stirling*) (see page 14, Vol. III.):—"I have found those manufactured by Messrs. E. B. Estes & Sons, of New York, to be both *good* and *cheap*. The *sole* English agents are Messrs. Kilner Bros., King's Cross Station, London, N. W. H. cannot do better than write to the latter for illustrated price list, which also contains several other kinds of turned wood goods."

**Carved Wood Bellows.**—TOPO writes, in reply to CARO (see page 14, Vol. III.): "Why does not CARO finish off his carved bellows himself, and enhance the pleasure of his work by making it complete throughout? It is simple enough; and of course he could save money by doing it himself. Examine an old pair of bellows (or buy a cheap set for the occasion), get a nozzle and tacks or brass-headed nails from the ironmonger's, and leather from the leather-seller's, and it is soon done. Or he can read instructions and see where materials are to be had in an excellent little work, 'Hints on Wood-Carving,' by Miss Rowe, School of Art Wood-Carving, City and Guilds Institute, South Kensington (price 1s.), page 71. I do not know where he could get prepared wood from; but no doubt Miss Rowe would be pleased to inform him, if he would drop a line to her as above, enclosing stamp for reply. Mr. E. Rogers, of Maddox Street, London, W., also furnishes all materials for wood-carving."

**Iron Lasts.**—W. G. (*London, N.W.*) writes, in answer to W. S. (*Highbury*) (see page 830, Vol. II.):—"You can get them at Penton and Sons', 1 and 3, Mortimer Street, W. (opposite Middlesex Hospital). They sell them in pairs—gentlemen's, 3s. 9d.; ladies', 2s. 9d.; youths', 2s. 9d.; boys', 1s. 9d.; children's, 1s. 3d."

**Dry Battery.**—H. E. (*London, N.W.*) writes, in reply to ELECTRIC (see page 14, Vol. III.):—"To make a dry battery, line some battery cells with stout sheet zinc, leaving a lug for connection (salt jars answer admirably, or for a smaller size those straight glass pound jars without any neck that jam is sold in). Place a carbon plate in centre, and fill in with the following mixture: Dissolve in a pint of water 1 oz. each of chloride of zinc and chloride of ammonium (sal-ammoniac), then add 1 oz. of oxide of zinc, and then sufficient plaster of Paris to make a rather sloppy paste. As the plaster would soon set and harden, add a small quantity of glue or gelatine dissolved in a portion of the liquid. When firm, pour melted paraffin wax over the top, to prevent evaporation. Make two air-holes through the wax, and keep in a cool place. Agglomerate Leclanché cells can be transformed into dry batteries by mixing with the ordinary solution—plaster and gelatine—and sealing over with wax. I had some of the latter working very satisfactorily; but being mixed without the gelatine, and kept in a rather warm place, they dried up in about five months."

**Engraving.**—L. S. L. (*Kirkcaldy*) writes, in reply to C. P. (*Wanstead*) (see page 765, Vol. II.):—"A very simple way to engrave the names mentioned by C. P. (*Wanstead*), or such-like work, is to heat the plate in front of a fire or over a spirit lamp; rub the whole surface, both face and back, over with a piece of paraffin wax, and when quite cool, write with a strong needle point, after which the plate should be immersed in a bath of nitric acid and water until the writing is bitten sufficiently deep. Should the plate be attached to a leather collar, of course it must first be removed, or a 'wall' formed round the space to be occupied by the writing. This also can easily be done with the paraffin wax. With ordinary care very beautiful results may be obtained."

## V.—BRIEF ACKNOWLEDGMENTS.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—M. D. C. (*Liverpool*); T. E. (*Liverpool*); T. A. G. (*Stratford, E.*); DOWN; JOINER; A. H.; INQUIRER (*Birmingham*); F. R. H. (*Regent's Park, N.W.*); J. S. (*London, W.C.*); J. W. (*Edinburgh*); C. H. B.; A CONSTANT READER (*Dewsbury*); T. M. (*Gateshead-on-Tyne*); F. C. (*Manchester*); R. E. A. (*Sheerness*); DESIGNER; J. G. P. (*Crewe*); J. C. (*Bristol*); H. W. (*Wimborne*); J. H. I. (*St. Helen's*); F. C. (*Peckham*); W. M. (*Market Drayton*); INQUIRER (*Eccles*); B. A. B. (*Hampstead, N.W.*); H. D. P. (*London, E.C.*); G. P. (*Camberwell, S.E.*); F. P. (*Taunton*); J. W. (*Liverpool*); T. S. (*Carlisle*); J. G. (*Glasgow*); G. S. L. (*Hampstead, N.W.*); J. J. (*Stoke-on-Trent*); W. J. D. (*Manchester*); PEN AND INK; CHECKEREO; H. W. (*London, S.W.*); G. H. (*Darlington*); C. E. (*London, N.*).

CHEAP EDITION. Price **9s.**

**Electricity in the Service of Man.** A Popular and Practical Treatise on the Applications of Electricity in Modern Life. With nearly 850 Illustrations.

"All the useful applications of Electricity are described in its pages. In that respect it has no rival."—*English Mechanic.*

CASSELL & COMPANY, LIMITED, *Ludgate Hill, London.*

Price **2s. 6d.**

**Numerical Examples in Practical Mechanics and Machine Design.** By ROBERT GORDON BLAINE, M.E. With an Introduction by Professor JOHN PERRY, M.E., D.Sc., F.R.S. Twenty-Six Diagrams.

CASSELL & COMPANY, LIMITED, *Ludgate Hill, London.*

Price **2s.**

**Elementary Lessons on Applied Mechanics.** By Sir ROBERT STAWELL BALL, LL.D., Author of "The Story of the Heavens." With 140 Questions for Examination.

CASSELL & COMPANY, LIMITED, *Ludgate Hill, London.*

NEW AND ENLARGED EDITION. Cloth, **3s. 6d.**

**Colour.** A Scientific and Technical Manual treating of the Optical Principles, Artistic Laws, and Technical Details governing the use of Colours in Various Arts. By A. H. CHURCH, Professor of Chemistry in the Royal Academy of Arts, London. With Six Coloured Plates.

CASSELL & COMPANY, LIMITED, *Ludgate Hill, London.*

NEW AND ENLARGED EDITION. Price **1s.**; or in cloth, **1s. 6d.**

**Photography for Amateurs.** A Non-Technical Manual for the Use of All. By T. C. HEPWORTH. With Illustrations.

CASSELL & COMPANY, LIMITED, *Ludgate Hill, London*

WORK

*is published at La Belle Sauvage, Ludgate Hill, London, at 9 o'clock every Wednesday morning, and should be obtainable everywhere throughout the United Kingdom on Friday at the latest.*

**Best Books** on Lathe, 3s.; on Screws and Screw-making, 3s. Catalogue of best English and American books on mechanical subjects, 6d.—Published and sold by BRITANNIA CO., Colchester, Makers of 300 varieties of engineers' and amateurs' tools. [10 R

**Carvers' Tools and Carpenters' Tools** at Clarke's Tool Stores, Exeter. New Illustrated Catalogue one stamp. [12 R

**Cycle Parts.**—Any part required at lowest possible prices. Safeties from £6.—BOLTON, Burmantofts, Leeds. [13 R

**Twelve Full-Size Fretwork Designs,** 7d. and 1s. 1d., free. Forty smaller Designs, 7d., free. Catalogue of miniatures, 6d.—TAYLOR'S Fretworkeries, Blackpool. [15 R

**Stencilling.**—An Improved Method.—By using the Stencil Roller instead of the brush superior artistic work is produced. No tearing of ties, no blurred edge; the work comes out clean and sharp like print.—Manufactured by I. IRVING (1s. 6d., 2s., 2s. 6d.), 33, Mill Road, Northfleet, Kent. [16 R

**Brass Castings,** Antique Cabinet Furniture, Lacquering, and Bronzing.—T. JOYNER, Poole, Dorset. [2 S

**Wanted, Mitre Machine,** Bookbinder's Sewing Frame, and an Edge Plough; second-hand, good condition.—EVES, Aberdovey. [1 S

**Safety Bicycle,** diamond frame, cushion tyres, ball bearings throughout (including pedals), good make, splendid mount, faultless condition, lamp and gong, easy running machine, and good hill climber; £7 17s. 6d., rare bargain; approval with pleasure.—W., 34, Hill Street, Ipswich. [3 S

**For Sale, Boiler** (best block tin), containing safety valve, steam tap, whistle, three small taps; what offers?—Apply, GILLARD, Swain Street, Watchet. [4 S

# A WONDERFUL MEDICINE.

# BEECHAM'S PILLS

Are universally admitted to be worth a Guinea a Box for Bilious and Nervous Disorders, such as Wind and Pain in the Stomach, Sick Headache, Giddiness, Fulness and Swelling after Meals, Dizziness and Drowsiness, Cold Chills, Flushings of Heat, Loss of Appetite, Shortness of Breath, Costiveness, Scurvy and Blotches on the Skin, Disturbed Sleep, and all Nervous and Trembling Sensations, &c. &c. The first dose will give relief in twenty minutes. This is no fiction, for they have done it in countless cases. Every sufferer is earnestly invited to try one Box of these Pills, and they will be acknowledged to be

**Worth a Guinea a Box.**

FOR FEMALES THESE PILLS ARE

"A priceless boon, a treasure more than wealth; the banisher of pain, the key to health."

These are FACTS testified continually by members of all classes of society, and one of the best guarantees to the nervous and debilitated is,

***BEECHAM'S PILLS have the Largest Sale of any Patent Medicine in the World.***

Prepared only by the Proprietor, T. BEECHAM, St. Helen's, Lancashire, in Boxes 9½d., 1s. 1½d., and 2s. 9d. each. Sold by all Druggists and Patent Medicine Dealers everywhere. *N.B.—Full Directions are given with each Box.*

---

**FLUID WATER RESISTING GLUE** (*Patent*) PATENT TINS.

*Invaluable for all Out and Indoor Repairs.*

**FLUID WATER RESISTING GLUE** (*Patent*) PATENT TINS.

No Brush—No Boiling—Will securely join Wood, Glass, China, Metals, &c.

*By Post, 8d. and 1s. 9d. per tin. Through Ironmongers, Chemists, Chandlers, &c., 6d. and 1s. per tin.*

Manufactured only by THE WATERPROOF GLUE CO., 62, Dale St., LIVERPOOL.

Wall Bracket. Price 5d.

### THE MOST PROFITABLE AND FASCINATING OF ALL HOME PASTIMES. EASILY LEARNT.

J. H. SKINNER & Co. having *Dissolved Partnership*, are offering their *Enormous Stock*, including 250,000 FRETWORK PATTERNS and 100,000 ft. of Solid and Three-Ply FRETWOOD, Veneers, &c.; 1,000 Gross of FRETSAWS, besides an immense quantity of TOOLS, OUTFITS, &c., as a special inducement to their customers to order at once.

**4,500 1s. Books of Fretwork Patterns**, each containing Twelve Large Sheets, beautifully lithographed, none of which would be sold retail at less than 2d., and many at 3d. and 4d. each; also

**1,200 2s. 6d. Books of Fretwork Patterns**, containing Twenty Sheets, 19 in. × 12 in., of new designs, many of which would retail at 6d. each. These Books,

**£375 in Value, will be GIVEN AWAY.**

Amateur customers ordering 5s. worth of designs from Catalogue will be presented with one of the above 1s. Books. Those ordering 10s. worth will receive a 2s. 6d. Book.

**An Allowance of 10 per Cent.** *in goods* will be made on all mixed orders for Wood, small Tools, Saw Blades, and Designs, amounting to 10s., and **15 per Cent.** on orders amounting to 20s. and upwards. NOTE.—*This reduction does not apply to Treadle Machines.*

N.B.—A SPLENDID OPPORTUNITY FOR BEGINNERS.

**Complete Fretwork Outfit**, comprising 12-inch Steel Frame, Forty-eight Saws, Awl, File, Four Designs (with sufficient Planed Wood and 1s. Handbook on Fretwork). **An Archimedian Drill,** with brass handle and Three Bits, will be **SENT GRATIS** with each Set. Post free for 3s. 6d. Outfits on Card, 1s. 6d. and 2s. 9d., post free. 6 ft. 2nd quality assorted planed Fretwood, 1s. 9d.; post free, 2s. 6d. 12 ft. ditto, ditto, 3s.; post free, 4s. 3d.

**SKATES!!!**—EVERY PAIR WARRANTED.—Sizes, 7½in. to 12 in. No. 1, Unpolished Beech, 10d. per pair. No. 2, Polished Beech, 1s. 6d. per pair. No. 5, "Acme" pattern, all steel, 3s. per pair. No. 7A, "Caledonia" pattern, self-adjusting, one screw fastening the whole skate, the best principle, 6s. per pair. No. 8, Metal frame, with strap complete, 1s. 9d. per pair; postage, 5d. per pair. These are not rubbish; we warrant every pair.

NEW CATALOGUES of Machines, Designs, Wood, Tools, etc., with 600 Illustrations and full instructions for Fret-cutting, Polishing, and Varnishing, price 4d., post free. A Specimen 6d. Fretwork Design **SENT GRATIS** with each Catalogue; also a List of Designs, Outfits, Tool Chests, etc., at Greatly Reduced Prices to clear.

N.B.—All orders *must* be accompanied by remittance. APPLY—

## BOOT AND SHOE REPAIRING.

BY WILLIAM GREENFIELD.

### SOLING AND HEELING.

INTRODUCTION—COMPARATIVE COST OF LEATHER—GRINDERY, ETC.—THE SHARPENING STROP—TREATMENT OF LEATHER—PREPARING THE BOOTS—SOLING—HEELING—PRICE LIST OF TOOLS, ETC.

IN bringing these and the following articles under the notice of the readers of WORK, I do not think I am far wrong when I say there are a great many skilled workmen, of various trades, who read the many very interesting articles that are given us simply to gain an universal knowledge, as they do not touch their own particular trade farther than suggesting an idea or two, and therefore (although very edifying) they get but the theory, as they cannot experiment upon them, for want of spare cash as means to provide themselves with tools, materials, etc. But this can form no excuse for not putting these articles on Boot and Shoe Repairing into practice, for there are not many tools needed to start with, and leather can be bought in small quantities, and all the necessary grindery (rivets, brads, pegs, wax, hemp, paste, etc., etc.) can be bought, not only in small quantities, but at a very low rate; and last, but certainly not least, that which you are about to produce is a very great necessity, and if you do not do it yourself, you must pay to have it done; for boots and shoes are not only a luxury, but a necessity. Therefore, if a man makes this trade a study as an amateur, he at once increases his income—at least, equivalent to it; for shoe leather is like rent—to keep yourself dry and free from exposure. It is a continual outlay, and thus makes a diminution in your wages, which is often keenly felt if you have a family.

Now, this expense can be obviated by any man of ordinary ability, and he can save himself a considerable item of enforced expense.

For, in the first place, suppose your boots want soling and heeling, the cheapest you can get them done for is 2s. 6d.,

gentlemen's; and then they are done in a very inferior manner, and foreign leather nearly always used—not but what there are good tannages and parts in foreign stuff. But this class of repairer only uses what are called first-cuts (the neck end of the butt), which is the lightest leather, both in substance and weight, and consequently the cheapest. Well, a pair of soles of this kind only cost about 4d. or 5d., the top-pieces (heel-pieces) 1½d. or 2d.; so really the leather does not cost more than 7d. at the outside; so if they do not last long in wear, it is not to be wondered at. Besides, they are often put on so badly, and with such long rivets, that you cannot get the sole off again without pulling them all to pieces. But if you do them yourself, and take pains with them, you are sure to get enough wear out of them to well recompense you for the time and money you have spent upon them.

Now, if you are going to sole and heel a pair of boots, a pair of soles of English tannage will cost from 9d., and top-pieces from 3d.; iron rivets, ½ lb., 1½d. (you can buy a halfpennyworth): ½ in. is a very useful size; sand-paper, 1 sheet, size 1½, cost ½d., and ink, ½d. Then you have about 1s. 4d. left towards tools, and a better sole you would not have got, at a good many shops, had you paid 3s. 6d.

Most important in tools, and most needed, are an iron foot, a hammer, knife, nippers, glazing iron, and rasp (a price list of which I will give later on). This stipulation of tools is, of course, not sufficient to turn work out properly. But my aim is to say the least quantity possible, so that the first four or five jobs shall cost no more than if you had taken them to an ordinary repairer to have them done. Perhaps it is well to mention here that heeling, underlaying (that is, pieces under the soles), is better to start upon than soling and heeling throughout; as by this means you will gradually get the use of the tools, and your hand in for harder tasks.

Say, for instance, your boots want the heels set up on one side only, and the soles want a piece under the side, or toe-piece. This is often the case, and you can do a job like this with very few tools. But, of course, always buy a tool if you want it, and can afford it; and always try and do the work as well as you can, for it is work that, if you do take pains with, you will soon see you are making progress. As it is work that has come under every man's notice (when he has had to pay for it), he has some idea how it should look when finished.

One indispensable tool is a sharpening strop. You can buy one, which is generally a piece of square wood, solid, about 16 in. long, shaped at one end for about 4 in. to form the handle, or you can make one out of any piece of wood yourself. But while you are about it, you may as well make a good and useful one, in this way. Take four pieces of wood, ¼ in. thick, 12 in. long, and about 1¾ in. wide: place them together in a square, as A, A, A, A, Fig. 1A, and screw them together as B, B, B, B, Fig. 1A. Then cut a square piece, as C, and fix it in with two French nails at each side, as D, D, Fig. 1A. Then have a square piece, the same substance, about 6 in. long, and shape it for the handle, as A, Fig. 1, leaving about 2 in. square, to form a stopper for the square case, which you will always find very handy to keep your spare awls in, and also broken awls, the use of which I will explain later on. It is also very good to keep your sharp knife in, for if left with other tools, it gets blunt, and when you pick one tool up, you are apt to cut your hand if the knife is close to it.

When you have got it completed, as Fig. 1, paste a piece of leather on one side, and on the other three sides paste emery-cloth, sizes 1½, 1, and FF. For a fine edge to the knife use the FF, and dip the blade of the knife in water, and finish on the leather side. In sharpening a knife, always hold the blade quite flat on the sharpener, or you will get a round edge to it, and make it very hard to use.

Now, paste is very often wanted. You can get a halfpennyworth at any grindery shop. But then some of it is sure to be wasted, as it so soon gets dry. So the best way is to get a little rye-flour—a table-spoonful put into a jar, with a little *boiling* water on it, and well stirred, is economical, and you can always have paste in a few minutes.

Well, now you have leather and tools, we will start work. The chair you sit on wants to be cut down, if an ordinary chair, to about 14 in.; or anything that height will do. Your tools, for the time, can be put on the floor, or on the box you keep them in (later on I will describe the way to make a shoemaker's bench). But now we will sole and heel a pair of boots. We will suppose them to be riveted or machine-sewn, and the new soles to be riveted on; or, if hand-sewn, they must be clumped (a new sole on top of the old one), though I hope you will soon be able to sew a pair of soles on, and then they need not be clumped. Then, first of all, dip the boots into water—the soles and heels only—and hold them in for a few minutes; then let them get dry a little, so as to let them be just mellow. The leather must be put in water, and let get thoroughly wet through: take it out, and let it get nearly dry—not by the fire, if you can help it. If you do, do not put it close. Then rasp off all flesh (a rough flaky stuff on the back); then put the lap iron (a laundress's iron with the handle off) on your thighs, just above your knees, put the leather on it, grain side down, and hammer it well out even and gently, commencing from the centre. This makes the fibrous tissues more dense, and makes it more resistive of wear, and also more impervious to dampness and water in wear. But while your leather dries, take off the old top-pieces that are worn, and if the lifts are worn, cut or saw them through the centre, and take away that portion that is worn (as *a*, Fig. 2). This can then be replaced by a piece of new leather, which need not be of the best quality. There are other forms of building up heels, which I will explain as we make progress.

Now take off the old sole. This should be cut off to within about ¾ in. from where the new sole is coming down to. You can then mark it off at the exact distance or length that you are going to have the sole, and then start to skive it off from this mark in a tapered form to where you have cut it off. Then take your knife, and from the line scoop it out evenly, until you get about one-third of the way through (as A, in Fig. 3). Then tap it down lightly, right across where you have hollowed it out; this should be done with the pane end of the hammer. This hardens it to receive the pegs or rivets, and gives an extra drop to receive the new sole without weakening the old leather. Where the sole is going to be spliced to this part of the waist of the boot it must be skived, but not too thin, and this is best on the flesh side for light work, and on the grain side for heavier work. Then slightly paste the groove in the old leather, and the new sole also, where it has been skived; this tends to make the graft nice and firm when finished.

It is well to mention here, perhaps, that it is all important to properly work the leather before using—that is, wetting, fleshing, drying, and hammering, as explained above.

Then place the boot or shoe on an iron foot. The sole should be put on (the skived end) to overlap the groove about ⅛ in (as A, in Fig. 4), which, when riveted, should be well into the groove (as shown at A, Fig. 5). If the graft is well done, it will have the end of the new sole sticking up above the old leather. This must be pared off neatly with the waist, then paned and rasped off; and if these details are carried out, you will not only have a neat, but a permanently solid seam (as A, Fig. 6).

Now, before putting the rivets in, pare up the sole, but not too close—leave a small margin all round. About ⅜ in. from the edge, draw a line all round with a pair of compasses; if you have not a pair, hold a pencil between the thumb and finger, placing the second finger against the edge of the sole, which will answer the purpose. Then with an awl prick all round the sole, on the line, small holes to receive the rivets. The best way is to put them close where the most wear comes—that is, generally, at the toe and outside joint. Where it is best to use iron, and elsewhere brass, rivets, Fig. 7 shows about the form in which they should be put in.

Then, again, trim up the edge with the knife, being very careful not to cut the tops; then damp the edge, and pane it all round with the pane end of the hammer. This should be done with the shoe on the knees, with the heel towards you and the edge of the sole upwards, as shown in Fig. 8, and paned as shown at A B, same figure, commencing at A, and going right round the sole. This paning process is important, as it hardens the edge, tends to make it hollow, and prepares it to receive the next tool, which is the rasp. Fig. 9 shows the toe end of a shoe, and shows how this paning should be done to pane the new and old leather together, and keep the edge hollow (as at A, Fig. 9). Then let it dry, while you proceed with the rest. If you have had to repair the lifts (which you ought not to do, for when you repair your own boots, never let the heels go more than just through the top-piece: then you keep the heels in shape), in putting the pieces on, do not let the nails be too near the edge, or, when you put on the top-piece, one set of nails will come in contact with the other, and produce very unpleasant results. When you build the heel up, ready for the top-piece, it is well to make that side where the most wear is just a little higher—it tends to make you wear more even. Then tack your top-piece on, putting a nail at A and one at B (Fig. 10), and round it up with the knife, leaving a little on all round, more particularly the part that is to receive the most nails, as shown by the dotted line, Fig. 10. The rivets should then be put in, as C, C, but first mark it round and hole it, as you did for the soles, then pare and pane, as described above; then the edges of the soles and heels should be rasped, then buffed with a buff-knife (or scraper, as it is also called). This tool can be made with about 3 in. of old stay busk; the way to make and sharpen it is very well described in Work, No. 24, Vol. I., pages 372 and 373, in an article on the Scraper, by A Cabinet-Maker. Such a tool can be

bought, but it is seldom ready for use, so you might as well make one right out; a piece of glass, fresh broken, will suffice. Then sand-paper the edges with a piece of 1½ sand-paper. Then the tops of the sole and heel can be filed with the file side of the rasp, to make the heads of the rivets smooth and even with the sole; then buff off the grain of the leather with the scraper, and sand-paper it all over. This is called a rough bottom, and all that is needed for own work. Now you can rub just a little paste on the edges with a piece of rag, and ink the edges and the waist (American ink is best). This you let get just dry, then iron them up with the glazing-iron. The iron must not be very hot; its proper heat can be told in this way—that is, if it is put into water, by it only being hot enough for it to just cause a frizzle. A forepart iron should be used for the soles, but the glazer will do for the trial. This ironing process gives a nice gloss, which is increased and made more permanent by ironing a second time, at the same time ironing on a thin coat of heel-ball, which can be rubbed off smooth with a piece of old cloth, which will leave a brilliant polish.

But before I leave this, our first job of soling and heeling, I must tell you I always want you to bear in mind the following: that you can finish any job in repairing much better if you have a last inside; and that paning, rasping, buffing—in fact, all finishing—should be commenced from A for the soles (Fig. 8), and from B (Fig. 6) for the heels, the only exception being in using the knife, the action of which is just the reverse in both cases; that you should get as many tools as you can, but not till you want them, and always use them for their proper purposes; and last, that I shall always try and be as explicit as possible in describing the terms, tools, and means, so as not to lead the student into any mystery that will cause him to lose his patience.

I may briefly state that an iron foot may be bought at 1½d. per lb., and a handle for 5d.; or a Paragon foot (Blakey's) may be purchased for 1s. A shoemaker's knife costs 2½d.; a hammer, 6d.; nippers, 5½d.; glazing-iron, 6d.; and a forepart iron, 8d. These may be obtained at any grindery shop; but if any reader is unable to find, or pay a visit to, any such shop, he may get the tools named, and any others commonly used in the trade, at Penton's, 1 and 3, Mortimer Street, London, W.

## ARTISTIC LITHOGRAPHY.

BY MISS ADA J. ABRAHAM.

TRACERS—SCRAPERS AND ENGRAVERS—POINTERS AND GRAVERS—SNAKE-STONE—PUMICE-STONE—TRACING PAPERS—DIAPHANIE—KEY-STONE—HOW TO USE THE PEN—GELATINE—RED TRANSFER PAPER—NITRIC ACID—ETCHING—GUM FOR PREPARING ACID—ACETIC ACID—BENZOLINE.

TRACERS are best made of small round pieces of steel, about as thick as the lead of an ordinary pencil, and about 1½ in. in length, fixed in a wooden holder, and pointed just sharp enough not to scratch or tear the tracing. A hard lead pencil may be sometimes used, but the point wears thick and does not make such a clean line.

Scrapers and engravers are steel knives thick in the centre, bevelled off on either side, and made very sharp at the edges. They are of various sizes, and used for cutting lines on the stone, or making corrections, etc. A sharp penknife is sometimes useful if handled with discretion.

Pointers and gravers are round or square pieces of steel, fixed in wood like a lead pencil, and sharpened to a very fine point or a flat surface. Should the student require one finer than can be bought, he could take an ordinary tailor's needle, fix it in a wooden handle with sealing-wax, and sharpen the point to the size required. It is well to have various sizes for different kinds of work, and a hone or oil-stone should be kept for the purpose of sharpening penknives, pointers, etc. Of course everyone will know that this cannot be used without a little common oil.

A small stick of water of Ayr, or snake-stone, should be kept for the purpose of repolishing any small portion of the stone without going to the printer; this must be used with water, and the stone rinsed well afterwards with a clean sponge and water.

A piece of prepared pumice-stone will answer the same purpose as snake-stone, and has the advantage that it need not be used with water, simply scraping it clean with a knife; but it is better to use snake-stone when the water would not interfere with the drawing.

The artist must always bear in mind never to work on the stone while it is wet, or the damp surface will cause the water from the ink to spread, and so destroy its properties. Should the breath of the artist go on the stone it would have the same effect; thus he should protect the drawing by holding a sheet of paper or a protector before the mouth if he is obliged to look very closely at his work.

Various kinds of tracing papers are used in lithography; first the ordinary kind, which can be drawn on with an H or HH pencil, ordinary writing, or lithographic ink, a good clear pencil line being about the best.

French *végétal* tracing paper is much clearer than the ordinary kind, but having a shiny surface will not take the pencil readily. Lithographic pens and ordinary writing ink make very good tracings on this paper.

Then there is a specially prepared transparent paper called diaphanie, used for tracing drawings for colour work, or where more than one impression or tracing of the same sketch is required to be taken.

For instance, a drawing containing half a dozen different colours would necessitate half a dozen different stones, therefore six different tracings would be necessary; but it being impossible to make so many *exactly similar* tracings, the artist makes *one* on the above paper in lithographic ink, and then hands it over to the printer. This tracing the printer transfers to a stone called the key-stone, from which he prints as many different impressions as there are colours in the drawing—in the above instance six—and transfers them to the different stones, using red chalk in the place of ink, thus obtaining six perfectly similar red impressions from the one original.

It is difficult to know where to draw the line between the artist's and the printer's work; but it is absolutely necessary that the former should know a little of the subsequent treatment his work undergoes after it leaves his hands, and also that he should thoroughly understand and appreciate the different purposes for which any point connected with the drawing is required.

Care must be used in making the above tracing to do so on the prepared side of the paper; and this is important, insomuch that unnecessary delay may be caused by carelessness in this respect, in having the entire tracing to redraw. The prepared side is found by slightly wetting the finger and thumb, and pressing a corner of the paper between them; then whichever holds most firmly to the paper will be the right side on which to make the tracing. As a rule, the maker's name reads correctly on the wrong side, but the student will understand that this should in no instance be depended upon.

The above papers must not be confounded with the prepared papers previously alluded to, as they are only suitable for making tracings on, whereas finished drawings and writings can be made on the former.

Gelatine is also a very clear substance on which to make tracings or engravings, but more suitable for the graver than the pen. When the tracing is required to be engraved, as in the case of fine work, the lines should be cut cleanly out with a fine pointer—not too deep, but just sufficiently so to take a piece out of the gelatine, which will eventually be filled with ink and transferred to stone. It would not be of any use merely to scratch the surface, as it would not then hold the ink; and care should be taken to brush the pieces cut out cleanly away, or they will smear the lines.

When the pen is used it should be allowed to glide over the surface, and not dug into the gelatine. This applies as well to diaphanie paper, for if pressed in the surface the pen is likely to take the preparation or coating off from the paper, and will not make a clear line, which is so necessary to produce a good tracing; and whilst on this subject, the student will do well to remember that a little extra time spent over the tracing will save him double, nay treble, the labour in finding out the different parts of the drawing, especially in colour-work when it comes to be reversed on stone.

Although gelatine is so very clear, still the artist will find that for all ordinary work diaphanie paper will serve his purpose the best; and if gelatine is necessary for some fine and intricate kinds of work, it may be more worth his while to draw the tracing with the pen than to spend time practising with the graver, though of course it would be as well that he should know this, as well as every branch appertaining to lithographic drawing and engraving. It would be impossible to give details of all the different branches of lithography, which at times apply as much to the artist as the printer; therefore these subjects in future will only be mentioned so far as they are necessary for the furtherance of the lithographic student's work, in the reproduction from an original sketch or design on stone.

Red transfer paper is required for laying down the tracings already made on to the stone when it is only required to be drawn in one colour.

To make this paper, take a sheet of white tissue paper, and rub powdered red chalk upon it with the palm of the hand, putting it on with a circular motion, so as not to make holes in the paper, and also laying it on as evenly as possible. Red chalk is preferable to black, as the drawing being in the latter colour, the outline or tracing is more easily distinguished from it. Should there be too much chalk on the paper, flick the back of it with the finger and thumb; this will remove the superfluous chalk without taking more off than is necessary. One sheet of this paper will last a considerable time, and is preferable to that which is bought.

Nitric acid is necessary for etching stones, and should always be kept in a glass-stoppered bottle, and marked poison. It is much better to buy small quantities at a time, as it evaporates and loses its strength.

Etching here must not be understood to mean the same as etching on copper, steel, etc., as it has quite the opposite effect on the stone; and it is really a mistake to so call it, but as it has become a trade expression it must be let stand.

After the drawing has been made the stone is required to be etched, otherwise subjected to a wash of nitric acid, diluted with gum, which eats into the stone everywhere excepting in those parts where the drawing has protected it. No matter how fine a line or dot is made with the lithographic ink it will still preserve the stone from the effects of the acid; thus when etching on copper is spoken of it is understood that the drawing is eaten out of it, whilst in the above instance the stone is eaten away in every part excepting where the drawing has been made, which is thus raised above the level of the stone to a degree imperceptible to the eye.

To prepare the acid for etching the stone, place a small quantity of gum arabic (and please use the best) in a glass jar, and pour hot water over it, letting it dissolve; this should be made at least a day before it is required for use, and only small quantities made at a time, as it will not keep good any length of time, especially in warm weather, and nothing would be so detrimental as to use sour gum, which would eventually turn the stone mouldy and damp, thus spoiling the work.

The gum should be made just thin enough to allow it to pass through a fine strainer or a coarse piece of muslin, and should be strained into a flat dish or basin (a common earthenware pie-dish is as good as anything), after which pour some drops of nitric acid in the dish, according to the quantity required. To test if it is of the required strength, mix it well with a small brush, and try it on the edge of the stone; if it boils with a bubbling sound it is too strong, *i.e.*, there is too much acid for the quantity of gum; if it just boils—that is, if it froths on the stone—it is about right; but if it does not boil there is not enough acid in it. Another test is to taste, but not to swallow it, when it should have a sharp taste like vinegar or a strong lemon.

Acetic acid is used for preparing the stone should any alterations be necessary after the drawing has been completed and etched. Thus, if a drop of gum be on the stone, before any work could be drawn on that part, it would have to be washed off with pure water, then with a drop or two of acetic acid diluted with water, which should be allowed to remain on the stone for a few seconds, after which again wash it with a clean sponge.

Benzoline may be used to clean the stone after the drawing has been made, and before it is etched, and if used with discretion a tint may be made with safety over any portion which has been thus cleaned, provided the stone is not smeary, and that it is allowed thoroughly to dry first.

The above are the principal materials required in lithographic drawing. Any incidental ones which are not included will be duly mentioned; as they are required, in future papers on this subject; but for the present enough has been said on all things that are absolutely needed, at the commencement, by any intending lithographer, to enable him or her, as the case may be, to make a fair start.

## FIXING GLASS IN FURNITURE.

BY D. DENNING.

Classification—Fitting Plain Mirror—Various Rabbets met with—Protecting Back of Glass—Blacking Edges—Fitting Plain Transparent Plates—Fitting Bevelled Plates—Explanation of "Sight" Size—Templates—Fastening in—Preparing Blocks—Transparent Bevels—Faults and Defects in Glass.

For all practical purposes the glass with which the cabinet-maker has to deal in connection with the manufacture of furniture may be classified into four different kinds: viz., plain edged, silvered and transparent and bevelled edged, silvered and transparent.

Inasmuch as they are all plates of glass, it may be supposed that they are all fitted into furniture in the same manner, and that a method which will do for one of them will do equally well for the others. In a very modified sense this may be taken as being fairly correct, but the cabinet-maker or fitter who attempted to fit all plates alike could certainly not be regarded as a master of his craft, for there are little differences which require attention. The work necessary cannot be considered difficult, and I hope by the time the reader has studied this article he will have an intelligent appreciation of what to do, and how to do it, whenever he wants to measure and fix a piece of glass in furniture. Presuming that a previous article entitled "Furniture and its Glass" has been read by those interested, we may at once proceed to take up sundry cases which are likely to occur.

Fitting a piece of plain edged silvered plate, *i.e.*, an ordinary mirror, may as well be the first supposed job to be taken up, not because it is necessarily the easiest, but for the very evident reason that we must begin somewhere. What we have first to do is to turn the framing to be glazed face downwards on a table or bench of convenient height, taking the precaution, especially if the wood has been polished, to have a piece of baize or similar material under the frame. If the back board is on, it must be removed, and it will be just as well to note whether this is laid on the back or fitted within the rabbet, but for the present we may consider we are doing with a back laid on the framing, and consequently larger than the opening for the glass. The back being off, we may as well look at the rabbet, not like owls, but like intelligent reasonable beings. If we do, we shall probably find that it is like one or other of the following diagrams, which may be taken as typical of the principal variations one is likely to meet with. The diagrams it may be well to explain represent in section the immediate parts with which we are concerned, and are shown with both glass and back fitted. The various portions will be recognised without difficulty.

In Fig. 1 we have a deep rabbet, but not a particularly wide one—in fact, it is as nice and convenient as could be wished for. All that has to be done is to measure the full size of the rabbet and get the glass accordingly. It just fills up the space comfortably, so that there can be no movement laterally or perpendicularly when the frame is in its normal position, which may be taken as upright. There is, however, nothing to prevent the plate moving backwards and forwards between the back board and the front. It is therefore necessary to fasten the plate so that it will not be movable. This can very easily be done by putting blocks or strips of wood behind the glass. They are simply glued to the framing, and provided they do not interfere with the backing board, their size and shape are unimportant. They need not be continuous, as it will be quite sufficient if they are placed a few inches apart. A convenient length for each will be two or three inches. On no account be tempted to try and fasten the plate down with brads or nails in the way shown by Fig. 2 or any other way, the risk of injuring the glass being far too great to be run with any regard to prudence. It is sometimes done. If desired, however, there can be no harm in driving a small brad or wire nail in a similar manner through the block, which it will hold in the event of the glue giving way. Care, of course, must be taken not to let the nail come in contact with the glass, for if it does the edge of this is sure to be chipped.

Fig. 3 represents a shallower rabbet than Fig. 1, being just deep enough to receive the glass without any space, or none to speak of, for the blocks.

In this case it might be supposed that it is only necessary to fasten the back down, and if the plates are but small this simple means will do very well. It will, however, be better to put a layer of soft flannel or a sheet or two of soft paper by way of padding between the glass and the back. If the glass is silvered by the old process, some such precaution is absolutely necessary to prevent the silvering being damaged. The newer process does not require such delicate handling, but it might get injured by direct contact with the backing board, especially if this is either rough or panelled. Some old-fashioned people, I believe, still advocate the use of flannel behind the glass in all cases where it would have been used in the days when the old silvering process was universal. It is simply because such people are not quite awake to some of the advantages of the new process. With this the necessity for flannel is quite the exception.

Fig. 4 shows a rabbet both wide and deep. Remembering that there is no occasion for such a wide margin of glass as there would be were the space to be filled, it is optional whether we get the glass to fit exactly or not. Certainly if to make it a close fit would necessitate our running over a measurement of a full inch, and bringing in a fractional part of one, which, it will be remembered, will be reckoned on calculating the superficial measurement as a full inch, we will just take a fair amount to go behind the rabbet. This leaves a vacant space both at the edge and behind the glass, which is free to be moved in any direction. We must therefore fasten it in by blocks which bind in both directions, as will be easily perceived from the illustration. If the space is too wide for the triangular-shaped block to wedge the glass down, the section of the block can easily be altered to that shown in Fig. 5.

In Fig. 6 we have a wide rabbet, as in the last instance, but a shallow one so that the wedge-shaped blocks cannot well be used. It is therefore necessary to use those of rectangular section, which, it is very possible, may not require any gluing in, as the glass and backing board will hold them. Now, it must be evident to anyone that if we have a back board fitted within the rabbet, as shown in Fig. 7, instead of as in former instances outside that, the available depth for the wedges is much curtailed. The methods to be adopted for fixing are, however, the same.

The following general directions should be noted. Blacken the inside of the rabbet against which the face of the glass rests, and

also blacken the edges of the glass—which, by the way, will be more or less rough. If the blacking be omitted the reflection of the wood will be unpleasantly visible, and the rough edges of the glass will reflect in an unsightly manner, unless they are an unusually long way within the rabbet. For blacking, nothing better than a mixture of size or weak glue, with some gas-black, can be used. Be careful not to let any glue get on to the back of the plate, but if any does accidentally get there, wipe it up directly. If allowed to harden, it may, in drying, very likely pull the silvering under it away from the glass, and leave an unsightly blemish.

Plain-edged transparent plates, such as are used in bookcase doors, may now engage our attention. It is clear—I mean the principle, not the glass—that wedges or blocks cannot be used, for there is no back panel with which to hide them. The glass, therefore, must fit as accurately as possible to the rabbet, where it is held by strips of beading, as shown in Fig. 8, which, after what has been said, can require no comment to render it intelligible. If, as will sometimes happen in spite of all ordinary precautions, the glass does not fit quite so tightly as it should, the only way is to put thin strips of wood in a somewhat similar fashion to that shown by Fig. 9, taking care that they are covered by this beading. This should be neatly fitted and mitred at the corners. The strips should be long enough not to require jointing except at the mitred corners. The beads may be fastened down with glue, which, however, is not a method to be altogether recommended, as in the event of a broken glass it is impossible to remove without destroying them. They may also be secured with wire nails or brads, but a much neater way is to use small brass screws with rounded heads. Instead of beads, the glass may be fastened in with putty, a method which I cannot recommend, as it seems to me to be a slovenly way of finishing off cabinet work. Those who prefer it will have no difficulty in finding out what is necessary without instructions from me.

The fixing of bevelled edged plates may now be attended to; but before doing so, it will be as well to say something about measuring for them, in order that there may be sufficient glass behind the rabbet to hold the plate securely, without too much of the bevel being hidden, for we have now not only to consider the cost of the glass, but also of the bevel—the latter of which, it will be remembered, depends on its width. Therefore, our object should be to hide as little of it behind the wood as possible—consistently, of course, with safety to the plate. Careless or thoughtless people have been known to argue that the more glass there is behind the rabbet, the more secure the plate will be, but this is not correct, as the diagrams (Figs. 10 and 11) will serve to explain. In Fig. 10 we have a bevelled plate with a very narrow margin behind the rabbet, and in Fig. 11 the same with a very much wider one. Now, on looking at these it is at once evident that the glass, being bevelled, is in contact only with the extreme edge of the rabbet, and does not lie flat against the bottom, as in the case of plain-edged plates. It is therefore unnecessary to have more than just enough glass to hold within the rabbet, and $\frac{1}{8}$ in. is generally deemed sufficient. Less may do occasionally, but cannot be recommended, and a safe rule to follow is to order the plate $\frac{3}{8}$ in. larger than "sight" size. Thus, if the "sight" size is $23\frac{5}{8}$ in. by $20\frac{1}{8}$ in., order a plate 24 in. by $20\frac{1}{2}$ in. This allows $\frac{3}{16}$ in. surplus at each edge, but then the edge is seldom perfectly regular, and this extra $\frac{1}{16}$ in. must be allowed as a waste margin for irregularities in cutting the glass.

As the term sight size may not convey much meaning to some, though it is a term well understood by those acquainted with the work under consideration, it may be advisable to explain it. Briefly, it means neither more nor less than the surface of the glass which is visible from the front when the plate is in position and fixed—that is to say, the whole of the plate, with the exception of that portion of it which is concealed by the rabbet. When a bevelled plate is ordered, it is not at all an uncommon thing to simply order it according to sight size, and leave the dealer to allow the necessary margin. It is better, in any case, to state whether the measurement named is "sight" or "plate" size, in order that there may be no mistake. If, under such circumstances, the dealer makes a mistake, the loss is his own. For irregular or fancy shaped plates, it is best to get the glass cut from a template. This can easily be made by cutting a thin board, or several of them joined together, to

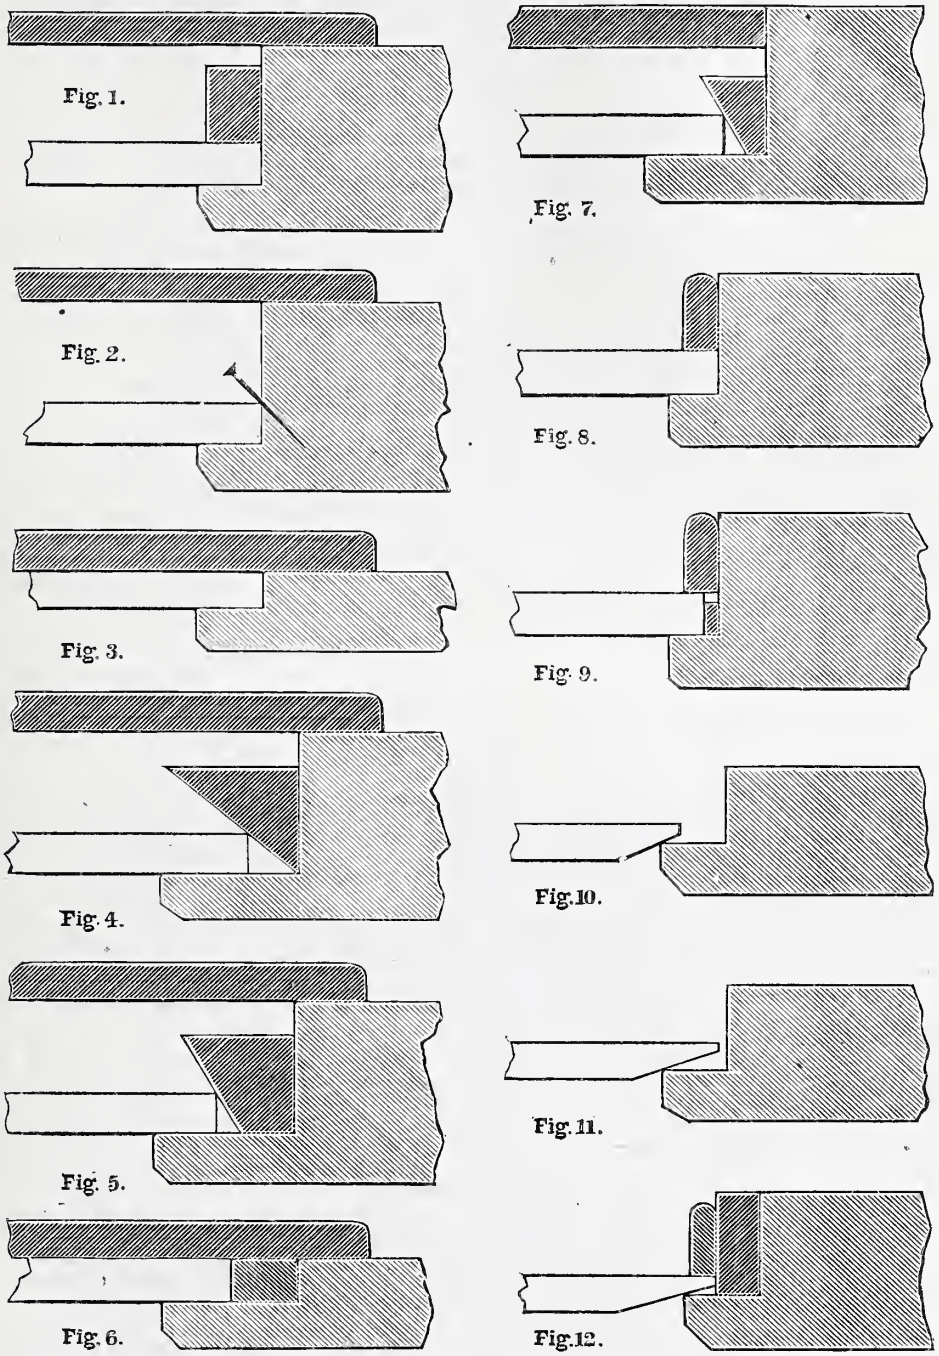

**Fig. 1.—Plain Silvered Glass in Deep Rebate. Fig. 2.—Ditto wrongly fastened. Fig. 3.—Shallow Rebate. Fig. 4.—Wide and Deep Rebate. Fig. 5.—Ditto with differently shaped Block. Fig. 6.—Shallow Wide Rebate. Fig. 7.—Backing Board within Rebate. Fig. 8.—Transparent Glass beaded in. Fig. 9.—Loose-fitting Transparent Glass blocked and beaded in. Fig. 10.—Bevelled Glass with little behind Rebate. Fig. 11.—Ditto with too much. Fig. 12.—Frame for Bevelled Transparent Plate with Rebate partially filled up.**

fit in the rabbet, and marking the sight size with a pencil. If the baeking board is made to fit within the rabbet, a simpler plan is to draw the template on a sheet of paper, which can easily be stretched on the board. Such templates will, of course, give the exact sight size, but it is best to state on them distinctly that the lines give "sight."

When it is practicable, frames to be glazed with bevelled silvered plates should, instead of being laid on a table or bench, be supported on trestles, so that the worker by looking underneath may be able to see that the glass is laid to show an equal width of bevel all round, and that the mitres fit accurately to the eorners of the framing. It will easily be understood that without care faulty fitting in these respects may result. With small plates there is seldom much difficulty, but as the size increases so will the need for more care. Let me here caution all whom it may concern not to attempt to alter the position of a plate by forcing it with a chisel, screwdriver, or other tool used as a lever. It is, unfortunately, no uncommon thing in some shops to see a man trying to foree a plate into position by this means. Sometimes he effects what he intends, and sometimes he damages the plate, especially if it is a large heavy one. All the movement necessary to get a plate exactly into its right position can be got by giving the edge of the framing a few light blows with the hand. The remarks which have been made about plain-edged plates are, on the whole, applicable to those with bevelled edges. When fitting these in, however, it will be found in the majority of cases that blocks, as shown in Figs. 4, 5, and 7, are the most suitable.

The best plan when working is, first, to get the plate into its proper place, then, being careful not to disturb it, fit the blocks in dry—*i.e.*, without glue. After they are placed, see that the position of the glass has not been accidentally altered. If it seems all right, proceed to glue down the blocks. It is not always necessary to blacken the edges and inside of the rabbet in the ease of bevelled plates as in plain ones; still, no harm can result from doing so.

The blocks which are needed do not require to be of very high finish, and seldom are so. It is no use wasting time over them. I have known large quantities of them prepared in the following manner. A board of 1 in. pine of straight even grain is taken. A piece about two inches wide is sawn from one end across the grain. From this the blocks are shaped by splitting it up into square pieces first, and each of these diagonally afterwards with a knife or ehisel. They may not look very elegant, but they serve their purpose; so what more ean be required?

Bevelled transparent plates are fixed in a similar manner to those with plain edges, but the rabbet should be only a narrow one. This can easily be arranged when making the frame, if it is then known that the plate is to be bevelled. If the rabbet is too wide it will generally be better to reduce it to the proper dimensions by gluing continuous strips of wood, as suggested by Fig. 12, than to waste money by having a wider bevel.

It will occasionally happen when a plate to exactly fill an opening is got, that the glass, through some irregularity at the edge, will not quite enter. In such a case a little judicious paring away of the obstructing wood with a chisel will often do all that is necessary, and is much more satisfactory than trying to chip the glass itself to make it fit.

Some discretion is often advisable in selecting which shall be the top or bottom of a piece of glass when it is fixed. For instance, we have, let us say, an oblong piece, one end of which will be high up, where it cannot be closely inspected, while the other will be where every defect is conspicuous. Naturally, it will be better to fix the glass so that its worst end, if there is any difference, will be at the top. I am not wrong when I say that cabinet-makers have been known simply to reverse the position of a plate supposed to be defective—perhaps actually so—instead of replacing it by a new one. The defect has been put where it is not so easily seen: that is all; the results have been perfectly satisfactory. The chief blemishes found on silvered plates are scratches on the metal or glass, water stains caused during the silvering, and small round bubbles or seeds in the glass itself. To all intents and purposes, it is impossible to get an absolutely perfect piece of glass of any size; though it may be sufficiently good for all purposes it will not stand the very minute inspection which some bestow on it. The scratches which are visible on a really excellent piece of bevelled silvered plate when it is held in broad daylight to reflect light direct from the sky are something to alarm the novice. In conclusion, I have only to say to purchasers of glass that before finding fault with any sold to them, it will be as well to take the opinion of someone who knows the material as to its quality, and that I trust the novice will find the foregoing hints sufficient to enable him to do whatever he may want in fitting glass to furniture.

## ELECTRO-SILVERING SMALL GOODS.

BY GEORGE EDWINSON BONNEY.

PREPARING THE SMALL GOODS—CLEANING—SCOURING—STRIPPING AND QUICKING THE GOODS—MAKING THE SILVER-PLATING SOLUTION—WORKING THE PLATING SOLUTION—FINISHING, POLISHING, AND BURNISHING SILVER-PLATED GOODS.

*Preparing the Small Goods.*—By small goods I mean the various little oddments which come to the counter of the country jeweller to be replated, such as alberts, charms, lockets, brooches, buckles, scarf-pins, rings, and one or two spoons or sugar-tongs. I should not advise undertaking the job of plating spoons and forks in dozens, nor anything larger than a dessert spoon, as larger articles demand more room than can be found in the small vat of a working jeweller, and more anode surface than he has at his command. More eare must be taken in the preparation of articles to be silver-plated than in the preparation of those to be electro-gilded. The hot solution of eyanide of gold will dissolve remaining traces of animal matter, but the cold solution of cyanide of silver has no such detergent effect on dirt left on the surfaces of goods intended to be silver-plated. We must, therefore, be sure to free the surface from the least trace of dirt of all kinds, whether in the form of rust, verdigris, tarnish, and any other form of corrosion, or in the form of oil, grease, lacquer, sweat, and other animal matter. The touch of a soiled finger on the prepared surface is sufficient to spoil it, and cause the silver to strip off from that spot when the scratch-brush or the burnisher is applied to it. All deep scratches, dents, cracks, and pits must be removed before the goods are re-plated; all necessary repairs must be done (and in doing these, avoid an excess of soft solder); all the previous coats of silver or of nickel must be removed, and the surface must be polished.

If the articles are free from eorrosion, but appear to be dirty from grease or oil, place them for a time in a boiling hot solution of caustic soda or caustie potash, then rinse them in hot water. It is always advisable to make this the first eourse of treatment, whatever may be their condition. If they appear to be lacquered, steep them for an hour or so in warm methylated spirit, then transfer them to a strong solution of ammonia, to loosen the lacquer. After such treatment, they should be well brushed with an old scratch-brush or bristle-brush, and rinsed in hot water. Use old brushes for this purpose, as it will not be advisable to use the same brushes for brushing the surfaces of finished goods. Tarnish may be removed by soaking for a short time in a strong solution of cyanide of potassium, to which has been added a few drops of liquid ammonia. Green verdigris and similar forms of corrosion may be removed by dipping in a mixture of equal parts sulphurie acid and water, to which is added half part nitric acid and a few drops of hydroehlorie acid. The articles should be strung on a wire, and swilled in the dipping mixture for a few minutes, until the corrosion has been loosened, then rinsed in plenty of elean water. After this, they may be brushed with an old scratch-brush, and again swilled iu water. If the verdigris is not all off, they must be again swilled in the acid pickle until quite clean.

Scratches on the backs of watch-cases and lockets, and pits left from corrosion in other articles, must be taken out with a fine file, then the file marks rubbed out by grinding with water of Ayr stone, after which the surface should be scoured with a cork dipped in powdered pumice, then polished bright in the usual way. Spoons and forks should receive similar treatment. It is not necessary to be so particular in getting a very finely polished surface for silver-plating as for electro-gilding, since the coat of silver can be got up afterwards; but the same care will be needed to get an uniform surface, free from scratches and pits.

*Stripping the Silver Coating.*—All the old coat of silver, nickel, or gold must be stripped off before we can successfully deposit a new coat on the article. It sometimes happens that the plater fails to get an adherent coat iu his first attempt. If part of it strips off under the scratch-brush or the burnisher, the whole remaining part of the coat must also be stripped off by the following means: Get a vessel capable of heating and holding acid at boiling point, such as a porcelain evaporating dish or a stoneware pipkin. Pour into it enough strong sulphuric acid to cover the article about to be desilvered, and make the acid hot over a gas stove or oil stove on a sand bath. When the acid is hot, sling the article in a piece of copper wire, immerse it in the hot acid, and add a few erystals of saltpetre. These will dissolve, and give out just enough nitrie acid to dissolve some of the silver. Move the articles about in acid, and add more saltpetre, until all the silver has been dissolved off. If proper care is taken, all the silver may be stripped off without pitting the underlying surface of brass or of German silver. When quite free from silver, the surface must be rinsed in water, scratch-brushed, and prepared to receive a fresh coat of silver. If the artiele has been nickel-plated, it must be swilled in either the before-mentioned stripping acid or in a warm mixture of two parts sulphuric acid

and one part nitric acid, taking care, in both processes, not to keep the article in the acid longer than necessary to strip off all the nickel. It is most important to have the article dry before putting it in the stripping acid, to prevent irregular action. Gold may be stripped off in a warm mixture of nitric acid three parts, and water two parts, to which must be added, as required, a few crystals of common salt or a few drops of hydrochloric acid.

Articles made of pewter, lead, tin, Britannia metal, solder, or any other lead or tin alloy, may be entirely cleaned in the caustic solution, without the use of acid. Rust on iron or steel may be removed by soaking in dilute sulphuric acid, to which has been added a few drops of hydrochloric acid. Both this metal and alloys of tin and lead must be first coated with copper in an alkaline coppering bath (described in the last chapter) before they are placed in the plating vat to receive a coat of silver. In the case of iron and steel, this must be done promptly after cleaning, before a film of rust can form on their surfaces. Lead and tin, and other alloys, must be plated immediately after they are taken from the potash solution, without rinsing in water. Articles made of brass, German silver, and similar white or yellow alloys, receive a more adherent coat of silver when first coated with mercury in a solution of proto-nitrate of mercury in distilled water. To make this, dissolve a few drops of mercury slowly in a mixture of equal parts nitric acid and distilled water, using only enough acid to dissolve all the mercury, then dilute the whole to twenty times its bulk with distilled water. Swill the articles in this when they are ready for the plating bath, then rinse them in clean water. This is named "quicking" the articles.

*Making the Silver-Plating Solution.*—The solution for silver-plating is easily made. Get some pure re-crystallised nitrate of silver, in the proportion of four and a half ounces to each gallon of solution required. Also get ¼ lb. of 95 per cent. pure cyanide of potassium for each gallon of solution. To make one gallon of solution, dissolve the silver nitrate in half a gallon of distilled water in the glass vessel intended to serve as a vat, and half of the cyanide of potassium in one quart of distilled water. Add small portions of the cyanide solution to the nitrate of silver solution, and stir well with a clean stick between each addition of cyanide, until all the silver has been thrown down in the form of white curds, and a few drops of the cyanide solution fails to cause a white cloud in the silver nitrate liquid. When this condition has been achieved, pour off the useless liquid (which contains nitrate of potash), and pour a quantity of clean common water on the white precipitate. Allow this to stand for a few minutes, then pour it away, and repeat this some two or three times, finally draining off all the wash water from the silver cyanide precipitate. Dissolve the remaining cyanide of potassium in distilled water, and stir this into the wet precipitate of cyanide of silver until all has been dissolved. Then add one-fifth more cyanide, and make up the solution to one gallon with distilled water. This solution will be worked cold. For an anode, use a plate of absolutely pure silver having a surface area slightly larger than that of the largest article, or total area of the largest group of articles, likely to be plated in the vat. It is best to have an excessive surface of anode, as we can always draw out this to suit small surfaces being plated. If the anode does not dissolve cleanly and freely in the solution whilst at work, add some more cyanide in small quantities at a time.

*Working the Plating Solution.* — Each article must be hung to a long hook made of copper wire, and suspended by this in the solution whilst receiving its coat of silver. For very small articles this hook may be made of No. 28, whilst for larger articles it may be made of No. 20. This hook is made in the form of an **S**, the lower end hooking behind a pin, into a bow, into a link, or to some projecting part of the trinket. The articles should be wired with wet hands before the final dips, and not touched with the hands afterwards, but placed straight away in the plating solution, suspended to the cathode rod attached to the zinc of the battery. Two or three cells in series will be enough to force current through the wires and deposit the silver in good condition. The articles should be coated white with silver within a few minutes of placing them in the depositing vat. They should then be taken out and brushed with a clean scratch-brush in clean water, to test the adherence of the deposit. If this does not strip, the article must be rinsed in clean water, and restored to the vat to receive a finish coat. The time taken to do this will depend upon the price to be paid for plating, since a longer time in the vat represents a thicker coat of silver. By carefully weighing the article after it is polished, preparatory to plating, and weighing again when dried, after it has been plated, we can find out the weight of silver deposited upon it. A thick coat of good adherent silver may be deposited in two hours; but the time taken will always depend upon the condition of battery and solution, so I cannot lay down a fixed rule. I may say that for 6d. a trinket we can only afford a mere blush of silver over and above the scratch-brush coat, and this may be laid on in a few minutes.

*Finishing Electro-Plated Goods.*—When the articles are sufficiently coated with silver, disconnect the slinging wires from the cathode rod, swill the plated goods for a few seconds in the bath, then rinse them in hot water, and rub or bury them in hot boxwood sawdust until dry. Plain patterns may be rubbed dry with soft linen rags after being rinsed in hot water. When dry, brush out all sawdust from crevices with a soft brush, and proceed with the polishing processes. If only a thin film of silver has been deposited, as for whitening buttons, etc., rattle the articles about in sawdust, and brush them with a mop of soft rag charged with plate powder. If a thicker coat of silver has been deposited, and the deposit has a "matt" appearance—*i.e.*, creamy white, without lustre—it must be scratch-brushed until the "matt" surface gives place to one having a dull lustre. This must be done with a clean medium scratch-brush made of medium brass wire, using stale beer as a lubricant. If doing this by hand, rest the articles on a sloping strip of smooth wood in a tub or similar vessel, and use the brush in strokes away from the workman, to avoid splashing the beer over the clothes. Rinse each article in clean water, and dry again as before, either in hot boxwood sawdust or by rubbing with soft linen rags. By using a fine scratch-brush to finish off after brushing with the coarser brush, a tolerably good surface may be given to the plated goods, and this, when polished with a plate-brush, will suit customers better than the higher polish imparted by revolving mops and burnishers. The work of polishing can, however, be more expeditiously performed on a revolving mop or dolly in a polishing lathe than by hand with brushes. A very fine polish can be imparted to silver surfaces with rouge applied on a revolving calico mop, finishing off with a softer mop of swans'-down, and finally polishing with the palm of the hand.

*Burnishing.*—The highest polish is given by the process of burnishing — that is, rubbing the surface with burnishers made of polished steel or polished bloodstone. The burnishers are kept lubricated with freshly-made soapsuds, and the strokes of the burnisher are all given in one direction. When only small portions of a trinket have to be burnished, just to stand in relief to the rest of the surface, the burnisher may be a highly polished steel bodkin. It should be polished on a piece of buff leather charged with rouge. An illustrated article on "Burnishers and Burnishing" may be found in page 411, Vol. IL of WORK.

## MEANS, MODES, AND METHODS.

### To Stain Mahogany Port-Wine Colour.

Procure a little quicklime, and stir it up in water, making a kind of weak limewash. Apply this to the surface of the wood until you get the required tint; allow it to dry, glass-paper off, and polish in the usual manner.—F. C.

### Gold Paint, for Touching up Frames.

Mix together gold bronze and copper bronze to the desired shade; if required a rich deep colour, more copper; if lighter, more gold. Mix with Japan gold-size thinned with turpentine, just as much as is required for immediate use.—H. H.

### Fastening Corners of Gilt Frames.

These are nearly always nailed together, but if a really good job is desired, in which no nail-holes are to be seen or the gilt interfered with in any way, proceed as follows:—After shooting the mitres true and clean, bore from the inside of the mitre with a small quill-bit out to the back side, not out to the edge. Then sink with a gouge to admit a fine 1¼ in. or 1½ in. screw; put screw in position to mark where hole comes in the other mitre, bore with a sprig-bit, glue slightly, and screw down. If this is done clean and well, we have a firm joint, and nothing seen on either edge—a great desideratum in gilt frames.—H. H.

## WIRE-WORK IN ALL ITS BRANCHES.

BY JAMES SCOTT.

### Crimping Machines—Benches—Tools.

Two machines for crimping or corrugating wires of various gauges are shown in Figs. 5 and 5A respectively. That represented in Fig. 5 is used for small gauges of wire. I am not very well acquainted with the technical terms used in the iron trade; therefore, should I, during my descriptions of these machines, not use the accepted trade definitions, my readers must forgive me for my ignorance, although this want of knowledge on my part will not prevent me from giving proper explanations.

In Fig. 5 there is a thick standard, divided into two separate parts horizontally, as indicated by the cross line, and held together by a pair of screws, which penetrate sufficiently deep into the lower half of the

standard to afford the requisite strength, and whose heads are above the standards, as shown. On the front are two barrels, which receive the axles of the wheels. The latter are removable from the axles, and are held to them in such a manner as to prevent them rubbing against the standard, or slipping from the barrels, by washers, etc. Through the ends of each axle, opposite the wheels, is a removable pin to prevent the wheel and axle from being pulled out of its place accidentally.

In working, the wheels are brought sufficiently close to each other to receive the particular gauge of wire to be crimped by the perpendicular screws being turned. For various degrees of crimping, different pairs of wheels of the same diameter as each other are used, the cogs on each pair varying in thickness to those on the remainder, in order to secure long or short crimps, as the case may be. It is to allow all wheels to be properly fitted that the axles are made detachable from the barrels by removing the pin in the end of each.

The machine shown in Fig. 5A affords the same facilities as those gained from that in Fig. 5, the difference being that these wheels are used for stouter gauges of wire and larger crimps. Here the axles are supported by side standards at each end, in which fit square blocks (see view Fig. 6A) to receive the axle ends. The square blocks slide up and down the standards, and consequently carry with them the axles, wheels, etc., in order that a change of wheels can be made when required for purposes previously named. At the top of each standard is a cap, both caps being united by means of a cross-bar. Each cap is hinged at the back to a standard, and in front is removable, being held firmly, when desired, by means of a loose nut attached to a fixed screw, which latter penetrates through a hole in the cap.

For closing the wheels together there is an attachment at each side, shown separately in Fig. 6B. On the outside of top axle-block is a stout barrel, through which passes a movable screw-rod. In a similar manner, there is outside each lower block a barrel, into which is firmly imbedded a horizontal screw, which enters the screw-rod just alluded to. It should now be seen how the wheels can be brought to the requisite adjacency to each other by means of turning the side screw-rods over the side screws. I will now pass on to remarks on the benches and tools.

Simple benches only are used by wire-workers. There is, therefore, not the slightest necessity for me to give drawings of such. They are used in a great variety of sizes, according to the shape of the shop wherein they may be fixed.

Of the tools proper only a few are necessary. These are large shears (Fig. 6), hand shears (Fig. 7), nippers (Fig. 8), pliers (Fig. 9), vices, and hammers. There are several adjuncts, which, however, I prefer to term accessories, and shall describe in future papers, where I can deal more appropriately with them. The first of these tools is used for cutting up bundles of wires into required lengths, and for this purpose the shaft (C, Fig. 6) is fixed in a large vice and firmly secured, the cutting being done by working the handle pump-wise. The hand shears are used for similar operations when the wires to be cut are not so thick or strong as to require the aid of the large shears. The assistance of the pliers is called in for "turning over," and the nippers for "squeezing down" and clipping off superfluous ends of

wires. Hammers and vices need no commenting upon. The different processes previously named in connection with these tools will be described by me later on.

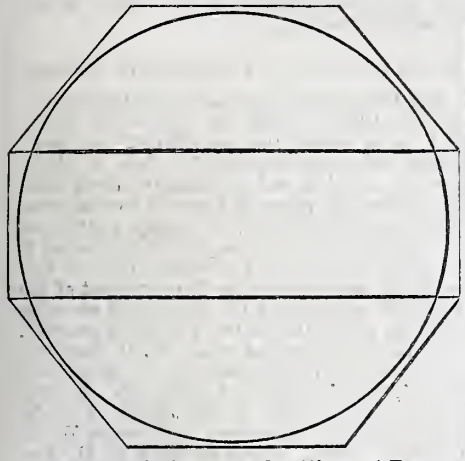

Fig. 1.—Jointing up and cutting out Top.

## HOW TO MAKE A ROUND TABLE.

BY H. HINGE.

METHOD OF CUTTING OUT TOPS—SETTING OUT—SADDLE FOR MORTISING LEGS—SHAPING RAILS—FRAMING UP—SECURING TOP, ETC.

A THREE-LEGGED round table appears at first sight a simple job, but if a man has never seen one made, or been instructed in the art of making one, he will find a difficulty in doing so unless he goes the right way to work and begins properly.

Where round tables are manufactured for sale, workmen generally get them to make by the dozen, and it is astonishing how quickly they can be made. The method generally adopted is as follows :—To begin with, the tops are jointed up ; these consist of three pieces of stuff, 9 or 11 in. wide (unless a special size is wanted), of dry, sound pine or deal; if 9 in. wide, the middle piece is cut off, 2 ft. 3 in. long; if 11 in. wide, 2 ft. 9 in. long, by laying another piece of stuff alongside the middle piece, and marking a circle with a trammel,

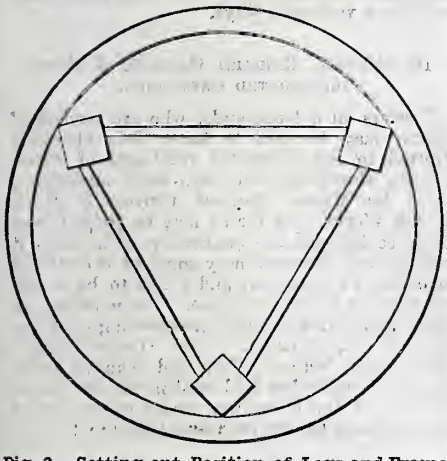

Fig. 2.—Setting out Position of Legs and Frame.

or some other means. It will be seen, by cutting the next length off on the bevel, and reversing the edge for the other piece, that a considerable quantity of wood can be saved in cutting out a lot of tops. Fig. 1 will explain the method of cutting out tops. The tops are seldom more than slip-jointed (shooting the edges straight with a plane, and gluing and rubbing). Of course, if a better class of thing is wanted, it can be grooved and tongued together, or dowelled. Now, to set out for the frame, we want a board as large as the top—the top will do very well if the joints are dry. Prepare it by planing it up on one side, and mark out the circle you want the top to finish, and then mark another circle $1\frac{1}{4}$ in. less, which will indicate the outside size of the frame. Divide this into three parts to form a triangle, and mark the size of the legs, keeping the square of the leg on the spot, as shown in Fig. 2. When all three squares are marked, it is only necessary to fill in the rails, letting them stand in from the outside of the legs as much as is necessary to give strength and room for the tenon. The frame is now "set out," from which we can get the lengths required for the rails, and the right bevel to mortise the legs. A bevel should now be set by laying the stock of the bevel along the line which indicates a rail, and the blade set to the angle of the leg. A piece of 3 in. scantling is now planed up square, say a foot long, and pre-

Fig. 6.—Round Table when finished.

pared by marking it with the bevel, and from the bevel a line taken up square (to receive the leg for mortising), the piece is cut out true to the lines, and we have what is called a saddle. Fig. 3 shows the saddle with a leg in ready for mortising. The legs are set out 2 ft. 4 in. or 2 ft. 5 in. high, and the breadth of the rail marked on it, allowing an inch from the extreme height of the leg for what is termed a hancheon, so that when the leg is sawed off level with the top of the rail the mortise will still be down an inch to give strength. When the leg is secured in the saddle, which is generally held firm by the bench holdfast, the chisel is held quite upright, and the mortises cut in the ordinary way. The rails are generally made of $\frac{3}{4}$ in. stuff, about $4\frac{1}{2}$ in. or 5 in. wide. The length we can get by measuring on our setting-out board, allowing it long enough for the tenons. When these are planed up and taken to a breadth, one of them is marked on the bottom edge for shaping, which generally takes the form of Fig. 4. All three are held together in the bench screw, and cut out with a bow-saw, and trimmed up with spokeshave or rasp, and all done that is necessary while in that position. If a quantity is being made, a templet, or pattern of thin wood, would be made to mark from. Care must be taken not to have the tenons too tight, or else they will split the legs, but yet fill nicely the flat way, and in the width be tight, as there is no danger of splitting that way. In setting out the rails, a shoulder is only made on one

Fig. 4.—Rail properly shaped and tenoned.

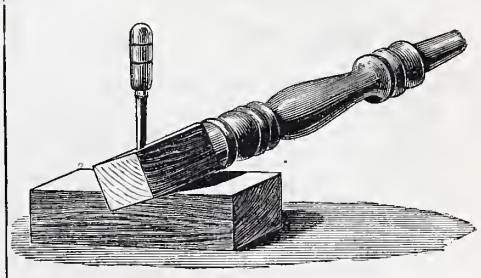

Fig. 3.—Saddle to hold Leg for mortising.

side (the inside), and, instead of being square, it is bevelled about a quarter of an inch, which will cause the legs to stand out when the table is framed up. The rails should be smoothed up and all done we consider necessary before the table is glued together ; it may be found necessary to use a cramp to get the joints up. All being on the bevel, it must be watched where it is pulling, or else it will do mischief. Blocks of wood should be fitted in the corners and glued in, which will greatly strengthen the frame. When the glue is set, the tops of the legs should be bevelled off with the frame and planed true. Sometimes pins, or dowels, are bored in the legs to keep the joints up, but a cabinet-maker would scorn the idea of ever putting dowels in to hold a tenon up. A rail about 3 in. wide and 1 in. thick should now be fitted across the frame to hold the top true. Fig. 5 shows the top of the frame with rail in. The rail is let down the thickness of itself to come level with the rails, and nailed down firmly. Holes are bored in this rail to receive some stout $1\frac{1}{4}$ in. screws to screw the top down.

The top is prepared by cutting round

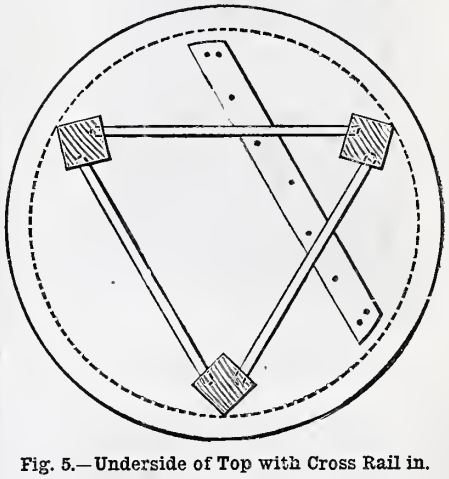

Fig. 5.—Underside of Top with Cross Rail in.

with a bow-saw, and cleaning up the edge with either spokeshave or sharp smoothing-plane, placing the best side down on the bench. The frame is placed on it in such a position that the flat rail comes across the joints of the top. It is now screwed firmly

down, and, placing it on its legs on the floor, the top is nailed to the other rails from the top side, and a good 2½ in. or 3 in. nail sent down into each leg. These are punched down with a punch well below the surface, to admit of the top being smoothed up with a sharp smoothing-plane, the sharp edges of top being taken off with a piece of coarse sand-paper. The top is sand-papered across the grain (a little white putty having previously been put in the nail-holes) till smooth and clean, and our round table is complete.

## OUR GUIDE TO GOOD THINGS.

**** Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

### 13.—Pitman's New "Demon" Water Motor.

Mr. P. Pitman, Aubrey Road, Withington, near Manchester, has sent me a prospcetus of his New "Demon" Water Motor, and a specimen of the smallest or No. 1 size for testing. The motor itself appears to be well made, and there is no fault whatever to find with it in this respect. The following are particulars of its dimensions, taken from Mr. Pitman's prospectus, in which all of these are stated to be approximate only:—Bore of pipe, ¼ in.; diameter of pulley, 2½ in.; weight, 24 lbs.; height, 9 in.; breadth, 8 in.; revolutions per minute at 60 lbs. pressure, 1,800; power, quarter man. Price, 25s.; regulator extra, 3s. The general description is as follows:—"Inside the motor is a drum, on the eircumference of which are several cams. The water entering by the supply pipe forces these cams to rotate, until each cam in turn comes opposite the exhaust pipe, when the waste water falls through the exhaust exit of its own weight. The mechanism is not subjected to severe shock; there is a steady and continuous outward impulse, and such changes in velocity as do occur balance each other exactly. The shaft and all wearing sur-

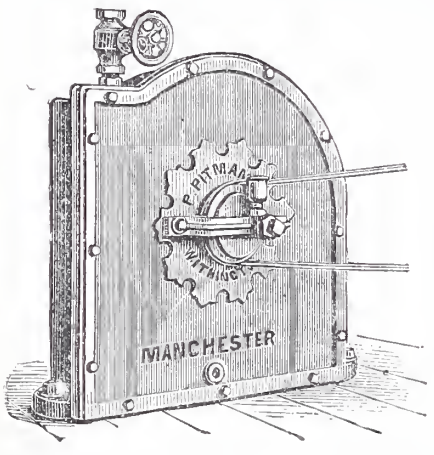

**Fig. 1.—Pitman's New "Demon" Water Motor.**

faces are of hardened steel, gun metal, and brass, and are fitted with oil cups and lock nuts. The pulley wheel may be removed and another of more suitable size put on in its place, or an additional wheel may be keyed on the opposite side, if found desirable. The working parts are boxed in a removable cover, being fitted to facilitate examination, etc., of the machinery." It is further claimed that "it is the cheapest and best motive power engine (both in first cost and when working) that has yet appeared;" and that "this engine is a most useful and economical motor for driving every description of small machinery; and is now thoroughly established as a success in the hands of practical users." Its appearance and construction are fairly shown in Fig. 1, which, it should be said, is from a photograph of No. 2 motor eomplete.

On receipt of the sample motor, I put it into the hands of a practical man for thorough testing, and the following is his report:—"In reading through the instructions for fitting in Mr. Pitman's circular, I notice that he says:—'When

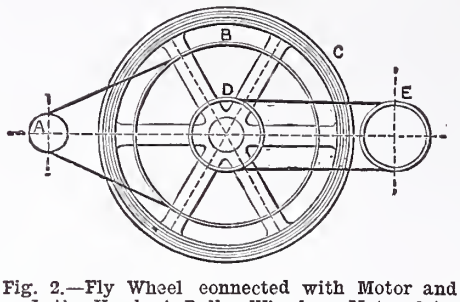

**Fig. 2.—Fly Wheel connected with Motor and Lathe Head—A, Pulley Wheel on Motor, 3 in. in diameter; B, Driving Wheel of Fly Wheel, diameter 18 in.; C, Heavy Rim of Fly Wheel, diameter 28 in.; D, Smallest Rim of Fly Wheel, diameter 6 in.; E, Pulley Rim on Lathe, diameter 6 in.**

feasible, I recommend, as the most economical method of driving, that the power be conveyed direct from the motor by belt or rope, *without* the intervention of countershafts or separate gearing.' I understand this to mean to save power, not expense. I therefore connected motor to water supply, and ran a small gut direct to pulley of lathe head. The power and speed given off were so small that when I placed a piece of wood to the ¼ in. drill which was in the lathe, the motor immediately stopped.

"Now I entirely disagree with Mr. Pitman's idea of driving, as the above and what follows will show. If he knows anything of the 'theory of machinery' and the 'regulation and modification of force and motion,' he must be aware that he must have a fly wheel to equalise the inequalities which may occur during the running of the machine, lathe, or whatever he may be driving. Bearing this in mind, I proceeded to drive a fly wheel in the manner shown on the left of Fig. 2. The difference in gearing—3 in. at motor and 18 in. at wheel—at once showed signs of improvement, as the motor increased speed, and in a few moments ran the fly wheel at about 200 revolutions per minute. I next ran another gut to the lathe head (as shown to the right of Fig. 2), but the extra friction proved fatal to the speed, and eaused the fly wheel to run at 50 revolutions per minute. This shows that the intervention which Mr. Pitman speaks of, but which he does not recommend, is absolutely necessary. I have thoroughly tested the motor at other combinations of speeds, but find that which is illustrated the nearest to perfection. The quarter-man motor can drill a $\frac{1}{16}$ in. hole in brass, but very little pressure must be used, or it will stop.

"After exhaustive experiments with the New 'Demon' Water Motor, I find that it will run well if unopposed to any varying resistanee, but should the slightest irregularity in the resistance at the point driven continue, the motor will gradually stop and the impetus given by the fly wheel will be exhausted. Further, the time taken to regain speed is so long as to cause it to be entirely unfit for anything that it is recommended for in Mr. Pitman's circular. I have carefully examined the working parts, both inside and out, and find them well made, and capable of running for a long time without readjustment."

From this statement, the only inference to be drawn is that, although as far as workmanship and materials are concerned there is no reason whatever for taking exception to the machine, yet when it is set to work and subjeeted to a practical test, the power generated is so small that, beyond running any small machine with which it may be eonnected, it is not capable of overcoming the resistanee to the power that must naturally be expected, and will, as a matter of eourse, declare itself as soon as it is sought to carry out the kind of work, be it what it may, that is usually effected by the agency of the machine in question.

### 14.—Adams & Co.'s "Photographic Annual."

The "Photographic Annual for 1891," issued by Messrs. Adams & Co., 81, Aldersgate Street, E.C., is in reality the price list of these well-known wholesale and export dealers in photographic materials and appliances of every kind, for, of the 304 pages of whieh it consists, one-third, roundly speaking, is literary matter and two-thirds pricc list. The priee of the annual is 1s. 9d. post free, and the annual itself is well worth the money asked for it on aceount of the value and excellence of the papers that are to be found in it and the portraits which it contains, these being photographs of Mr. W. H. Harrison, editor of the *Photographic News*, printed on Schölzig's ready sensitised paper; Mr. J. Trail Taylor, editor of the *British Journal of Photography*, an Alpha print by the Britannia Works Company, Ilford, from a negative by H. Van Der Weyde; and Mr. Henry Sturmey, editor of *Photography*, printed on Fry's bromide paper, from a negative also by H. Van Der Weyde. Among the contributions are papers by Captain Abney, Mr. W. Jerome Harrison, Professor W. K. Burton, Mr. Chapman Jones, Mr. H. Snowden Warde, and other gentlemen well known in photographic circles.

### 15.—Messrs. Cox & Co.'s Price Lists.

Messrs. Cox & Co., Electricians and Electrical Engineers, have recently opened new premises at 11, Fetter Lane, Fleet Street, London, E.C., opposite the *Record* Office, for the sale of all scientific materials. The illustrated catalogue issued by these manufacturing electricians should be specially useful to amateurs. One useful feature in the eatalogue is that it is split up into different parts, distinguished as lists and sheets, each bearing a different letter with the exception of their "Temporary Priee List of Manufactures," which deals chiefly with electric bells, batteries, light fittings, and sounder telegraphs. Thus, List E forms an illustrated appendix to their electric list; Sheet M, the price list of thermometers, barometers, drawing instruments, and meteorological and other apparatus; and Sheet O deals with optical apparatus, race, field, and opera glasses. A visit to Messrs. Cox & Co.'s establishment cannot fail to be instructive and useful in a variety of ways.

### 16.—Messrs. Richard Garrett & Sons' Illustrated Catalogue.

Farmers on a large scale, who are readers of Work, may be glad to have their attention directed to the illustrated catalogue of steam engines, threshing and barn-work machinery, issued by Messrs. Richard Garrett & Sons, Leiston Works. As far as may be judged from the price list, and the engravings with which it is illustrated, the machinery supplied is certainly important in character, and seems to be of the best possible design and make. The most noticeable is their threshing and corn-dressing machine, Class O. F., fitted with the "Garrett-Ellis" patent drum beaters. Corn and manure drills, horse hoes, and other field implements are manufactured by the Company, whose works are of long standing, having been established in 1778.

I have received from Messrs. Henry Zilles and Co., 24 and 26, Wilson Street, Finsbury, the April part of *The Amateur*, eontaining some well-conceived figures for Pyrography or Poker Work. The figures, three in number, are equally well calculated for other decorative purposes and processes.

THE EDITOR.

## SHOP:

### A Corner for Those who Want to Talk It.

** In consequence of the great pressure upon the "Shop" columns of* Work, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* Work *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### II.—Questions Answered by Editor and Staff.

**American Lever Watch.**—Horol.—Grip the staff in a pair of pincers in one hand, and take hold of the balance with the other, and turn it round till the slot or notch in the staff is exactly behind the pin that works the lever; and see that when the pin is moving the lever, the ends of the fork are free in the notch of the staff when going in and out; and when the staff is round, that the pin is out of the fork. See that there is a little shake or freedom. Try both sides, and make the shake equal both sides. Regulate the depth of escape wheel on the pallets, till the escape teeth, when fallen on the pallet, only just catch on the safe corner of pallets. The best way to test the hair-spring for length is by trying it for time. If you have not broken any off, it should be long enough; but supposing any should be broken off and you find the clock gains, unpin the spring and lay it on an oilstone, take a cork, and gently grind it down, a little for width. Then re-pin it, and try again.—A. B. C.

**Nickel Solution.**—Curious.—The fault is not in the battery alone, although that is small, and I am surprised at the good results obtained from it. Your nickel solution has lost its free ammonia and become acid, hence the articles come out black. Get some blue litmus paper from a chemist and test the solution. If it turns the paper red, add some sulphate of ammonia, or liquor ammonia if you prefer it, to the solution until it ceases to redden the paper. If this does not cure it, add some more double salt of nickel (2 oz. to the gallon) to enrich the solution, stir up well, then pass the whole through a calico filter to remove the loose dirt. After this, test as before for free acid, and get it neutral before you attempt any more plating.—G. E. B.

**Bending Cased Tube.**—J. B. (*No Address*).—I am not quite clear as to whether you want to bend your $\frac{3}{4}$ in. cased tube to fit a curved bay window or an angular one. If the former, take a block of hard wood—say 3 in. square by 6 in. long—and bore a hole about 2 in. from one end. Let it be of such a size as to allow the pipe to slip easily through; fix the block of wood in a vice; place the tube in the hole, and gradually bend it, passing it through the hole as you do so; do not bend it too much the first time, and be careful to keep the tube always in the same plane—that is, after bending in one place. Do not lower or raise the tube when you make the next bend, or it will be "all of a twist," and very difficult to get right again. The way I usually fit up cased rods for a sharp angle bay is to mitre the ends, and to bend a piece of solid rod and fit it to the tube tightly and drive them on tightly: this makes the best job of it, as it is not practicable to bend cased rods or tubes sharply without damaging the brass casing. I might mention that the edges of the holes in the block of wood may with advantage be smoothed off a little.—R. A.

**Driving Lathe.**—Lathe.—If you cannot drive by the foot, there are many other ways you might adopt. A weight would do; but then, who would wind it up for you? also, it must be *very* heavy. Say you want 3,000 ft. lbs. per minute to drive your lathe, then you would require 1,000 lbs. falling one yard for every minute you work, or a weight of 60,000 lbs. falling one yard for every hour you work! I believe the Britannia Company, Colchester, make spring motors. You might have a little steam engine, like the hair-dressers do sometimes, or a gas engine, or a hot-air engine; or inquire what the water company would charge you per 1,000 gallons if you had a water motor; if not more than 6d. per 1,000, you could probably run a lathe by water for about 6d. per hour if the head is 60 ft.—F. A. M.

**Mounting Cushman Chuck.**—New Reader. I think from your question you must be trying to get your chuck true upon its face-plate by means of the screws; that will never do. Take it off, and observe the back of your Cushman; there you will notice a shallow recess, about $\frac{1}{16}$ in. deep, surrounding the central hole. You must turn away the outer part of the front of the flange, till you have produced a low cylindrical excreseence, not quite $\frac{1}{16}$ in. high, on to which your chuck will fit *without shake;* then fix your screws in any position, and the body of your chuck should run true. If you have already done this, and yet you find it does not hold work true, I would fit a small emery-wheel in a drilling spindle, and use that to grind the jaws of the chuck true; clamping a ring while truing the inside, and a bit of turned iron while truing the steps of jaws. You must not, however, expect absolute truth.—F. A. M.

**Carriage Varnishing.**—Barouche.—Carriage painting requires a seven years' apprenticeship. Without being so brief in reply as is the question, unfortunately, a concise account of the process shall be given, so that the tyro shall not go wrong and waste his time and money, and quite spoil his job at the attempt. An important omission in the question is not having said what sort of a carriage the learner desires to operate upon; another omission is not stating how much the carriage is worn that needs renovating, so that I am obliged to assume it to be a particular carriage, and that it needs to be varnished only, not retouched with paint and relief colours in part worn bare. Yet, I must not assume that, for no carriage that needs varnishing is perfect in its paint or colour beneath the varnish; again, if the colours had been mentioned, it would have enabled me to tell how to mix the repairing colours to match. These preliminary remarks should be noted by those who ask questions in Work, as, if the questions are fully stated, it makes the replies briefer and satisfactory. Why I ask what sort of a carriage it is, is because every description of carriage is constructed to take apart, and be put together for the special object of painting and varnishing a part properly. This is an important technical art in coachmaking, various carriages being taken to pieces in different manners. And this is what you must know, or your job will be a sorry botch. As the writer has assumed the *nom de plume* of "Barouche," perhaps it is a barouche he wishes to varnish; if so, it is one of the most difficult of open carriages to work upon. These carriages are built mostly on perch carriages, with Cee and under springs, costing new, from 180 to 220 guineas. I will assume the carriage to be a Stanhope phæton, as that general type of carriage will serve best to explain how many others are taken apart. Proceed thus: When thoroughly washed, put a trestle under the bottom of body, just behind the holting-on of the back-bed or "horn-bar" of top-carriage; this trestle must be about 3 in. higher than the bottom of body, so as to raise the body up, the springs will come open that much; do the same behind with a trestle under the bottom of body, just in front of the back crossbar, 3 in. higher than the normal height of bottom of boot. The fore carriage is termed top and bottom carriages, joined by a perch-bolt at the wheel-plate, where one turns on the other. They are parted by knocking back a bent linch-pin or key, which goes through a slit on the point of the perch-holt; you will need a steel drift-pin to effect this, as the key must be broken off close to the slit, mostly to get it out. Then the nut must be unscrewed right off; this needs a strong wrench, with jaws nearly 2 in. open, as this is mostly rusted and set fast, and you have to sit on the ground to work at it; take care it does not slip off the nut against your head, for you must pull towards your face, and it may cut an ugly gash that will delay the job a little while. I have seen it happen, even with experienced men. I may say that I admit writing feelingly on the subject, so I adopt a double-hammer tapping plan—that is, hold a 4 lb. hammer at an angle of the nut, and with a 6 oz. hammer tap the diagonal angle; this mostly starts the nut an eighth turn; then you may use the wrench to finish taking it off. Now, by lifting up the fore part of the vehicle body, the perch-holt comes out of the bottom bed only (it is almost a fixture in the top bed); pull away the under-carriage with front wheels, and let the body down again in its place on the trestle. The top carriage has now to be removed; this is done by unscrewing nuts from four bolts through the ends of the bed and horn-bar. You must have someone to help you here, not so much to get the beds down from the bolts, as to keep them from dropping from the bolts suddenly, and perhaps breaking the dub ends of beds in concussion with the ground; the foot sometimes saves the wood striking the ground: so much the worse for the foot. The hind part of carriage, *i.e.*, the back-bar, springs, hind axle, and wheels, are easily removed—four bolts go through the body bottom sides and bar; take off the nuts, and tap up the bolts quite out of their holes, then wheel back that part away from the body. You will find a lot of dry mud on the bottom of body, that the washing-off could not reach; get this quite clean. You may say, that part is out of sight; but varnishing is for a double purpose: preservation from decay as well as nice appearance; and, though the bottom is never varnished, it is japanned to preserve it, and made smooth for easy removal of mud in washing. Now remove the dash-iron by taking off the four nuts, and the side wings, and top-rail of body, mostly fixed with nuts. I must not pause long over little difficulties, as of a nut turning round yet not coming off; should this occur, hold the end of a bar of iron at one edge of the nut, and with a light hammer and sharp cold chisel cut the nut in halves. Should the bolt turn in the wood instead of the nut unscrewing, drive a piece of saw-blade under the bolt-head; the saw-blade to be cut out with a long notch the size of the square of the bolt. Get someone to hold against the pull of the wrench; if there is any difficulty, always cut the nut in halves, it saves time. Brush the lining thoroughly, and cover up with brown paper, American cloth, etc., tacked down to the rail at the edge of the seaming; lace the tacks only just to enter enough to hold. The hind seat is usually fixed with four or five screws, and they are mostly rusted in; consequently have a good taper blunt-edged screwdriver, tap it well into the notch of the screw, and jerk at the same time as you turn with all your might. I have heard coachmakers say you must not stand to a nicety about rupturing blood-vessels in trying to get out screws; sometimes the set-fast screws need to have their heads chipped away a bit at a time; then the seat lifts up clear of the screw, to be unscrewed by a hand-vice. When all these separate parts are away from the body, you will see that these detachments were necessary for varnishing, and moreover, useful to point out the state of preservation of the woodwork of body and carriage, and the reliability of the bolts, springs, axles, and ironwork generally. The wheels must be taken off the axles by unscrewing caps and nuts; these are put away in a marked box. The tyres may be worn, and need renewing or contracting to brace up the loose joints of felloes and spokes; if so, do not attempt these difficult jobs for a tyro, but write to a wheeler to send for the wheels; it will not be expensive, and is sure to be well done. I can name plenty of good men in town or country if needed; they will put everything right, even to painting correct colours ready for varnishing. The taking apart just described is called "unhanging" in the trade, from the old-time plan of unhanging a body swung on braces. Two men would do it in from three to four hours, or a coachmaker would show you how. Now, your varnishing must only be attempted when the old surface of varnish is prepared to receive the new. Every part must be flatted off with pumice-stone powder and water, and a piece of strong woollen cloth for rubbing. Begin at the upper parts, finish cleaning off, and work downwards, cleaning as you go with clean sponge; a very clean wash-leather is most essential. If the boot sides are sun-cracked in the old varnish, you must turn the body on the side, on old cushions, and pumice-stone down with lump pumice-stone, till you have worn down the cracked varnish to the body colour; it will then appear a dull slate colour. This, if black, is first japanned with japan, which is a semi-opaque black varnish. Should any small parts have been rubbed through to the lead-colour priming coats, these must be touched with black first, or, better still, give it all a coat of dead black, laid on quite thin, then flat-off lightly with pumice-stone powder, and when dry, japan it, using a good flat pointed brush and a small tool to get into the corners. Now for a wrinkle; you do not want to show the brush-marks on the varnished surface, as if combed after painting; this is avoided by holding the brush very slanting, about 35 degrees of angle to the face of the work; if held at 50 degrees the points of the bristles rake the japan or varnish, instead of *sleeking* it at the finish off of the stroke. The touching-up of relief-lines requires care, with sable or camel-hair pencils and colour to match. The rims of wheels, edges of springs, and shafts, are the most worn parts, and may need body colour as well as "picking out." Allow a day or two for colours to dry before varnishing. Do not attempt to varnish in a dusty or damp place; it must be a clean, dry place, even if warm; it will be better for the lustre of the varnish. The wheels are swung on a projecting spindle, so that you can get at the back and front faces of the wheel—beginning at the nave, and working down the spokes to the rim, which is done last, at the tyre edge, which, being dirty mostly, however clean it may appear, ensures the brush being kept clean till the last stroke. If you decide to give any part two coats of varnish, flat-off first to an egg-shell dulness. A clever painter will catch the drying of the first coat on the "tack," and with a delicate handling of brush give a second coat in a few hours after the first, instead of waiting two or three days and then flatting-off the first coat. When varnished, avoid walking about near it, as it raises dust, which makes the varnish specky. Avoid the job being near a manure heap, which will make the lustre of the varnish iridescent or rainbow-hued, ending in dulness. After the whole has stood for a few days and it feels fairly hard, wash off every part with clean cold water, with sponge and leather; you cannot wipe off too dry, the oxygen in the water is absorbed by the varnish, and makes it almost as hard as glass. This is the secret of the lustrous enamels now being sold: they contain a supply of oxygen. Now a question: Are you sure your carriage needs varnishing? You may say it looks so dull; that is no proof of want of varnish. The following fact, which I can vouch for, will explain:—Mr. Murchison, the celebrated geological explorer, sent his travelling carriage to his coachmaker to be varnished, but said it must be ready in three days to go abroad; he came punctually with post horses for his barouche, and was astonished to find his carriage more lustrous than he had ever seen it before, even when new, and asked the coach-maker what sort of varnish he had put on. "None at all," was the answer; "I have taken off some." "Explain!" said the great explorer. "Your carriage was overloaded with varnish, and it has been flatted-off with pumice and water, and polished with rotten-stone and oil, and the lustre worked up with the hand and old worn silk handkerchiefs. It will stand the hottest sun or keenest frost better than new varnish." This will impart to you how you may improve the panels of your carriage, for they receive little wear compared to wheels, springs, and carriage, should the panels appear dull and you defer varnishing. To put a carriage together that has been unhung, first, put up the top carriage, then the under carriage, well greasing the perch-bolt and wheel-plate. To do this, the wheels, front and hack, may be put on the axles temporarily to uphold the springs; remove the trestles, and clean and oil the axles one at a time, bolt on dasher wings and body-rail, then touch up the nuts with colour or japan afterwards. As to where to get materials,

the largest and best selected stock of carriage materials, rough and finished, is to be got of Messrs. Whittingham and Wilkins, 136, Long Acre, W.C. They will advise in the selection of prepared colours, varnishes (always copal), and brushes and pencils. —J. C. K.

**Duplicating on Photo Plate.** — AMATEUR. — If small grooved strips of wood are attached to the upper and lower part of the framing of the camera, immediately in front of the position the sensitive plate will occupy, and a piece of blackened zinc sufficiently wide to cover *half* the plate, and sliding in this groove from side to side as occasion may require, all that is necessary will be provided for taking *two* pictures on *one* plate. The screen being fitted, one exposure is made; close the shutter of the slide, and alter the position of the zinc screen, and make the other exposure. This is a very simple, workable, and effective contrivance.—E. D.

**Wiping Joints.**—A NEW READER.—It *is* usual to "tin" the parts to be joined, but the tinning is done by wiping the molten metal round the joint, which, of course, is previously cleaned and greased with tallow or a mixture of resin and tallow. You say you melt down the "ordinary" solder in bars. What do you call ordinary solder? Perhaps you have been using tinman's solder. If so, this is too fine—that is, it will "run" too freely, and could not be wiped up into the right shape. Your solder for wiping joints should be a mixture of lead, two parts; tin, one part—pounds, ounces, or anything you please in the above proportions.—R. A.

**Oval Boiler Lid.**—J. S. (*Poplar*).—To make this, first ascertain the inside circumference of the boiler. A rough estimate can be formed by taking twice the length and once the width of the article. Having found this, divide it into three or more parts, according to the length of the stuff you have to cut the rim out of. Thus, if the boiler requires a rim 39 or 40 in. round, three lengths off a "single" plate which is 14 in. long would do very well. Cut them 1⅜ or 1½ in. in depth. The pieces should be not quite straight, but slightly curved; tack them together so as to preserve the evenness of the curve, and fold over ½ on the inner side of the curve (this is done on the hatchet stake); flatten it down, and turn round; shape to the boiler and tack it so that it fits well, but not too tightly. Next throw off an edge—this also on the hatchet, unless you possess a "jenny." This will put the rim out of shape, so it must be put right again before proceeding with the next process, which is cutting out the top. Place the shaped rim on a plate of tin of sufficient size and mark round the outside of the edge of the rim: cut ⅜ of an inch larger all round—this will allow for hollowing; for this a wooden block will be required, and one or two block hammers, and this is the process that will give most trouble. Make a ring of blows about 3 in. from the edge all round, and then work towards the outside, smoothing out the puckers as you go along. Use light blows, then go over it again with slightly heavier blows, and you will find it working up. When hollowed up sufficiently, smooth it off. Place it on a flat place, and see if it touches all round; if not, press it into such shape that it will do so. Throw off a wide flange on a crease iron or bick iron, if no jenny is available; then turn up an edge, and slip rim in, and pane down the edge. The making and fixing of cover handle I think you will not need to have explained.—R. A.

**Mosaic Flooring.**—MOSAIC.—Form the foundation of hard dry material well rammed, and bring it up within 6 in. of the finished surface. Cover this with 3 in. thick of broken stones, well rammed down, and lay upon the stones 2 in. of cement concrete, formed of six parts of crushed bricks and one part of cement. This must be finished level, and allowed to set hard. Then lay out the centre portion of the floor between the borders by means of laths 3 in. by 1 in., planed straight, and laid to the exact size of the centre portion. The tesseræ can be had cemented together in slabs about 8 in. square; but when made in this way they are above 1 in. thick, and the surface of the cement concrete must be ½ in. below the slabs to allow for cement jointing. They can also be had fixed on strong paper, the face being next the paper, and in this case are not so thick as when formed into slabs; but they are much more difficult to lay, on account of not being able to see the face of the work. Great care is also needed in jointing one to the other, and there is a danger of the outside pieces coming off the paper when they have to be fixed by hand. In whichever way you get them, they are laid in the same manner as encaustic tiles on a bed of cement, and beat down level with the laths by means of a hammer and a piece of flat board. If you refer to page 428, No. 79, Vol. II. of WORK, you will find a description and sketches of the method of tile laying, which may be of service to you. You will receive from the firm supplying the tesseræ a plan showing the various parts of the floor in colours, which, if they are formed into slabs, you will easily understand, and if they are fixed on paper, will be marked or numbered for your guidance. You must be very careful in handling them, if on paper, to see that none of the pieces drop out; should any do so, you will have to insert them after you have beaten them down. The paper will come off while you are beating them down. You will also, most likely, receive printed instructions for laying them when the plan is sent. As you have not laid any before, I should advise you to get someone to assist you in laying them who has had experience, as they are much more difficult to lay than ordinary tiles.—M.

**Polishing Paste.**—PASTE.—(1) *Sweet* or *olive* oil will be best for moistening the paste. (2) Emery is the active ingredient in most preparations for polishing metals, though putty-powder (calcined oxide of tin) is also a valuable material for that purpose. But PASTE asks how a *cheap* paste for polishing knives may be made. The following has been recommended as inexpensive, and at the same time efficacious, and not liable to wear away or blunt the knives:—Brickdust and scraped yellow soap are to be pounded and mixed together. The paste is moistened with water, and applied on flannel. The blades require to be washed with warm water after using the paste.—S. W.

**Choice of Trade.**—TERRA COTTA.—Without knowing what your capabilities are, it is difficult to advise you, but assuming that you have to work for a living, I should advise you to remain at your present occupation, and learn all the different branches of the trade. You should also make yourself acquainted with the various clays and brick-earths, methods of mixing, moulding, and burning, as these vary in different districts. As to wages, if you get to be expert in all branches you might get £2 per week or more, or you might get to be a foreman or manager in a large works, at a higher rate. If you have any talent for modelling, and follow it up, you can obtain better pay. Terra-cotta and encaustic tile work are also higher branches, if you can get into them. To become a draughtsman, you should go as an apprentice or articled pupil into a drawing office. After serving your time, you might get 25s. or 30s. per week to begin with, gradually advancing according to your abilities; but you will require influence or have to pay a premium to get into an office, and would probably receive no salary till out of your time. You can learn drawing while at your present employment by joining a science class, which would not cost more than 5s. per term. You should learn freehand, model, perspective, machine and building construction, plane and solid geometry, and mathematics. If you get to be expert at these, you might then get a situation as a draughtsman.—M.

**Silvering Buttons.**—E. W. (*Leith*).—There is no method I know of to "silver" brass buttons to stand exposure for an unlimited length of time to all weathers except the Sheffield method of plating, or the way in which harness is plated—that is, by covering them over entirely with sheet-silver. Even these would be bound to wear through with continual cleaning; and besides, silver could hardly be applied in the form of sheets to any finished buttons except plain ones. Are you not asking for an impossibility? Look at the silver in your pocket, and you will see how sixpences and other coins get worn down. Now, should not this bit of common experience have caused you to question the possibility of depositing silver in anything like the same thickness you here see worn off? Cannot you procure the buttons in German silver instead of brass? then you would always be able to restore the colour by brushing where the plating had worn off.—H. S. G.

**Light Dog-Cart.**—N. I. (*Falsgrave*).—The measurements of a dog-cart suitable for a pony thirteen hands are as follows:—The framework of the body to be of oak and panelled with baywood or birch. The length of body on top rail is 36 in., the length of the body at the bottom from the back to the front in a straight line is 57 in., the depth of the side is 20 in. The width of the body at the top is 36 in., at the bottom 34 in. The front dash and the splash wings can be of birch or white-wood or enamelled leather; the splash wings if of wood will be 36 in. long, 6 in. wide, and ¼ in. thick. The shafts are of lance-wood, and fit at the outside of the body. The length of the shaft from the tip to the draw-bar is 63½ in.; the rest of the shaft extends to the end of the body. The seats are 36 in. long by 13 in. wide, the front seat having a back-rest upholstered both sides. The springs are 46 in. from centre to centre of eyes, with five laps or plates in each spring, 1½ in. wide, and ¼ in. thick each lap. Either the Collinge or mail axles can be used. The wheels will be 4 ft high when finished. The nave 8 in. long by 6 in. wide. Spokes, width 1½ in. by 1¼ in. thickness. Felloes, thickness 1⅜ in. The width of the tire 1⅜ in. by ½ in. thick. The lamps, as is now fashionable, should be placed at each side of the body near the wheel. The body should be painted black without any finishing or striping, with just simply a monogram in gold or colour in the centre panel at the back and the two sides, or a crest if entitled to one; the wheels, springs, and shafts to be painted vermilion picked out with a quarter-line of black. I do not understand your first query. Is it a lorry for a pony you mean? If you could send a rough sketch of what you want it would greatly oblige.—W. P.

**Clock Parts, Etc.**—H. R. P. (*Lambeth*).—Pack your clock, and take it to Grimshaw & Co., 35, Goswell Road, Clerkenwell, and tell them to make your face and fit hands; give them instructions as to shape, size, style, etc. They would also get a case made for you as you want; or for case you might try J. J. Stockall, 6 and 8, Clerkenwell Road: he may be able to get a case made for you. —A. B. C.

**Sizes of Bassinette.**—H. W. (*Manchester*).—Your query for sizes of wooden bassinette, coach style, to seat two children, is one to which I am unable to reply. I am frequently drawing bassinettes (on paper) for manufacturers, but as I do not draw them to scale, I never trouble to measure them. There is no reason why you should not discard stock dimensions, and use your own judgment as to those most suitable for your purpose.—J. S.

**Polishing.**—J. W. (*Birkenhead*).—Undoubtedly, polishing is better for such a piece of work as your small cabinet than varnishing. This has been repeatedly stated in "Shop." If you have already stuck down the frets on the panels, you will only make a mess of the job if you try to stain, varnish, or polish the sunk ground, either with glaze or anything else. It will be necessary to leave this part of the work in the white. If you wish to do so, you may oil it, but it is questionable whether you will improve the appearance by doing so. The plain portions can be polished after staining black or any other colour. Stain first, then size, and finally polish in the usual way, using black polish if the job has been stained black. Dull down, if required, with emery powder. Black polish can be made by adding a little gas black to ordinary polish. If you want your little cabinet well finished, it may interest you to know that Mr. F. Warrington, 47, 49, and 51, Heath Street, Myrtle Street, Liverpool, makes a speciality of finishing work for amateurs. He is a polisher of wide experience, and his charge for doing the cabinet will only be trifling.—D. D.

**Upholstery.**—T. G. (*Neston*).—The job you propose is a very ambitious one for a novice. You would require to know vastly more than the mere construction of the roll and its stitches before you could have the slightest chance of success. You could hardly have selected a more difficult job in ordinary upholstery. The small chairs you might possibly manage to do—after a fashion—but not the couch and easies.—D. D.

**Chess Board and Scraps.**—R. W. M. (*Kildare*) —To make a chess board, get a sound dry piece of mahogany. Clamp the ends so as to form a square of the desired size, and you may consider the base ready. Get some veneers of the colours you intend to form the squares of. Cut them into the requisite number of square pieces. Glue them down in proper order on a piece of paper. Outside them lay a piece of stringing, either plain or mosaic, and beyond them borders of a suitable width of mahogany. Lay on one side till dry, then go over the unpapered side of the veneers and the top of the base with a toothed plane. Glue and lay down the veneer. When the glue has set, clean off the paper, smooth down, work mouldings (if any) on the edges of the board, and finally finish off by French polishing. For the complete process of laying veneers, read the exhaustive series of articles on the subject in Vol. I. of WORK. I am afraid that you will have some difficulty in removing your scraps from the screen, as they have been varnished, without injuring them. A good deal, however, will depend on the material to which they have been stuck. If it is calico or any similar substance which will allow moisture to act on the backs of the pictures, the removal will be easier than if it is finished with a waterproofed facing. With a porous backing, all you have to do is to apply warm water till the glue is sufficiently soft to allow of the pictures being removed. In the other case, give it up as a bad job.—D. A.

**Polishing.**—G. W. (*Plumstead*).—To finish a wide surface with glaze, free from dull streaks and from ridges, the glaze should be used as a polish; see that the surface is free from oil, the rubber soft and free from lint. Apply the glaze as evenly as possible, going over the surface several times, until the rubber is nearly dry; then with the smallest quantity of oil and a little spirits go over the glaze, very lightly at first, varying the direction of the rubber to avoid ridges. A *dull*, even surface may be obtained by adding one-third to one-half of sandarach to the solution of benzoin, and using the rubber damp only—not saturated.—F. P.

**Milling Machine.** — DESPAIR. — The milling machine bears about the same relationship to the file that the circular saw mill bears to the hand saw. There are, of course, some kinds of work to which files must be applied and milling cutters cannot be used instead. Milling cutters may be worked at such a high rate of speed, and the feed of the work into cut can be so rapid, that any work a milling machine can tackle may be done on this machine quicker than on any other. As to the quality of the work, its evenness, straightness, and smoothness are the nearest approach to perfection of that of any machine tool, and if keen-edged cutters are employed, there is no way of improving this, short of grinding and polishing. Milling by circular cutters is not treated upon exclusively in any book, but a dozen pages are given on this subject in "The Metal Turner's Handy Book," price 2s., published by Lockwood & Son, and the information there given would enable you to form an idea of the capacity of this method of shaping metals. For the purposes you name, a valve milling machine would be the kind best suited, having two or four spindles and using end or butt cutters. There is no better machine than this to do such work; it is specially designed for milling the square and hexagon parts of brass cocks and similar fittings. The spindles are adjusted independently by hand wheels, so that the cutters can be brought together or separated to any distance within the limits of the machine. After adjusting the cutters and milling two opposite sides, the work is rotated through an angle of 90° for a square, 60° for a hexagon, or 45° for an octagon, and again traversed between the spindles, by which process two other opposite flats are milled true and to precisely the same gauge. This second process would complete a square, but a third traverse is

necessary for a hexagon, and a fourth for an octagon.—D. H.

**Gilding on Glass.**—YOUNG SIGN WRITER.—The process is too long to describe in this column; it requires one or two articles to treat upon it practically, and give full working details. Perhaps the Editor will soon see his way elear to give these chapters. I am not at all surprised that you should know nothing whatever on this subject, as there are many good writers who never attempt it, and look upon it as the work of a speeialist, such as the glass embosser. It is not very difficult, however, and, had I the space, I could give such clear direetions that any sign writer eould execute the work with ease and eredit. You ask about the size used for fixing the leaf to the glass: you are mistaken in surmising that this is the ordinary gold size, for it is not, and no decent work could be done with it. The size is made by the writer as follows:—Purchase some fine isinglass, or Nelson's No. 1 gelatine, and take as mueh of this as ean be placed on a shilling without piling it too high; place this in a tea cup half full of boiling water, and stir well till thoroughly dissolved. Before the size has had time to eool, fill up the cup with pure spirits of wine, and incorporate well together. The size is then strained through a piece of fine linen, or, better still, silk handkerchief, and is then ready for use. The gold leaf used is the ordinary kind. The lettering is first set out on paper, being of eourse reversed: this is pasted on the outside of the glass. The glass is thoroughly cleaned inside and polished with tale. The letters are then formed with the size, using a good camel-hair pencil, and the gold leaf is lifted from the cushion with a "tip" and dabbed with eotton wool. When dry, the gold assumes a burnished appearanee; and if now it is rubbed with a pieee of eotton wool, the brillianey will be increased. The gilding is now repeated, the same process being followed; and, when dry, the loose gold round the edges is removed with cotton wool.—H. L. B.

**Air Gun Walking Stick.**—G. E. B. and W. LONGDEN.—There is a lock to the gun in the fore half of the barrel, between the trigger and the middle serew joint. The air-ehamber is in the rear half of the walking stick, of thin iron; the barrel, half serewed in front of it, though only bored for a ¼ in. bullet and charge, is necessarily of stout iron to continue the outward semblanee of a walking stiek. It is in this thickness of iron between the bore and the outside that a slotted recess is eut in whieh the trigger-spring works—out of sight, as it is cased in by a thin covering of iron flush with the rest of the stick; an outer skin, as it were, just at this part only. This spring aets upon a plunger just at the baek of the charge ehamber. When the trigger is pressed, this plunger—about ¼ in. diameter or less—strikes a piston in the centre of barrel air-chamber just past the joint of the two barrels. This lets out a jet of air, which passes the plunger and drives out the eharge from fore barrel. The valves are packed with soft leather, and the piston is kept up to its plaee by a eoil-spring till driven back by the plunger striking it in the eentre. The look in its reeess is somewhat like the ordinary lock and spring of a gun, but small. The air does not get to the lock, as it is outside the ehamber or charge bore. The outlet for the charges of air that escape is the same, but pressure is less forcible towards the last charge of five or six charges or air impulsions.—J. C. K.

**Indiarubber Felloes.**—J. H. (*Winchcombe*). Mr. Aves, Barbiean, E.C., rubber felloe manufacturer, is the inventor, to whom apply.—J. C. K.

**Enamel Cloth.**—E. L. (*Woolwich*).—For enamel cloth used for infantry men's valises, try Whittingham & Wilkins, 135, Long Aere, W.C.—J. C. K.

**Prize Bookcase.**—W. H. B. (*Birmingham*).—If you will kindly let me know what you eannot understand, I shall be pleased to put you right.—E. D.

**Sign Writing—Spaeing Letters.**—IMPROVER.—The whole of the information you require is to be found in the articles on "Sign Writing and Lettering," which appeared in Vol. I. of WORK, part in one chapter and partly in others. Get Part 4 or No. 17, and you will find pretty elear instruetions therein for giving a symmetrieal appearanee to words. It must be remembered that all letters should not be the same distanee apart; for instanee, the space between such letters as K, O, P, Q, V, W, and Y, and the letters on either side of them should be less than for ordinary letters; and the same rule applies to "serif" letters; they must be kept eloser together (see example, page 259, Vol. I., in above number of WORK). I have also given directions for spacing large letters on high walls in one of the chapters, but am unable to trace the exact chapter just now. Briefly, no fixed rule can be followed, as no two situations would be alike, and the letters must, of course, be formed as to size and spacing to suit the circumstances of the case. An experienced writer finds no trouble in doing this, but a novice will find it easier to first measure his space on the wall and then arrange his matter on a blank wall near the ground. When the size and spacing of his letters are satisfactory, he can take full measurements, jot them down in his pocket book, and then, by the aid of these and a measuring rod or straight-edge, proeeed to set out his work on the gable end of the house or any other high situation. All this is really not diffieult, and you should watch a good sign writer at work. There is not mueh scope in your town, I know, for very high-class work—the narrow streets will not allow it—but you, no doubt are frequently in Birmingham, and here you can often see writers engaged, sky high, on gigantic letters. In London, "sky signs" are injuring this class of work.—H. L. B.

**Volume of WORK.**—OLD NORWICH.—15 per eent. duty will be ehargeable upon volumes which you may send to Canada.

**Cost of Dynamo.**—ELECTRIC.—You have neglected to give the voltage of the dynamo, hence I eannot give you a definite reply. A dynamo to give 10 ampères of current may have a voltage of 10, 20, 50, 100, 500, or more volts, and its eost rises with the voltage from £10 to £100, or more. The horse-power will also rise with the voltage from ⅛ h.p. for a dynamo to give a eurrent of 10 ampères at 10 volts pressure, up to 7 h.p. for a maehine giving 10 ampères at 500 volts pressure.—G. E. B.

**Shocking Machine.**—F. V. (*London*).—Have two sliding bars for handles. The left-hand handle should be fitted with a lever moving a switch to throw the battery in or out of action. A noteh is made in the upper part of the bar, and in this notch fits the short end of a lever to prevent the bar from being pulled out until a penny, falling into a small seoop at the longer end of the lever, tilts it up free from the notch. The other sliding bar is to be connected to the sliding regulator of the eoil, and must also have a transverse pieee of brass fitted to it to sweep the penny into the till as the bar is drawn out. Attach a cord or pieee of eatgut to the sliding regulator and pass this cord over a pulley on the spindle of the dial hand. Cords attached to weights should draw the handles back when they are released. By pulling out the left-hand handle the battery is thrown into action. By drawing out the right-hand handle the strength of the shock is regulated, and this is shown on the dial. When the handles are released, they are drawn into the box, and the locking lever falls into its place again and locks the switeh.—G. E. B.

**Staining.**—CLYDESIDE.—You will find in No. 95, Vol. II., a paper on "Imitation of Woods by Plain Staining," etc. A direct referenee is made to maple staining, and I can only add that yellow pine, if simply varnished with eopal, two or three eoats, or twice sized and once varnished, if expense is an object, will be as near the tone of maple as you will get it without painting and graining. Now go earefully through the paper, and then ask yourself—Is it fair to want more from us? If you desire to ornament the eot, put some of the same ingenuity and perseverance at work in reference to papers on "Imitation Inlaying" that you have already displayed in making the eot itself.—DECORATOR.

**Pitch Pine.**—SAW MILL.—You question the correctness of sentence eommeneing "Real pitch pine," to "from the Baltic," in page 694, Vol. II. I have to answer that (1) the articles being treated from a grainer's point of view, "Real piteh pine" was a term used to express, in a general sense, those figured varieties of pine wood belonging to the natural order *Coniferæ*, commonly known to the grainer as "pitch pine." The illustration accompanying the paper was used for explaining technical processes, and shows a simple grain of the wood alluded to. (2) I am aware that much pine wood comes from the States, as instanee the celebrated pitch pine of Savannah; but it does not eome from the States *only*, as your note implies, for in 1876, I find, nearly 300,000 tons of white pine and 40,000 tons of red pine were exported from the *Dominion of Canada*. (3) Beyond this, the genus *Pinus* is not only indigenous to the countries of the Baltie, but even to Northern Britain; and, finally, I beg to state that the writer has a very intimate eonnection with a seaport, very remote from Liverpool, to whieh piteh pine is imported from the Baltie, and where it is largely used as stated in the artiele.—DECORATOR.

**Paint Queries.**—W.S. (*Inverness-shire*).—For full particulars of plain painting and the nature and uses of all painters' pigments and fluids, see series of papers thereon in WORK, Vol. I. Get it at once before the price goes up to a guinea, whieh is its true value to most people! For external—*i.e.*, preservative—painting little or no turpentine is neeessary. The provinee of the latter oil is to thin the linseed or get "dead" surfaces of work. Quantity of driers depends partly on the pigment used, some having a natural drying power, and others quite the opposite. For most pigments and lead paints, one of driers to ten of pigment in winter, and one to sixteen in summer, would suffiee. This, again, is qualified by (1) the strength and quality of the driers, and (2) the purity of the oil. Boiled linseed oil is usually substituted for the ordinary raw oil for external painting, and partieularly for ironwork. Being boiled upon *oxides of lead*, etc., it takes up their drying nature, and is therefrom often termed "drying oil." The process makes it thieker and darker, and hence it is only suitable for dark-coloured paints. The drying power makes it also more susceptible to blistering on most kinds of woodwork, and many painters don't use it at all nowadays. Red lead, being *oxide of lead*, is a natural drier, and this, added to its natural weight, causes it to settle and harden when lying by. Remedy—Mix only as mueh as you want for use each day, and so keep it well stirred. You will gather that the oxide of lead communicates its powers of oxidisation to the oil it is mixed in, and thus not only dries it when in ordinary use, but continues such action upon it when standing, and makes the paint "fat," in professional parlance.—F. P.

**Emigration and Employment.**—ABSTAINER.—It seems from your letter that you are an able-bodied man, ready and willing to turn your hand to anything, and that you have saved a little money. Further, to judge from the locality in which you live at present, you are accustomed to agricultural work, and can do a little in chair-making. The best thing you can do is to write to John Pulker, Esq., Emigrants' Information Office, 31, Broadway, London, S.W. State your age, say you wish to emigrate to South Africa, and ask him to send you sueh papers as may tell you what to do in order to obtain assistanee in getting there. He will send you the neeessary forms of application, etc. You might eertainly be able to work your passage out, but I am not acquainted with any shippers, so with regard to this I can give you no particular information as to the best means of getting a ship. As, however, you are not a sailor, you would be unaccustomed to the work on board ship, and, I daresay, would find difficulty in getting on any ship's books. You would find it better in every way to go out as an emigrant assisted by Government.

**How to Make a Telephone.**—H. P. (*Oxford*).—An artiele on the above subjeet appeared in No. 23 of WORK.

**Machine Rollers.**—BREMNER.—I fear the advice you ask for in your letter will not be of mueh service, as I can scarcely understand what your difficulty is. The "hopping" of rollers over the type suggests to me that the runners of your maehine are too low, or perhaps worn rough; then the "lifts" would not support the rollers at all, and their full weight would press on the "forme." Try nailing on strips of thiek wrapper or cardboard with tinned taeks, the length of the runners from the slab to the "piteh." If one thiekness is not suffieient, add others till the rollers "fliek" over the "forme" merely. After washing your rollers after the job is off with petroleum, or turpentine, or terebine, do you sponge them over just before using them again with a sponge and elean eold water? This restores the "bite." The sponge should be merely well damped, not wet. If you find the "suetion" is not renewed by this means, your rollers want re-eovering with new composition, which should not be used too "green"—*i.e.*, too new. Be eareful to see that your roller "lifts" are exactly of the diameter of the roller-mould, or they will be sure to jump on the "forme." I strongly recommend the "Durable" roller composition as being more economical and lasting longer, and also having more bite or suetion on the ink-slab and formes. If you have a "blank" page, or a title, or other light page, or part of a page in the forme, nail on the runner nearest to it, exaetly opposite it, an extra strip, or even two, to lift the ends of the rollers higher still over that part. A little experimenting in this direction will give you a new sense of power over your ink supply, and enable you to avoid a light page being over-inked, and a heavy page thereby being robbed of its full inking. Write again if I have misunderstood your queries, and send to the Durable Printers' Roller Co., Limited, 57, Shoe Lane, for price list and information.—J. W. H.

**Bookshelf Leather.**—C. A. F. (*Holland Park*).—This is obtainable of Messrs. E. J. Willson & Son, 21, St. Bride Street, London, E.C.

**Cast Brass Cooking Utensils.**—If anyone ean supply you with the articles mentioned in your query, it would be Messrs. Benham & Froude, Chandos Street, London, W.C.—R. A.

**Spark from Induction Coil.**—R. E. L. (*Chingford*).—From a coil having a core 9 in. in length by ¾ in. in diameter, wound with 4 lbs. of No. 35 silk-covered copper wire as a seeondary eoil, and having a eondenser of 150 sheets, you should get at least a 2 in. spark, if the eoil has been properly eonstructed. I see, however, that you have started with an initial fault in employing No. 16 double cotton-eovered wire as the primary. The insulation should be silk-covered, soaked in melted paraffin. Shellac varnish is not the best insulator. You fail to get more than a ¾ in. spark because the coil is badly insulated, and therefore you increase the trouble by employing more eells, since the higher tension eurrent then pierces the defective insulation, and the extra eurrent is absorbed in the coil instead of traversing the secondary, and appearing at the points in the form of sparks. If you go on increasing the cells, you will entirely ruin the insulation of the wires, and also the condenser, by internal sparking. The effieieney of the condenser is shown by deereased spark at the break, and increased spark at the terminal points.—G. E. B.

**Induction Coil.**—R. MCC. (*Glasgow*).—A 7 in. core should not be 1 in. in diameter. Half of this is quite enough for sueh a small eoil. The paper tube should be only $\frac{1}{16}$ instead of ¼ in. in thickness, and should fit close to the core. The primary should be No. 18 or 20 silk-eovered, not No. 16 double eotton-eovered wire. You eannot get this large size close enough to the eore to properly magnetise the iron. If the eoil is for sparks, you will find better results from No. 36 than from No. 34 as a seeondary. Soak all the wire in melted paraffin wax before winding it on the coil. See that the hammer of the break is not too heavy or the spring too strong to allow free working of the break.—G. E. B.

**Electric Bell.**—A. G. F. (*High Wycombe*).—If you get No. 18 of WORK—and you can get the number direet from the office for 1½d.—you will find therein a full illustrated description of the "parts of an eleetric bell whieh cause the bell to ring," and "proper" instruetions showing the way to make them. In a series of articles on "Burglar Alarums," running through the first volume of WORK, the making and fixing of electric bells are described.

The articles appeared in Nos. 12, 18, 20, 27, 31, and 33 of WORK.—G. E. B.

**Whitening Silver-Soldered Joints.**—C. C. (*Birmingham*).—I suppose you have hard-soldered the joints, and in doing this have brought the copper of the silver alloy to the surface. This causes the smoky brown stain of which you complain. You have failed in boiling out the stain in dilute vitriol, because you are using the pickle too strong, and do not warm your work enough before putting it in the pickle. Use one part oil of vitriol to forty parts of water, and heat the work to a dull red after soldering. If the joint is soft-soldered, or the silver is poor, you must electro-plate the article to whiten it after soldering.—G. E. B.

**Fan Mounting.**—A. H. W. (*London, W.*).—Mdme. Ida, 7, Prince's Street, Regent Street, London, W. (entrance in Castle Street), intends taking up fan mounting. She has only lately commenced business on her own account, so the fan mounting may not be started yet. A. H. W. could inquire there. Also of Mrs. Haitland, Amberly Art Studio, Crouch Hill, N.—C.

**Small Tin Boxes.**—PASTE.—You can obtain small tin boxes such as you inquire for, suitable for paste, blacking, etc., from either of the following:—A. Truelove, 14, Carver Street, Sheffield; or G. Stradling, 21, Florida Street, Bethnal Green, London, E.C. They are very cheap, and the makers will quote you a price according to the quantity that you require.—R. A.

**Claws or Feet for Fountain.**—J. R. P. (*Uttoxeter*).—You will get these through any local furnishing ironmonger; if not, try and make some yourself—first modelling them in clay; then take a cast in plaster of Paris, and from this make castings of melted compo. pipe. As they are for ornament only, they can afterwards be soft-soldered to the legs of the stand, as shown in the design.—C. M. W.

**Electro-Motive Force of Batteries.**—R. E. L. (*Chingford*).—The E.M.F. of zinc and carbon immersed in the ordinary bichromate of potash solution employed in charging battery cells is about 2 volts at the instant of closing the circuit. All sizes of plates have the same E.M.F. The internal resistance of a single cell having plates 7 in. by 4 in., and placed ½ in. apart, would be about ·03 ohm. Therefore, the current at the terminals of a battery of three such cells would be at the moment of closing the circuit $\frac{3 \times 2}{3 \times \cdot 03} = \frac{6}{\cdot 09} = 66{\cdot}6$ ampères. Through a resistance of 1 ohm, the current would be 5·5 ampères only at the moment of closing the circuit. The E.M.F. falls, the internal resistance rises, and the current falls as soon as current begins to pass. As the E.M.F. of the three elements under favourable conditions in a solution of 1 sulphuric acid to 12 of water is only ·57 volt, we must employ plates of sufficient size, and put them near enough together to pull down the internal resistance to ·5 ohm, if we wish to get a current of 1 ampere from the battery.—G. E. B.

**Drain Work.**—W. B. & Co. (*Hammersmith*).—You will probably find a suitable book in the following list:—"Handbook on House Sanitation," by E. F. Bailey Denton, price 4s.; "Sanitary Engineering," by J. Bailey Denton, price 25s.; "Sanitary Engineering," by Baldwin Latham, 21s., published by B. T. Batsford, 52, High Holborn; "The Sanitary Drainage of Houses and Towns," G. E. Waring, price 10s. 6d.; "House Sanitation," by G. W. Stanger, price 1s.; "House Drainage and Sanitary Plumbing," by W. Paul Gerhard, price 2s.; "How to Drain a House," by G. E. Waring, price 6s., published by Spon, 125, Strand. As you live in London, you could see them, and decide which is most suitable for your requirements before purchasing.—M.

**Electric Incandescent Lamps.**—J. M. (*Halifax*).—Electric incandescent lamps of 10 candle-power, or of any candle-power, have no chimney of any kind, nor any wick, flat, round, or otherwise, as in paraffin lamps. They are simply little globes of glass, made quite air-tight, with a thread or wire of carbon sealed in each globe. When the electric current goes through this wire it gets white hot, like iron at a welding heat, and this gives out the light. The wire does not burn away. You must have a battery or a machine, as well as a lamp. Read my articles on "Model Electric Lights" in Vol. II. of WORK.—G. E. B.

**Accumulator.**—E. G. (*Erdington*).—I do not know a 6 c.p. lamp. The Edison-Swan lamps are made of 5 and 8 c.p., but nothing between. The 8-volt 5 c.p. lamps take about 3 ampères of current, and the 16-volt 8 c.p. lamps take about 2·7 ampères of current to light them. They would thus need an accumulator having a capacity of from fifteen to eighteen ampère hours to light the lamps up from five to six hours. You would find a four-celled V type E.P.S. accumulator enough for the 5 c.p. lamp, and an eight-celled V type E.P.S. accumulator suitable to the 8 c.p. lamp. There are three plates in each cell, and four or eight cells respectively in each box. The external dimensions of the boxes are given at 6 and 7 in the table on page 791, Vol. II. of WORK, but the number of plates differ. Instructions are also given there for making and charging accumulators.—G. E. B.

**Measuring Glass.**—J. J. F. (*Shaftesbury*).—The following apparatus are required to estimate the hardness of water by Dr. Clark's method:—Mohr's burette with pinchcock, 25 c.c., in 250 divisions, 2s. 6d.; stand for ditto, 1s. 9d.; 70 c.c. pipette, to measure out the water, 11d.; 1,000 c.c. flask, with mark on neck, 1s. 6d.; and a stoppered bottle to hold 7 or 8 ozs., 4d. For alcohol, get ½ pint methylated spirits (3d.), and dilute it by putting 350 c.c. (measured out by taking 70 c.c. five times) into the 1,000 c.c. flask, filling the flask up to the mark with distilled water, and shaking well. If your chemist has not these things, he will get them for you, and you might ask him to show you how to use them. There is no need to convert the quantities given into English measures, as the apparatus are sold as above. 1,000 c.c. flasks often have "1 litre" ground on them; 1 litre is 1,000 c.c. Get "Wanklyn's Water Analysis," published by Trübner & Co., Ludgate Hill, for 5s.: it is written so plainly that you will understand it.—F. B. C.

**Ship Model.**—R. 'J. (*Rawtenstall*).—You had better get someone in the neighbourhood to furnish you with the design you require of a ship stationed, as you say, at Leith.

**Fire Smoking.**—H.S. (*Milnsbridge*).—If you refer back to the answer to F. W. B., on page 46, No. 55, Vol. II., you will there see some of the difficulties in dealing with smoky chimneys pointed out. In that instance there was some doubt as to why the smoking occurred, but in your case it is pretty plain. For example, in the first place, it leaves off smoking when you open the sash, which clearly shows that the fire is not sufficiently supplied with fresh air: the remedy for this you will find explained in the answer spoken of above. If this was the only defect, the matter would be simple enough; but when you say it also smokes when the fire in this particular room is *not* alight, and other fires (or fire) are, the matter at once becomes complicated. This may arise from a variety of causes, a few of which are:—Firstly, if the "withs" or partitions between the flues have been improperly built, and holes or cracks left in them, the smoke from the flue in use may penetrate the one complained of, and from that enter the room in which the fire is not burning. This in particular might be noticed if the doors communicating between the two rooms are left open so that the fire could draw air down the unused flue, and with it smoke. This very often occurs, although there are passages and staircase between them, providing there is no fresh air inlet along the route. Secondly, if the two fireplaces communicate in one flue. Thirdly, if the top of the chimney pot of the smoky chimney is below the level (or even level) of those next or near it, the smoke will sometimes be drawn or driven down, especially if there is not a good up-draught, and by your showing there is certainly not. Now for the remedy. If from my suggestions you fancy the first or second is the cause, it is a very difficult and expensive matter, especially the latter, and a simple way to obviate it is to see that the register of your stove fits close, and close it when you do not require a fire. If you have no register, fit a piece of zinc or other material in the opening. The great objection to this plan is that it robs you of the ventilation you get from your chimney, but that can be got over in a variety of ways. If you think the third suggestion is the cause, put a lengthening piece to the chimney pot, or, better still, a cowl. I think, from what you say, that by putting a cowl on the top of your flue, and supplying it with fresh air at the bottom, you will get over the difficulty. I can give you no idea as to the cost; but if you show this to any good tradesman, he will at once tell you about what it would be. The cost of these little jobs vary so much with circumstances.—E. D.

**Harmonium Reeds.**—A. P. (*Renfrew*).—Harmonium and organ reeds are similar in construction; they consist of a plate of metal (zinc) with a slot in the middle, over which a tongue of brass or steel is rivetod in such a manner that it can vibrate easily with a pressure of air applied to it. In harmoniums the wind is *forced* through the reeds, and in American organs it is *sucked* through. The difference in pitch is obtained by varying length and thickness. No one would make either organ or harmonium reeds themselves when they can be bought at such very low prices as at present. It would be a needless waste of time and trouble, and very questionable if the results would be equal to those bought ready made. The voicing and tuning of course are different, and might well be attempted and accomplished by an amateur.—R. A.

## V.—BRIEF ACKNOWLEDGMENTS.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—L. P. B. (*Kew Gardens*); A. F. E. (*London, S.E.*); R. W. A. (*Gray's Inn, W.C.*); H. J. H. (*Hackney, E.*); ONE IN TROUBLE; A NEW READER; W. H. R. (*London, E.*); F. W. S. (*Heathfield*); FAITHFUL READER; R. C. (*Tipton*); AMATEUR; A. B. (*Manchester*); A. J. H. (*Manchester*); C. B.; T. M. (*Southampton*); L. L. H. (*Falmouth*); R. A. (*Sheerness*); IMPORTANT; W. R. (*Manchester*); P. F. (*India*); NAP; J. W. (*Blackpool*); G. H. (*Bacup*; M. W. C. ## Photography for Amateurs.

A Non-Technical Manual for the Use of All.

By T. C. HEPWORTH. *With Illustrations.*

"One of the most thorough and efficient manuals for the non-professional photographer has been written by Mr. T. C. Hepworth. It deals with everything which an amateur should know, not from a hazy, semi-scientific point of view, but from a really practicable standpoint. All the many difficulties which amateurs are likely to encounter, and the many errors into which they are almost certain to fall, are foreseen and provided against, while numerous ingenious hints are given so as to make the amateur's labours as easy as possible. Mr. Hepworth has an intimate knowledge of photographic science, and his book will be welcomed by all amateurs."—*Graphic.*

ARE universally admitted to be worth a Guinea a Box for Bilious and Nervous Disorders, such as Wind and Pain in the Stomach, Sick Headache, Giddiness, Fulness and Swelling after Meals, Dizziness and Drowsiness, Cold Chills, Flushings of Heat, Loss of Appetite, Shortness of Breath, Costiveness, Scurvy and Blotches on the Skin, Disturbed Sleep, Frightful Dreams, and all Nervous and Trembling Sensations, &c. The first dose will give relief in twenty minutes. Every sufferer is earnestly invited to try one Box of these Pills, and they will be acknowledged to be

## WORTH A GUINEA A BOX.

For Females of all ages these Pills are invaluable, as a few doses of them carry off all humours, and bring about all that is required. No female should be without them. There is no medicine to be found equal to Beecham's Pills for removing any obstruction or irregularity of the system. If taken according to the directions given with each box, they will soon restore females of all ages to sound and robust health. This has been proved by thousands who have tried them, and found the benefits which are ensured by their use.

For a Weak Stomach, Impaired Digestion, and all Disorders of the Liver, they act like magic, and a few doses will be found to work wonders on the most important organs in the human machine. They strengthen the whole muscular system, restore the long-lost complexion, bring back the keen edge of appetite, and arouse into action with the rosebud of health the whole physical energy of the human frame. These are FACTS testified continually by members of all classes of society, and one of the best guarantees to the Nervous and Debilitated is, BEECHAM'S PILLS *have the largest Sale of any Patent Medicine in the World.*

## Beecham's Magic Cough Pills.

As a Remedy for Coughs in general, Asthma, Bronchial Affections, Hoarseness, Shortness of Breath, Tightness and Oppression of the Chest, Wheezing, &c., these Pills stand unrivalled. They are the best ever offered to the public, and will speedily remove that sense of oppression and difficulty of breathing which nightly deprive the patient of rest. Let any person give BEECHAM'S COUGH PILLS a trial, and the most violent Cough will in a short time be removed.

Prepared only, and sold Wholesale and Retail, by the Proprietor, THOMAS BEECHAM, ST. HELEN'S, LANCASHIRE, in Boxes, 9½d., 1s. 1½d., and 2s. 9d. each.

Sold by all Druggists and Patent Medicine Dealers everywhere. *N.B.—Full Directions are given with each Box.*

### SOME ODDS AND ENDS MADE DECORATIVE FOR GARDEN PURPOSES.

BY ARTHUR YORKE.

TUBS AND BOXES FOR PLANTS — UTILISING A PARAFFIN CASK—A LARD PAIL—A RAISIN BOX—A SOAP BOX.

THERE is to the properly constituted mind a pleasure in finding a use for things otherwise useless, and in rendering ornamental things otherwise unsightly. I have a few "wrinkles" to offer to those who have a turn for rough outdoor carpentry, which may, perhaps, help them to this state of virtuous satisfaction, and enable them to provide decorative receptacles for plants at a nominal cost. Possibly it may appear to some that more explanation as regards material and methods of working may be desirable; and if so, I must refer such readers to my former articles on "Rustic Carpentry," at p. 247, Vol. I., and succeeding numbers.

*A Paraffin Cask.*—Among the objects suited to our purpose—objects which we shall require to be practically good as new, but to be less costly than the materials of which they are made—the paraffin cask may be mentioned. An ordinary forty gallon cask, standing roughly some 3 ft. high, having a diameter of some 2 ft., and made of good stout oak, costs usually 2s. 6d. I have bought such casks for less money. Sawn through the middle, the paraffin barrel makes two admirable tubs for our work. One such half is shown in Fig. 1. This it is proposed to render suitable for some large bushy plant, so it will have to be mounted on legs. The legs shown are simply so many pieces cut from rough branches. From a heap of stuff one can generally choose pieces sufficiently adapted to the purpose, though their exact contours will, of course, vary. Oak branches, technically known as "bangles," from which the bark has been taken to make tan, will do well; or if the bark is liked, apple-tree or elm boughs will be suitable. That these sticks should be rough, and gnarled, and knotted adds to their effect.

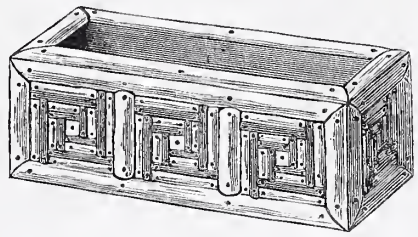

Fig. 4.—Window Box made from Raisin Box.

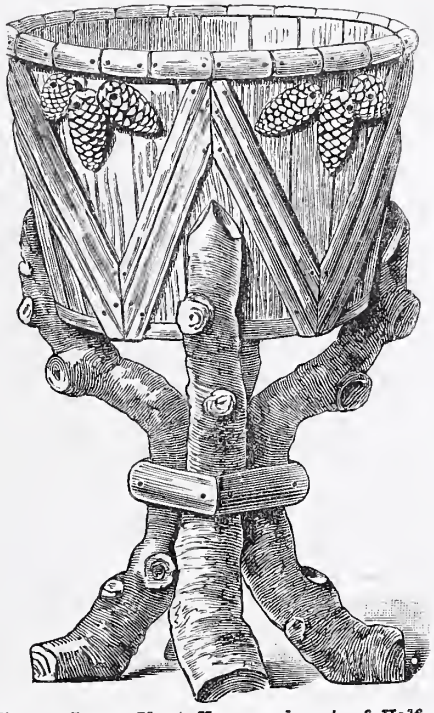

Fig. 1.—Large Plant Vase made out of Half a Paraffin Cask.

But as the tub will be only partly covered with rustic mosaic work, it will be well before nailing anything upon it to paint it. A good dark brown or chocolate will go well with the natural bark; and, after painting, we can fix on our decoration of split rods. These will have to be cut through with the saw, the lengths being too great to be safely split with the hatchet—that is, with the exception of those round the lip, which are of thicker rod than the zig-zags; say, 1½ in. as compared with 1 in. In the zig-zags the light central strip is supposed to be of peeled withy, the darker ones on each side having the bark on, and being probably of hazel. Generally speaking, wrought brads are to be recommended for fixing rustic mosaic, but where, as in the present case, the strips have to be bent over a curved surface, small wire nails will be found more secure. Groups of fir cones, as shown, will prettily ornament the triangular spaces.

Fig. 2 gives the other half of the cask arranged for, say, a dwarf shrub, an orange-tree, or the like. In small town or suburban premises, such tubs are specially useful where there is a back court into which anything green cannot otherwise be introduced. In this, it will be seen that by way of variety the tops of the staves have been sawn to a zig-zag line, which is followed a little below by a moulding of split rods. Half-way between this and the bottom a band of mosaic is arranged in light and dark strips—withy, that is—and hazel. The bits filling the diamond-shaped centres of this pattern are cut from thicker stuff than the rest, that they may project as

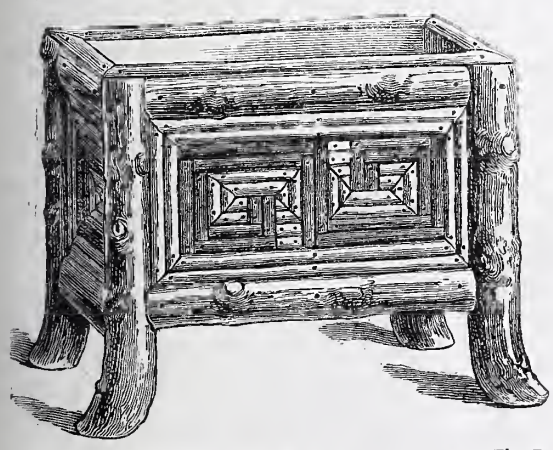

Fig. 3.—Large Garden Plant Stand made from a Soap Box or any other Strong Box.

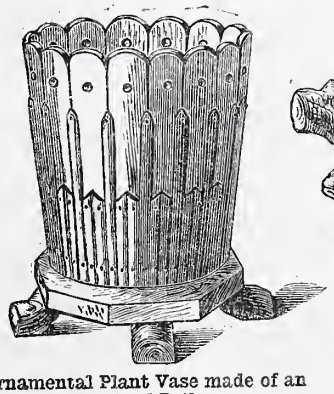

Fig. 5.—Ornamental Plant Vase made of an American Lard Pail.

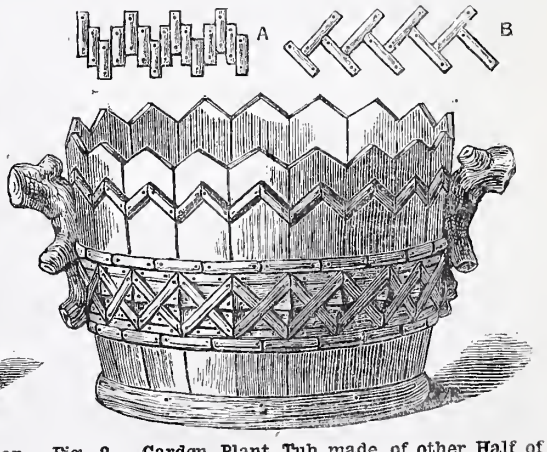

Fig. 2.—Garden Plant Tub made of other Half of Paraffin Cask—A, B, Alternative Modes of Moulding.

bosses beyond the general level. Over the unavoidable iron hoop at bottom, from which place short strips would, if nailed, be often detached, a rough "dry-cask" wooden hoop has been fixed. At the sides two pieces of rough branch stuff have been placed to serve as handles, and to resist strain these should be secured from within by strong screws.

*A Lard Pail.*—Fig. 5 is intended for a somewhat low-growing flowering plant—say, a large bushy geranium. In its original character this was nothing more dignified than an American lard pail, value 9d. to 1s. As in the last tub, the staves have been sawn to a more ornamental outline; they have also been perforated.

On this the ornamental strips of split rod have been arranged in straight vertical lines, to avoid the difficulty of bending and keeping them in place if bent round so small a vessel. The bottom of the pail is screwed down to an octagonal slab of wood, to the under side of which four short bits of rough bough are nailed as feet. As neither this nor the last tub are wholly covered with mosaic, they should, of course, first be painted. The slab at bottom will look very well left rough, as shown, but if painted it will be improved by strips of split rod nailed round its edges.

*A Raisin Box.*—Nor are some of the boxes which we can get from the grocer badly suited to our purposes. Such boxes are not costly, and to buy and knock these up for rough uses is often more economical than buying new material. A box, being straight-sided, is more easily ornamented with rustic work than the curved sides of a tub, but we must take care that the boards are stout enough to hold the brads firmly. Fig. 4 is a raisin box. That before us is about 21 in. by 7 in. by 7 in.—dimensions which lend themselves well to decoration. Two or three of these ranged side by side are not bad for the window-ledge. This box will be seen to be wholly covered with mosaic of dark and light strips in panels. Strips are also nailed on the upper edges.

*A Soap Box.*—In Fig. 3 we have a larger box, probably, a soap box. This, besides being completely covered with rustic work, has been mounted on legs. The easiest way to fix one of these legs on is to saw the piece of stuff in half to a distance from top equal to the depth of the box, and then to cross-cut and remove one half. The corner of the box will be brought to the middle of the cross-cut, and the leg nailed on to the *side* of the box. The piece which has been sawn off will then be cut through (quartered), and the proper quarter replaced and nailed to the *end* of the box. Frets, such as those shown in these two examples, are patterns of a kind well adapted to be worked out in rustic mosaic.

## XYLONITE AS A MATERIAL FOR FRET-SAWYERS.

BY D. DENNING.

Ease of Working Xylonite—Plain Open Fret-work—Laying Patterns—Polishing—Glue and Cement—Making up—Overlays—Thick Inlays—Inlaying in Xylonite Veneers—Preparing the Sheets—Making up Inlays—Cleaning — Finishing — Mounting Transparent Xylonite.

In page 787, Vol. II. of Work (No. 101), is an article directing the attention of readers to the wonderful material known as Xylonite. In it mention is made of its use to fret- and marquetry-cutters, and as there is good reason to know that a very large number of readers of Work are interested either professionally or as amateurs in fretwork, no doubt a few practical suggestions on the use of xylonite for their special craft will be welcome. I have purposely not referred to our readers as marquetry-cutters, for the fact is this beautiful and artistic art is not practised to the extent it might be by amateurs who are proficient in manipulating the fret-saw. That many try inlaying with one or even two colours cannot be denied, but this kind of work is by no means on an equality with marquetry. One reason that may operate against the popularity of this art as a pastime not only for men, but for women, is probably due to the scanty information of a practical kind which has been published. Another, and the one which is more immediately connected with the subject of this paper, is the difficulty in working with the materials used. These, as is well known, are wood veneers, and those fret-sawyers or would-be marquetry-cutters know equally well that if they have tried to make inlays with them according to the instructions generally given in handbooks on the subject—viz., by gluing alternate sheets of paper and vencer—that they have signally failed. Even if the veneers, being brittle, have not broken while they are being sawn, they have done so when an attempt has been made to separate the various layers. I am far from saying that ordinary veneers cannot be used with success for inlays of two or three colours, but still they require tender handling, for there is no getting away from the fact that they are easily broken, and it is almost a matter of impossibility without considerable skill to manipulate small pieces, perhaps not $\frac{1}{16}$ in. wide, without breaking them. In any case, with the ordinary treadle machine, even with such a good one as the Britannia Company's No. 8, it is difficult to cut them without annoying fractures happening. This must be the case with any material which has a grain like wood or is brittle.

Now xylonite is free from these objections, or rather, I should say, from these properties, of wood. It therefore offers an excellent material for the amateur or occasional marquetry-cutter, as little beyond capacity to saw accurately and to a line is necessary. For similar reasons the inlayer using only two colours will find it an admirable material.

Before, however, proceeding to give any hints to these more advanced workers, the plain fret-cutter must not be forgotten or overlooked.

As stated in the article already alluded to, xylonite is to be had in a great variety of appearances, so that the fret-worker can take his choice as to colour, etc. In the actual working there is no practical difference between any of them. Malachite, ivory, amber, etc., etc., are all cut and manipulated with equal ease, so that the appearance of the material has nothing to do with its treatment.

On a No. 8 machine of the Britannia Company I have cut xylonite of the greatest thickness in which sheets are made—viz., 1 in.—with ease, so that any thickness may be considered workable. Of course, few will care to use it so thick as this for fretwork. Indeed, for this purpose a thickness of $\frac{1}{8}$ in. is probably the most suitable, as, owing to its value, only small things are likely to be made from it. When little things are made of fretwork, we all know how liable they are to get broken; but if made of thin xylonite, they are even more durable than if made of comparatively thick wood.

The material requires no special treatment in sawing, and is bored and worked in the usual way. It is, however, so soft that those who are accustomed to work in hard wood must be on their guard that their work does not "run away" with them, which simply means that xylonite must be treated with a light hand and fed gently to the saw. I am assuming that this is worked with a machine, but the same broad rules apply with a frame. Those who are accustomed to fret-sawing will understand me when I say that two sheets of, say, $\frac{1}{8}$ in. thick can be cut together as easily as one; in fact, I am not sure that I do not prefer to cut through a thickness of $\frac{1}{4}$ in., as this is more rigid. This thickness can easily be cut with a No. 1 blade, but there is no reason why a larger should not be used, as the material cuts so cleanly that even a No. 5 or No. 6 will leave smooth edges, without any rugged "burr," of which there can be none.

If edges want trimming at all afterwards to remove irregularities caused by faulty sawing, the ordinary small files may be used, but they are not necessary, as the blade of a penknife may be used with almost greater ease and advantage either to cut or to scrape.

Perhaps something should be said about laying the patterns on xylonite. I find the best way is to stick them on with ordinary flour paste—at least, this is as good an adhesive for the purpose as any, though I sometimes use glue. The paper remaining can easily be washed off without the trouble of rubbing with glass-paper, as water does not affect xylonite. A piece of fret can therefore be laid in some till the paper comes away without trouble.

As the sheets are not polished, nor yet perfectly smooth, when supplied, the frets must be finished off afterwards—first by smoothing, and then by polishing. To make the surface uniformly smooth, glass-paper of varying degrees of coarseness may be used, the finest, of course, being last. The polishing is best managed by means of a calico wheel or buff, with pumice powder and oil in the first place, and then finely powdered whiting with just enough oil to prevent the dust flying about. Unless a good deal of the surface has to be removed, it will be seen that the pumice powder renders the use of glass-paper or scraper unnecessary. It is not, however, every amateur who has a suitable wheel, and even if he has a lathe to which one might be attached, he may not care to run the risk of damaging it with the pumice. Those who cannot do their own polishing will be glad to know that the Xylonite Company will do what is necessary at a very moderate charge, and, from having experienced assistants at this kind of work, they certainly put a better finish on than could be managed by those who are inexperienced. I certainly recommend those who have made anything they value to send to the manufacturers, as the small cost incurred is neither here nor there when the improved appearance of the work is taken into account. Fretwork articles should be sent in pieces, and not made up.

Those who do not care to go to this trouble or expense may be glad to know that small pieces of xylonite may be polished fairly well by rubbing them on a piece of cloth stretched over a board instead of a calico wheel. The labour, however, is somewhat considerable, and the result not altogether satisfactory.

It will be noted that the polish is got by

friction only, and not by the application of a varnish of any kind. In connection with this, I may say that French polish should not be used on xylonite, the manufacturers of which make a special varnish which is sometimes used on common articles by themselves. They inform me, however, that they are willing to supply it in small quantities to myself and friends, who for present purposes may be regarded as including all readers of WORK. The varnish can be applied by anyone, and to forestall inquirers in "Shop" as to its ingredients and the way it is made, I may as well say that I cannot tell, for it is a trade secret which, in the interest of the manufacturers, it would be unfair to divulge. Readers who are acquainted with me know my opinion generally on "trade secrets," but to explain this one would be a breach of confidence; therefore nothing more need be said in excuse for my reticence in the present instance. Possibly some readers may be able to concoct or find some varnish suitable for the purpose; but if they take much trouble in doing so, they will be "penny wise, pound foolish."

When making up articles of fretwork, it will be well to note that though soft edges, etc., cannot easily be shot in the ordinary way with the plane, if this is very finely set they may be, but ordinarily it is easier to do what is necessary by filing or grinding. Another important matter that must not be overlooked is that glue is not suitable for joining pieces of xylonite. Possibly india-rubber cement might do, but the best adhesive is undoubtedly that used by the manufacturers themselves. It is a liquid, and is applied like ordinary glue, but care should be taken not to apply it too thickly if a neat joint is required, nor yet to let it get on any polished surface. It is made in two forms—opaque white for white material, and clear for others—and may best be described as a liquid xylonite. It will be supplied in small quantities to my "friends," and the remarks in connection with the varnish may be applied also to the cement. It seems to act rather by partially dissolving surfaces to which it is applied, and so causing union, than mere adhesion. On this point I cannot, however, be certain; but the stuff is most tenacious, whatever its precise action; it dries very quickly.

Overlays of fretwork are not very easily laid with glue alone; though, if only a slight hold on the wood is required, glue may answer, especially if aided by a few needle-points. Glue, however, is apt to flake off from xylonite, so that the adhesion cannot be depended on. A better way is to coat the back of the fret with the special cement and to touch the wood here and there with glue, and for this purpose I prefer Le Page's to the ordinary kind. A still better plan is to coat both the back of the fret and the surface of the wood with the cement, and then bring them together under pressure. The appearance of the wood is very little altered by the cement, which goes further if size has been previously used.

As $\frac{1}{4}$ in. can be cut easily, I have fastened two pieces together to make this thickness with small wire nails in the waste, a piece of thick paper being between the xylonite. This has been fretted in the usual way, so that the paper gives a perfect pattern. By sticking this afterwards on another piece of xylonite it has been used to cut the pieces for inlaying into the other. This is approaching very closely to the method of marquetry cutting, inasmuch as the pieces to be inlaid are cut separately, so that objectionable drill-holes are not observable, all points and corners being preserved in their integrity. When sticking the cut-through paper pattern, care must be taken that it is not stretched, as, if it were, the pieces, however accurately cut, could not fit properly without a good deal of filing and cutting. If the glue be applied to the xylonite, and the paper laid flat down on it, I have not found any difficulty from the paper stretching as would be the case were glue or paste to be rubbed on the paper. May I remind readers that the width of the saw kerf must be allowed for when cutting the inlay pieces, so that it would not do to saw within the paper on the bare material? The saw should cut through the paper just at the edge, so that none of it is on the inlay pieces. By this means the saw-cut or kerf is entirely in the waste, which in this case is the reverse to what it was in the original. Of course, to manage this plan, it is presupposed that the sawyer has considerable skill in cutting accurately to a line. For the beginner to attempt it would simply mean a waste of good material, and he had better adhere to the time-honoured plan of cutting both pieces through at once. By the plan advocated many little nicknacks in which both sides show, such as paper-knives, can be made in duplicate, not only so far as pattern is concerned, but also in colour of material, with the smallest possible amount of waste. With such inlays, it is not necessary to stick them on paper while inlaying. It is sufficient to touch the edges with the xylonite cement. As it may happen that the two materials, say ivory and tortoiseshell—of course, I refer to the imitations of the substances—which have been combined as an inlaid piece of work are not of exactly the same thickness, the surface must be made level. This may be done with glass-paper, but it is a tedious job, and I have found nothing better for the purpose than an ordinary cabinet-maker's scraper, well sharpened. If it is blunt, it is bad enough on wood, but on xylonite it is worse.

For ordinary inlaying in only thin stuff which has to be mounted on a backing of solid wood, xylonite of about $\frac{1}{25}$th in. does as well as anything. By the way, I may here state that this thickness would be expressed by the manufacturers as $\frac{4}{100}$ths of an inch, as they have in this respect adopted the decimal system, with the inch as the standard unit.

This thin or veneer xylonite may be cut in the manner common to marquetry-cutters, or it may be simply cut through several sheets at a time, after the plan usually practised by amateurs. In either case, the great advantage xylonite has over wood is that the finest fret can be done in it without danger of breaking. I am now engaged on an elaborate piece of work, consisting of tortoiseshell and ivory alternately, and, as a description of my plan may be useful, here it is. I have no "trade secrets," and my methods are at the disposal of all readers of WORK. If they can find better, perhaps they will be good enough to send on explanations to the Editor. I am using the thin material mentioned above, with a No. 8 Britannia machine and No. 1 saws of the ordinary kind. Five thicknesses are cut through at a time, so that for each set of panels prepared there are two of tortoiseshell inlaid with ivory, and two "counters" of ivory inlaid with tortoiseshell. The fifth sheet is waste, unless I afterwards use it as an overlay. It should perhaps be mentioned that for the article in question I require two panels of each pattern, otherwise only three sheets would be cut through at a time.

The panels having straight edges are cut from the large sheet of xylonite, by scoring it with the point of a penknife, guided by a straight-edge. When partly cut through, the stuff can be split at the cut. By this means the trouble of sawing is avoided, and straight, clean-edged pieces are got at once. The sheets are then glued together alternately, the top and bottom one being of the same material, which, in this instance, is ivory. Between each two is a sheet of paper, as I find they hold better than when glued directly to each other, and the paper allows the small pieces to be separated more easily than they otherwise would be when they are to be inlaid. The glue is put all over, and not merely in patches, so that when the sheets have been kept together by pressure till the glue is dry, which takes some time, they form a good solid block which is very pleasant to cut. In sawing, the "tilting table" is made use of to a slight extent, and though many parts of the pattern are little, if any, more than $\frac{1}{16}$th in. wide, while some are less, I have not had a single mishap in the way of the material breaking or tearing with about a dozen panels, each containing from fifty to seventy holes. This could not be said if ordinary wood veneers had been used, for if some of them had not been broken while sawing, they certainly would at some subsequent part of the process, such as when separating the sheets. This I do by putting the block in water till the sheets come apart, or by inserting the blade of a knife between them, and afterwards washing the paper off.

They are then ready for inlaying. The little pieces, of course, are all in their proper order and in blocks of five thicknesses just as they were sawn out. On a sheet of paper in front of me are the four frets, the top one having been discarded by now, as it has served its purpose, which is merely to allow of the small pieces to be let into the sheet next in order being cut from it. As each block of the small inlay pieces is taken up, the corresponding opening for it has some glue daubed down in it, and each small piece, easily separated from the others either with the thumb-nail or a penknife blade, is pressed down in its place. A quantity of glue oozes out, and by the time the inlays are done the sheets present anything but an inviting appearance. This, however, is of no consequence, and the next thing to be done is to clean off all the glue and waste paper. This is managed by putting the sheets on a smooth, flat surface, with the papered sides downwards, and then washing them with a rag or nail-brush. This, of course, not only removes the glue, etc., from the surface, but also from between the pieces, and some care must be exercised not to wash away small pieces. If any do get accidentally displaced, they are easily put back. Although thoroughly wet, the inlaid panel with the paper under it can easily be raised and turned over without injury, when the other side can be washed in the same manner. Superfluous moisture is now removed, and a sheet of glued paper is stuck down on the panel. It can now be handled with impunity, and be laid aside to dry to be mounted on solid wood. This is done in the usual way, the only slight differences with xylonite being that it is not necessary to go over it with the toothed plane. It is stuck down with the cement or solution already referred to applied to the inlay, and ordinary glue to the wood. To ensure perfect contact, the sheets of

xylonite should be laid with a caul. After adhesion is perfect, the paper may be removed with a damp rag, but, to prevent the glue being injured, the quantity of water should not be so great as before. After this has been done, the inlay can be finished off by polishing, with perhaps a preliminary touch or two with the scraper to level it thoroughly. If any small bits get accidentally lost, as they sometimes will, the ordinary stopping of resin and wax does admirably for deficiencies in the tortoiseshell, while plaster of Paris or whiting answers the same purpose for the ivory.

The reason why it is recommended that the sheets should be stuck together all over while being sawn, and not merely fastened here and there, is that the burr caused by the drill on the under surface of each is objectionable, and, altogether, loose sheets are not so pleasant to cut as when they form a solid block.

By adopting the simple means described, any tolerably skilful fret-cutter may aspire to make things of greater beauty and artistic value than he has probably had any idea of when working in wood alone.

It may be a useful hint to the inlayer or marquetry-cutter using xylonite that the beauty of tortoiseshell, amber, and other transparent or semi-transparent substances, is partly lost unless they are laid on white background. As it is not always convenient nor suitable to the article to mount them on white wood, the desired result may be obtained by having a piece of white paper between the ground and the inlaid sheet of xylonite, which, of course, has thus a white backing given to it.

I trust these remarks may have not only the effect of inducing fret- and marquetry-cutters to try a charming material which seems specially adapted to their requirements, but also of enabling them to use it with some degree of certainty, instead of having to find out the best treatment by experiment. That the subject is exhausted I do not pretend, but the points on which the amateur or professional worker is likely to require information have, I think, all been attended to. If anything essential has been omitted, I shall be happy to answer inquiries in "Shop"; but please do not ask me to explain how you can make your own xylonite at home, for it cannot be done.

## A FOLDING PLATE DRAINING RACK FOR PHOTOGRAPHERS.

BY CHARLES A. PARKER.

SIZE OF PLATE DRAINING RACK — PREPARATION OF THE LEGS—CUTTING THE REBATES TO TAKE BARS AND STAYS—CROSS BARS—PUTTING TOGETHER TWO HALVES OF RACK—HINGEING RACK TOGETHER—CUTTING AND ATTACHING V-SHAPED GROOVING TO COMPLETED RACK.

AN amateur who has attained some little proficiency in the art of wood-working, and can manage to put together simple framing, generally experiences a desire to lessen the cost of his photographic requisites by constructing some of the less important items himself, as there are many articles that constitute the paraphernalia of a photographer that are not only expensive when their simplicity of construction is taken into consideration, but which come well within the scope of the amateur workman, without involving such manual labour as would be apt to lead to failure. A folding plate rack, which is shown in Fig. 1, is an indispensable dark room accessory that can readily be made by any amateur woodworker in a very short space of time. The size described below is such as is usually employed for 3¼ by 4¼ in. or 5 in. by 4 in. plates, but it may best be said that a rack suitable for half or whole plate negatives can be constructed by simply adding a couple of inches to the length of the legs below described. From an ½ in. board—preferably a piece of straight-grained yellow pine—cut off four narrow strips ¾ in. wide and 7 in. long, with one end of each strip sawn off to an angle of 45°, this latter being done on a mitre-cutting board. The other end of each strip will now require to be rebated, as shown in Fig. 2, the length of the rebate being 1¼ in., and the depth ¼ in. The simplest method of cutting this rebate is to make a saw cut, ¼ in. deep, at the above distance from the end, as shown at A to B, Fig. 3, and another from C to B, which will thus remove the requisite amount of wood. These pieces, which are intended to form the legs, may then be placed aside while a couple of cross bars are being prepared to fit across the rebated portions of the legs for the purpose of uniting them. These may be cut from a strip of ¼ in. board 1½ in. wide, one of them being 9 in. and the other 10 in. in length. When ready, take two of the legs first prepared, and glue one of them at each end of the 10 in. strip, using a couple of ½ in. brass screws to each leg, and after these have been fixed in position, glue and screw a thin strip of wood, ½ in. wide, across from side to side, in the position shown in Fig. 4, placing this stay at 4⅜ in. from the upper end of the limb. The other cross piece and the two remaining legs are then screwed together in a similar manner, except that this limb will not require a stay to be placed across, as in the case of the other. The two limbs are now placed together in the position they are intended to occupy when the rack is closed; after which they are hinged in the middle by driving a ¾ in. round-headed brass screw through the side of each outer limb, at a distance of 4 in. from the top of the rack, as will be understood by reference to Fig. 5, which represents the rack when closed. Upon opening the rack, it will be found that the strip of wood placed across the lower portion of the outer limb forms a stay which prevents it from being opened too wide, and likewise renders it rigid when in use. When the rack has been fitted together in the manner above described, the upper portion of each limb must be furnished with the grooves to hold the plates. Suitable grooving wood can be purchased from most photographic dealers at 10d. per foot for 11 in. wide. Should any difficulty be experienced in obtaining the grooving, it will be found an easy matter for the reader to cut sufficient for this rack. In short, the reader is strongly advised to adopt this course, as the grooving supplied by the dealers being specially intended for plate boxes, is therefore scarcely suitable for our purpose, owing to the grooves being formed thus: U, instead of the V shape recommended; consequently, a freshly-developed negative in careless hands would stand a good chance of getting the thin edges torn or damaged. Take a piece of ⅞ in. board 8 in. wide, and saw off a couple of 1¼ in. strips across the grain, afterwards gluing these into the upper portions of each limb of the rack; and when the glue has set, proceed to cut a series of twenty-four V-shaped grooves by means of a sharp 1½ in. chisel, a saw, or a knife, having previously marked out the exact position of each groove on the edge of the wood, so that they may exactly correspond. The grooves for the inner limb of the rack occupy the full length of the space, which is 8 in.; but for the outer limb, which measures an inch more in length, there will be ½ in. plain space at each end before the grooves commence, as is clearly shown in Figs. 1, 4, and 6. When the grooving has been provided, the rack will be finished, thus completing a very useful article on which to place negatives out of harm's reach after the operations of washing or varnishing.

## THE ACCURATE DRAWING OF SCREWS.

BY P. B. H.

HOW TO DRAW A SINGLE V-THREADED SCREW, A DOUBLE V-THREADED SCREW, A SINGLE SQUARE-THREADED SCREW, A DOUBLE SQUARE-THREADED SCREW, A DOUBLE SQUARE-THREADED NUT (IN SECTION).

IN WORK, No. 109, I finished by showing how a spiral line was drawn round a cylinder, and with a promise to show how the threads of a screw are drawn accurately.

As a first example, Fig. 14 shows the ordinary single V-threaded screw, 1½ in. diameter. Now, if we turn to a table of Whitworth threads, we find that a screw of the above diameter has six threads to the inch—that is to say, the pitch, or the distance between two threads, will be ⅙th of an inch.

Draw a horizontal line, A B, as a base from which to commence. On this line, slightly to one side (the left hand preferably) of where the screw is to be drawn, set up a vertical line 1½ in. long (this height

depends altogether on the length of bolt to be drawn), and, commencing below, set off distances on it equal to the pitch—that is, $\frac{1}{8}$th of an inch, which will exactly divide the line into nine equal parts. Subdivide these divisions into $\frac{1}{2}$, $\frac{1}{4}$, and $\frac{1}{8}$, as shown, making a small vertical scale. The number of divisions the pitch is divided into is not arbitrary, but always let them be even in number. For this pitch of screw, eight divisions are ample, more being scarcely distinguishable. Number the pitch divisions on the scale 1, 2, 3, etc., as shown.

Now, a short distance to the right of scale, and following instructions given in describing Fig. 3 (p. 70), design the outlines of a V-thread $\frac{1}{8}$th of an inch pitch, commencing with the exterior angle (*c*) of the thread on the line A B. Of course the points *d*, *f*, etc., can be projected by the T-square from the scale. Having done this, from the line *a a*, passing through the extreme rounded portion of the thread, set off $1\frac{1}{2}$ in. to the right. This will be the diameter of the bolt. Construct here the outlines of the V-thread similar to the one on the left; but care must be taken that the exterior angles do not come *opposite* those on the left side, but *midway* between them. This can be easily done by projecting lines across from the $\frac{1}{2}$, $1\frac{1}{2}$, $2\frac{1}{2}$, etc., divisions of the scale on to the line $a^2$ $a^2$—these will give the vertical position of the angle points of the threads. The reason is, that in single-threaded screws, in winding once round the body, the V rises from *c* to *e*, therefore, when it gets half-way round (that is, to *d*), it will have risen half the distance *c e*—that is, one-half the pitch.

Having drawn the outlines of the thread on both sides, it is now necessary to obtain the path of the line joining them. To do this, we must proceed almost in the same manner as we did in Fig. 1. Below A B draw two concentric semicircles centrally below the bolt, one being the same diameter as the bolt, the other as the bolt at the bottom of the threads. Divide these into four equal parts—the divisions of the outer circle being numbered *a*, $a^1$, $a^2$, etc.; those of the inner one, *b*, $b^1$, $b^2$, etc. From all these points set up perpendiculars, *a a*, $a^1$ $a^1$, *b b*, $b^1$ $b^1$, etc. As all the lines, *c d*, *e f*, *h i*, *k l*, etc., follow one and the same curve, I have shown the construction lines for *k l* only. I have done this to prevent confusion, as in the lower part of the figure I show the path of the spiral, which is unseen. To proceed, then: the point *k* is

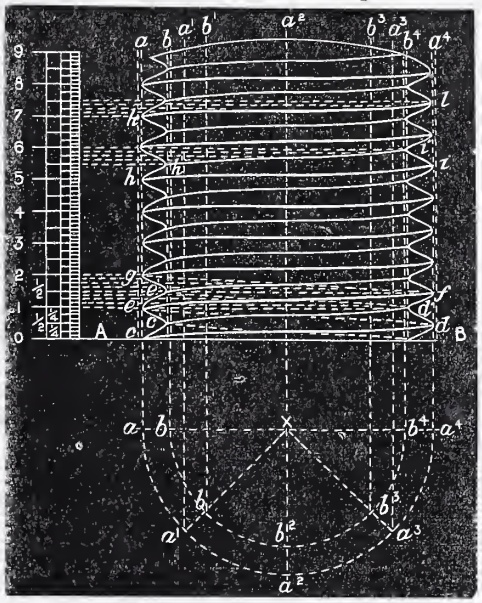

Fig. 14.—Single-Thread V-Screw ($1\frac{1}{2}$ in. diam.).

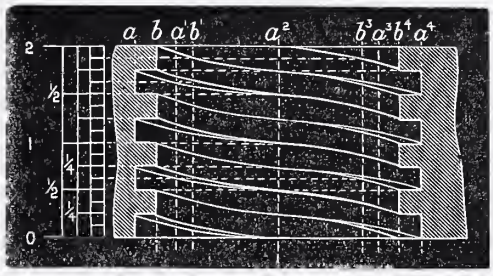

Fig. 18.—Nut for Double Square Thread Screw.

$a^2$ $a^2$, will give another; and from $7\frac{3}{8}$, cutting $a^3$ $a^3$, will be another. A line drawn by hand from *k* to *l* through these points will give the path of the thread at the circumference of the screw. The same method can be followed for the bottom of the thread, $h^1$ $i^1$, but in this case the horizontal lines from the pitch must cut the vertical lines drawn from the points of division on the smaller semicircle, which is equal to the diameter of the bolt at the bottom of the thread—that is, wherever the horizontal lines from 6, $5\frac{7}{8}$, $5\frac{3}{4}$, $5\frac{5}{8}$, and $5\frac{1}{2}$ cut the vertical lines $b^4$ $b^4$, $b^3$ $b^3$, $b^2$ $a^2$, $b^1$ $b^1$, *b b*; these are the points through which the spiral line must be drawn from $h^1$ to $i^1$.

I also show the construction lines for obtaining the spirals as they wind behind the screw from *f* to *g* and $d^1$ to $e^1$ respectively. I shall not describe these; I shall presume that my readers will be able to understand them with a little thought.

Fig. 15 shows a double-threaded V-screw, to draw which we proceed as in Fig. 14. A scale similar to that one will be found convenient, but as a second thread now winds round between the first, the pitch of the thread must be doubled to allow of this, and as each thread will now rise double what it did at first while travelling the same distance, the pitch must be doubled too. Therefore, draw the pitch on the scale equal to $\frac{1}{4}$ of an inch, and divide it into eight equal parts as before. Now, though we have doubled the pitch, we must still keep the size of the thread the same as in the preceding figure; we must not design it again from the increased pitch, according to Fig. 3 (p. 69). Draw the left-hand side of the screw exactly the same as in Fig. 14, commencing with the angle of the thread, *c*, on the line A B. Now, as there are two threads, one will always be half the pitch in advance of the other—or, we will say, half a revolution; therefore, the point *l* will represent the commencement of the second thread, being half the circumference from *e*. It will thus be seen that, contrary to the preceding Fig. 14, the exterior angles of the threads come exactly *opposite* each other in this case, and not *midway*, as in the last case. Having drawn all the outlines of the threads, draw all the construction lines and semicircles as before, lettering them the

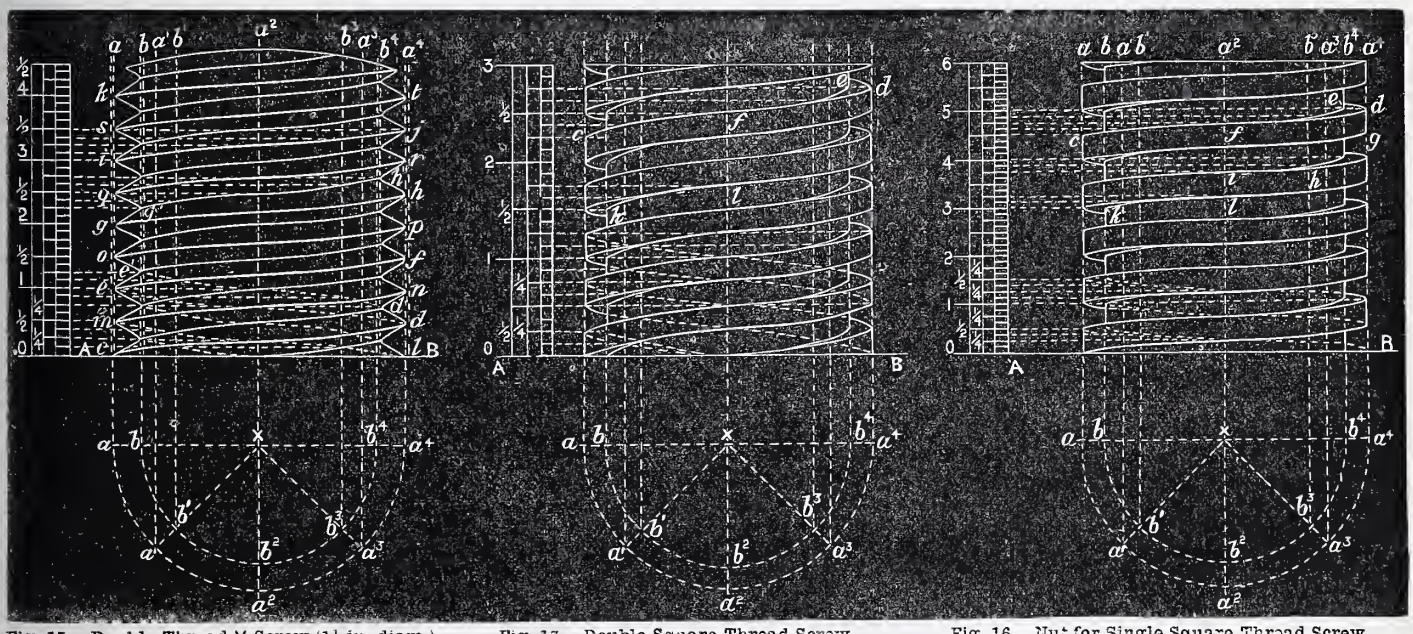

Fig. 15.—Double-Thread V-Screw ($1\frac{1}{2}$ in. diam.).

Fig. 17.—Double Square Thread Screw.

Fig. 16.—Nut for Single Square Thread Screw.

opposite 7 on the scale; the point *l*, half the circumference of bolt, is opposite $7\frac{1}{2}$, which is half the pitch. Draw dotted lines from those points to *k* and *l* respectively. A line from $7\frac{1}{4}$, cutting the line $a^1$ $a^1$, which is drawn from the point $a^1$, $\frac{1}{8}$ of the circumference of the bolt, will be a point in the curve wanted; a line from $7\frac{1}{4}$, cutting

same. I have marked the one thread commencing at *c* by the consecutive letters of the alphabet at the exterior angles, as—*c*, *d*, *e*, *f*, *g*, etc.; the other, commencing at *l*, as *l*, *m*, *n*, *o*, *p*, etc., so that the reader will not get confused. I have shown construction lines for obtaining the spirals, and I think no further explanation of Fig. 15 will be necessary.

I might here remark that, having once obtained by construction the spiral line, *k l*, the other similar lines might be drawn by the aid of a French curve, if a part thereof could be found to exactly coincide with the line. If a piece could not be found to coincide with the whole of the curve, there would be no difficulty in finding a part for the half of the spiral. In this case it would only be necessary to mark the point on the centre line, $a^2$ $a^2$, where the spirals cut it; when, after drawing the halves of the similar spirals down one side, turn the drawing round, and reproduce the others by the same piece of the curve, as they are the same, only reversed. This applies to the spiral, $h'$ $i'$, Fig. 14, and all the similar lines, as well as the spirals in Figs. 15, 16, 17, and 18. This, of course, reduces the labour vastly, and where time is short, it is a necessity to use this method. But for a beginner, I should advise drawing them all out by the construction lines for practice, and also to a bigger scale, with more divisions in the pitch and semicircle.

We now come to Fig. 16, which shows a single square-threaded screw of the same diameter as the preceding ones. Generally, the pitch of a square-threaded screw is double that of a V-thread of the same diameter. In this case I have, however, only taken it at ¼ of an inch, so that there will be more threads to draw, which will, I hope, be of some benefit to readers.

Set up the scale on A B, as usual, dividing the line into six equal parts, or ¼ of an inch each, equal to the pitch. Divide each of these again into eighths as before. Now, slightly to the right, set up two lines, *a a* and $a^1$ $a^1$, 1½ in. apart, which is the outside diameter of the bolt. If we now return to Fig. 4 (p. 69), we shall see that the depth of a square-threaded screw is $\frac{1}{40}$, or rather less than one-half the pitch. This, as stated, is ¼ of an inch, therefore, the half will be ⅛ of an inch: so now draw two vertical lines, *b b* and $b^1$ $b^1$, within the first two, and distant from them a shade less than ⅛ of an inch. These two lines will give us the body of the screw.

Draw two semicircles below the line A B—one equal to the outside diameter, the other to the body of the screw. Divide these as in the two preceding cases, and also the construction lines.

Now, as half the pitch is for the thread and half for the space, divide the lines *a a* and $a^1$ $a^1$, commencing on A B, into eighths of an inch. Take notice that on the left-hand side a thread is at the bottom, whilst on the right-hand there is a space; the reason has been explained in Fig. 14.

We will now proceed to draw the spiral line joining *c*, *d*, which points have already been obtained by projecting lines from 4½ and 5 on the scale, to cut the lines *a a* and $a^1$ $a^1$ respectively. The points where the lines from $4\frac{5}{8}$, $4\frac{3}{4}$, and $4\frac{7}{8}$ cut, the vertical lines, $a^1$ $a^1$, $a^2$ $a^2$, and $a^3$ $a^3$, will give the intermediate points through which the spiral line joining *c* and *d* must pass. This can be drawn by hand, and at *d*, and any other similar places where the spiral can be seen turning upward or downward, there should be a small curve—or, I might say, there should not be an angle. The line should follow round in a short curve.

It will be seen that as the thread is always vertical to the centre line of the screw, the point *e*, where the spiral winds round the body of the screw, will be exactly opposite *d*—that is to say, where the line drawn from 5 on the scale to *d* cuts $b^1$ $b^1$ will give the point E, and the spiral drawn from it will gradually merge into the spiral *c d*, till at *f* it appears as the same line. To show this more clearly, take the lower thread; draw a line from 4 till it cuts $b^1$ $b^1$: this gives the point *g*; draw also from $3\frac{7}{8}$ to cut $b^3$ $b^3$, which it does in *h*; the line from $3\frac{3}{4}$ cuts $a^2$ $a^2$ in *i*—this latter point is the same as for the exterior spiral as well. This can now be drawn by hand. Now draw *k l* in the same manner as *g i*. Either in this way, or by means of a French curve, all the spirals can be drawn. I have shown the construction lines for the different spirals running at the back of the screw. No description will be necessary, I think.

Fig. 17 shows a double square-threaded screw of the same diameter as the last, the size of the thread being the same. The only difficulty is that the pitch is now double, and that a second thread now runs between the first one. The pitch, as will be seen, is from the bottom of one thread to the bottom of the next but one. I have shown the construction lines for each different curve, and lettered them as before, so I shall leave the reader to make it out for himself: which I think he will be well able to do by a careful study of the two preceding figures.

Fig. 18 shows the *section* of a nut to work on the screw, Fig. 17. This will, no doubt, strike the reader at first sight as looking rather peculiar: the threads here rising from the right to the left hand, instead of from the left to the right, as in the bolt; and this gives a deceptive appearance to it, and leads us to believe that it has been drawn wrong. The reason is that the nut being in section, the threads in it really fit the dotted threads, or those at the back of the bolt. These threads are drawn with the same pitch and construction lines as the last figure—in fact, with the exception of a new scale, the same construction lines produced serve for the nut as well as bolt.

Being double-threaded, the pitch is greater than in Fig. 16, so that the lines for obtaining the spirals corresponding to *e f*, *g i*, and *k l* in that figure come out more distinctly both in the nut and bolt. Another peculiarity is that in the nut the longer spirals now vanish behind, or merge into the shorter ones. I shall again draw the construction lines for the spirals, and leave them to explain themselves by the aid of a small amount of thought.

I may here state that a V-threaded nut will be obtained by the use of the same principles. From these last five figures, if well grasped, there will be no difficulty in fixing the points necessary for drawing the screws in Figs. 10, 11, 12, and 13 (p. 69).

I shall make no apology to my readers for the length of this paper, as I have intended it for beginners in machine drawing, who need a little more explanation than the more proficient ones; and I hope it will prove of some use to rising young mechanics.

It should, indeed, prove useful to all, whether workers in wood or workers in iron, to study papers of this kind, for the sake of the expositiou of theory contained therein, which, when duly comprehended, cannot fail to be helpful in actual practical work.

## TOY BALLOONS: HOW TO MAKE THEM.

BY T. S.

PREPARATION OF MODEL—CUTTING GORES—JOINING GORES—WIRE HOOP AND LOOP—SUSPENSION OF SPONGE CHARGED WITH SPIRIT—STARTING BALLOON.

I HAVE had considerable experience in the construction of fire balloons, but none in gas balloons, but with the instructions in Vol. II., page 762, there should be no difficulty in making gas balloons also.

Obtain twelve sheets of common tissue-paper, any colour; but I find that the sizes differ, and allowance should be made for this. Cut a sheet of plain paper the same size as the tissue, and commence by drawing a pattern or model. Draw a circle, as shown in Fig. 1, 12 in. in diameter; divide it vertically by a straight line, and at the lower end set off 2 in. each side, and join by curved lines to your taste. Divide the semicircle on one side of the model into any number of equal parts, as shown in Fig. 1, and

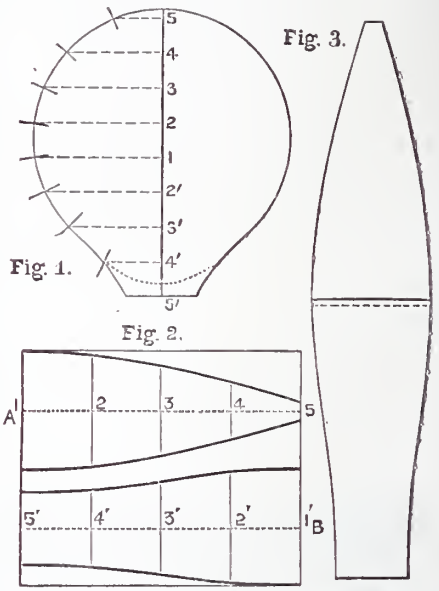

**Fig. 1.—Pattern or Model for Toy Balloon. Fig. 2.—Gore set out in Two Parts on Tissue Paper. Fig. 3.—Parts cut out and joined to form Gore.**

from each point of division draw horizontal lines or ordinates at right angles to the vertical line, and number them, as indicated in the diagram. Next take a sheet of plain paper, and draw a line 6 in. from each edge, shown in Fig. 2 by dotted lines, A, B. These will be the centre lines of each of twelve gores. Take the centre ordinate, No. 1, as an equator, and set the distance on each side of the dotted lines at A and B. Set off along A and B as many parts as there are ordinates, draw lines 1, 2, 3, etc., and set off the ordinates on each side as shown. Cut out at these points, and you will have a pattern gore in two pieces of the largest size that will cut out of a sheet of tissue paper, and will make a balloon 12 ft. round the equator, and about 4 ft. high. You will notice that the ordinates, 5 and 5′, should be set off on the edges of the paper, the larger one, 5′, being the mouth of the balloon, which should be about 16 in. diameter. The top, 5, is left, so as to make a hole in the finished balloon about 6 in. diameter, to be covered with a circular piece of paper when all the other joins are dry. Having cut out the pattern, lay it on the twelve sheets of paper, and carefully cut round through the lot with a strong sharp pair of

scissors. Some weights are to be placed on the paper to keep all in place while cutting, and the whole moved about so as to cut without any disturbing the paper.

To join the gores together, take them in pairs, and lay the upper one carefully smooth, and place the lower part on it, so that the under part projects ¼ in. beyond; then another upper part and another lower part, each ¼ in. lap, and so on, until all the twenty-four pieces are laid out. Be very careful that the centre lines are over each other, or the gore will not be straight. Now, after placing on some weights, paste gum or thin glue over all the ¼ in. laps, and at once turn over each on its proper part, and the twelve joints will be made. Dab down with a cloth to ensure a close joint, and before drying open out each, and let it dry open, hanging on a line. You will now have twelve well-shaped gores, as in Fig. 3, which, when dry, should be laid in pairs, and joined together as before, taking care what you do join. Having finished five joins on one side, turn over, and do six on the other. Open out as soon as possible, or the paste will make a double joint by soaking through the paper to the next sheet; and make the final joint in the same manner by folding back the inner sheets until the top and bottom sheets only are left. You will find some lead or other heavy weights very useful to keep all in place. Be careful to keep the equators opposite each other; never mind the top and bottom. When dry, open carefully out. Cut out a circular piece to close the top opening. Pass a circular flat tray or small work-table into the mouth of balloon (I have used a dinner plate), and after carefully spreading out, close the top opening.

Obtain some common iron wire, rather thicker than a common pin, measure the opening or mouth, and make a neat hoop same size, with neatly twisted join; pass it into the mouth, and turn up the edge over the wire ½ in.; paste, and dry. Take another piece of wire, about 1 in. or so longer than the diameter of mouth, form a loop in centre, and hook the looped wire on to the hoop at each side, of course selecting opposite gores to fix the hook to. This will carry the fire, which should be a piece of sponge of the size of an egg when dry. Lightly twist a piece of wire round it with a hook as close as possible, so that, when hooked into the loop across the mouth, it will hang close to it. To send the balloon up, select a situation against a building out of the wind. Avoid *trees*, *wood buildings*, and *thatched roofs*. Put your sponge to soak in some methylated spirit of wine. Have ready some torches made of loosely twisted newspaper. Get someone to hold out the balloon, and having lighted the torch, carefully pass it up into the balloon, which will soon expand and try to rise. Someone should now hook on the wet sponge, and with a little care the torch should be withdrawn and the sponge lighted at the same time. Do not be in too great a hurry to let go, but hold it by the edge of the mouth, and when it seems inclined to rise, let go with a twist, so that it spins as it rises, and does not swing about. I have successfully let off scores, no matter how the wind blew. Of course, you can have coloured gores, and can colour your fire to taste.

These balloons give great pleasure, and cost nothing but a few hours' work; but at the shops a balloon of the kind described above would cost from 3s. 6d. to 5s., which is a long price to pay for an article of this sort.

## APPLIANCES FOR WORK TO BE MADE BY THE WORKER.

BY B. A. BAXTER.

GUIDES FOR MITRE-BOX—GUIDES FOR GROOVING AND STEP LADDER MAKING—MITRES FOR NEWEL CAPS—CUTTING LENGTHS FOR BOXES—SAWING DOVETAILS—BENCH HOOK—STOPS ON SHOOTING-BOARD—"DONKEY'S EAR"—OCTAGON STRIPS—SASH BARS—WOODEN COGS.

RECENTLY I advised the amateur to imitate the professional in making appliances to aid him in his work, on the ground that it would improve his work and add to his resourcefulness. The workman who, above all else, seeks to do his work with the least trouble to himself; the manufacturer (who does not generally make with his *own* hands) who desires the greatest output; and the amateur, who requires every aid that he can obtain in order to surmount the difficulties of unaccustomed operations—all alike can make profitable use of any helps that are suggested or provided.

Only mechanical purists can object to these helps; and as such people are few, and probably will not read this little article, I shall ignore them, and proceed.

In order to preserve something like order, we will discuss appliances for sawing, planing, chiselling, and boring, in the order I have placed them.

Everyone knows the difficulty of sawing—that is, everyone who has tried to use a saw knows, first, that it is difficult to make the tool cut, and when that is accomplished, that it is not at all easy to cut *accurately*.

The most widely known appliance to assist in accurate sawing is, perhaps, the mitre-box (Fig. 1), used for cutting mouldings, picture framing, etc., to the proper angle. I shall not describe it, as a drawing has already appeared in WORK; but would only say that its usefulness can often be increased by making it longer, and having a stop fixed on it to gauge the length of the moulding to be cut; and also that square cuts, as well as at other angles than 45°, can be made with its assistance. If several pieces are to be cut to similar size, it is profitable to make a rough appliance of this kind.

Further, if a hexagon card-tray in fretwork is to be put together, it is less trouble to make a cut at the angle of 60°, and then fix a strip on the board (Fig. 2) corresponding to the elevation angle of the sides, than to find the angle and set bevels, and mark and cut in the most careful and scientific manner.

In grooving across thin boards for partitions, beginners often find a difficulty in sawing truly. If a strip of thin wood, having its edge straight and square, is laid upon the work exactly to the line, and the left hand placed firmly upon it, a great help is at once obtained in cutting for the grooves. The saw will work close to the strip, and no fear of the saw wandering from the line causes a nervous indecision in the worker. Immediately the saw has made for itself a path, the strip may be removed.

A similar assistance can be obtained in making step ladders, or anything in which a repetition of the same distance is required. (Fig. 3.) A piece of wood cut to the correct length and angle has on its edge a stop, whereby it may be held, always at the proper angle, on the material. It becomes then, in effect, a gauge, a bevel, and a set-square combined. (Fig. 4.)

In making such articles as seats for lecture-rooms, etc., gauges for the recesses, mortises, curves, and scribings can easily be cut in sheet zinc, and right and left ends can be marked with equal facility by simply turning the pattern. (Fig. 5.) This, of course, applies not only to sawing, but also to other operations.

There is also a contrivance for sawing mitres in newel caps, which I will try to explain. It is obvious, on consideration, that any straight line drawn from the circumference of a circle towards the centre must be either a radius or parallel to a radius of the circle; and if some contrivance can be made to ensure the right width and proper angle—especially keeping the opposite angles the same—we can make a useful help for cutting mitres to newel caps. (Fig. 6.)

If, therefore, a centre line is drawn on a piece of wood, upon which line the centre of the turned cap is applied and fixed, two saw cuts, equally distant and parallel to the centre line, will give guidance to the saw in cutting the V-cut for the insertion of the handrail.

A very simple help towards cutting off lengths for boxes, trays, or similar small work of which a number are required, consists merely of a piece of wood a trifle longer than the length of the pieces required, and on the under side fix a stop. Then, by placing the gauge on the work, neither square, rule, or pencil is required to cut off many pieces of uniform length. (Fig. 7.) This has been very useful to the writer of this in making partitions for what are termed pigeon-holes, and the plan is also capable of being used as an assistance in planing. (See also Fig. 8.)

For sawing dovetails so that they have the uniformity that adds so much to the appearance of the work, there is an easily-made appliance. All that is required is a small piece of wood rebated at the end, and the dovetail saw used to make a model dovetail in the reduced thickness, care being taken to preserve similar angles; or the dovetails may be uniform in size, but the pins will look misshapen. (Figs. 9, 10.)

For the circular saw many dodges are used, but they mostly resolve themselves into templates of various forms (Figs. 11, 12), and can be divided into appliances for cutting at various angles on plan, as picture-frames or elevation, as cutting strips of a wedge-shaped section, such as bottom sticks for roller blinds, and cutting off arrisses from pieces of square section, such as octagon blind-rollers. This last, however, needs a trough rather than a template, and will be mentioned among the appliances for planing which follow this (similar to Fig. 21). The applianee for cutting dovetails on a circular saw by the Britannia Company is a clever instance of the same simple expedient, which many have used in part, though not, perhaps, so fully. There is also a well-known contrivance called a bench hook. This, sketched in Fig. 13, is very useful in sawing small work, shoulders of tenons, etc. If made about 11 in. or 12 in. long, it may be used instead of a shooting-board; and for holding wood under the operation of chiselling it is of value. Its great use is, however, for cutting shoulders to tenons, forming an excellent stop, and greatly aiding the worker.

For planing, the great assistance of home-made contrivances is obvious in the number which exist, and which, perhaps, we may, as the result of this article, increase.

The ordinary shooting-board is exceedingly useful for planing edges of boards too thin or flexible to treat in the bench screw; but it is too well known to need a lengthy description. There are, however, additions to the ordinary shooting-board which will

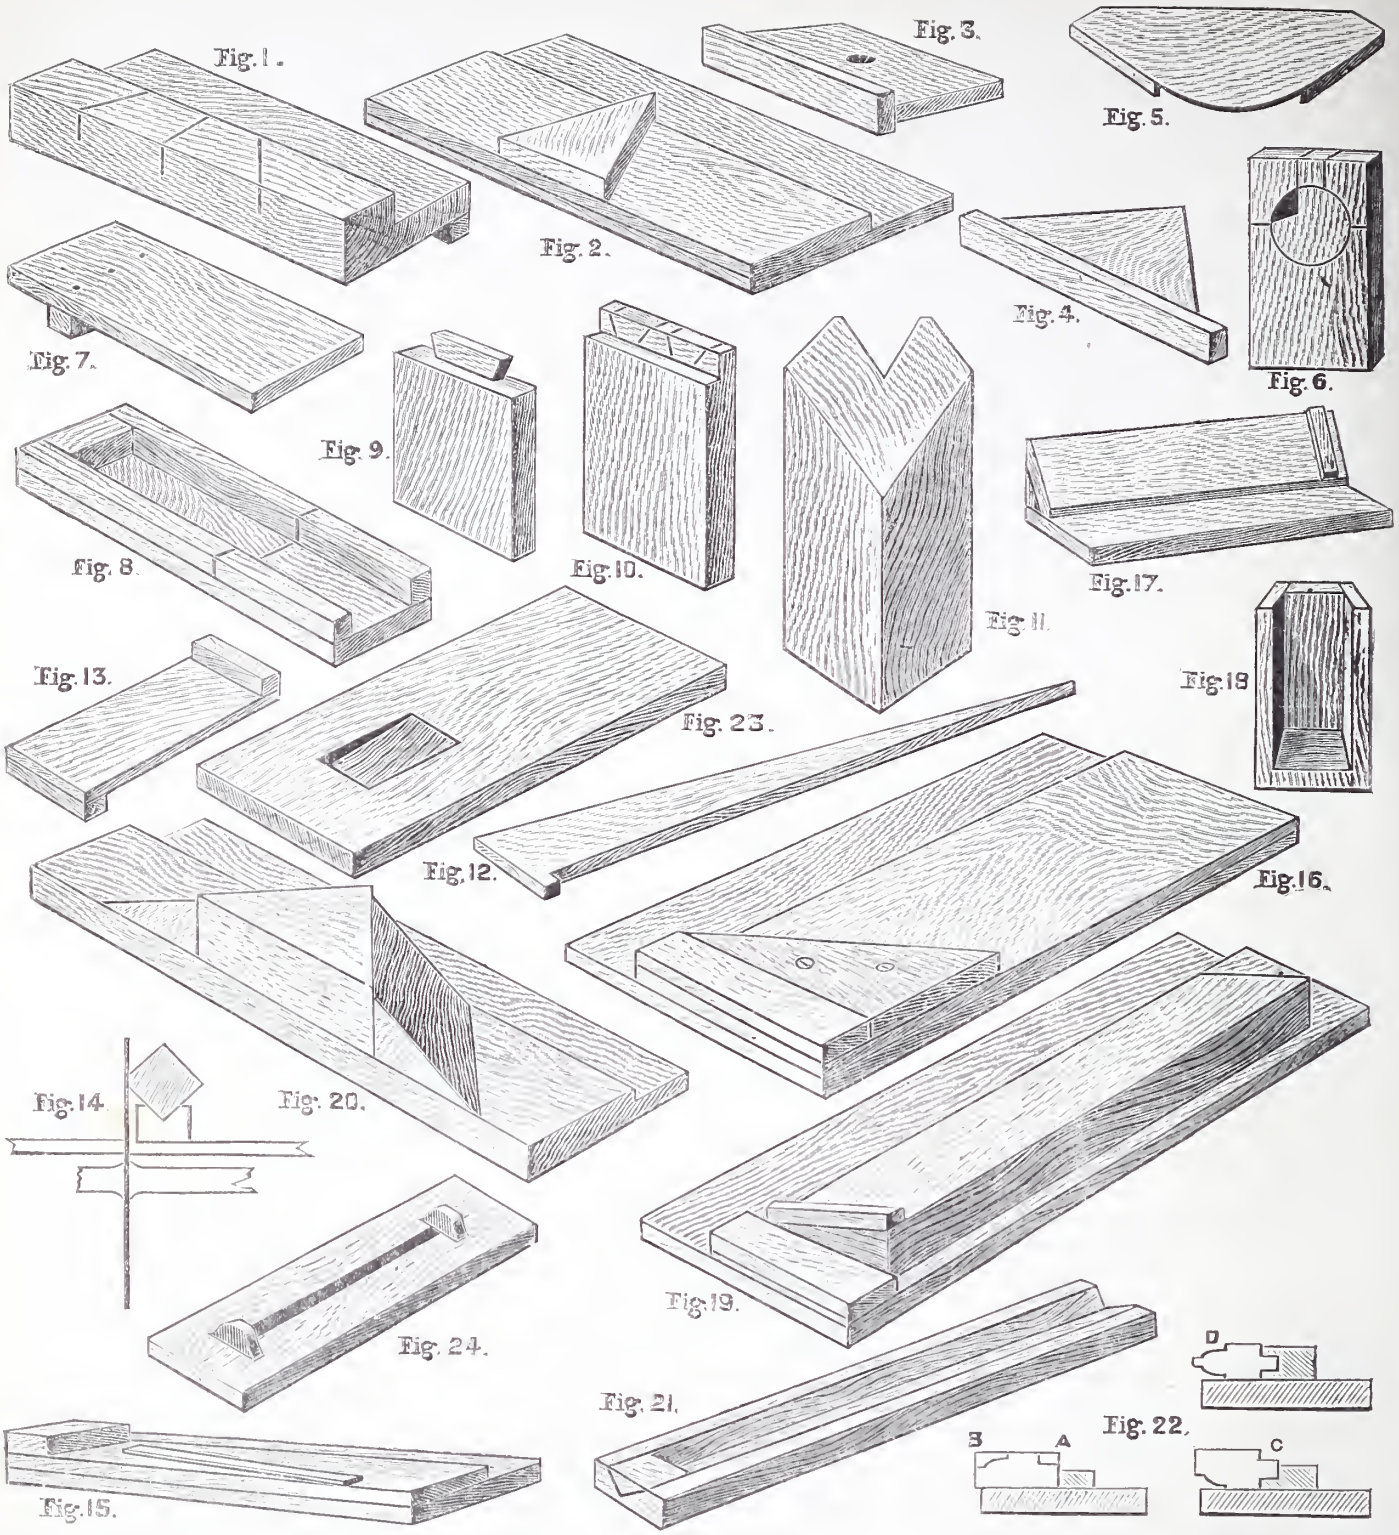

Fig. 1.—Mitre cut for sawing Mitres. Fig. 2.—Mitre for Hexagon. Fig. 3.—Gauge for Step Making. Fig. 4.—Pitch Board, also applicable to Circular Sawing. Fig. 5.—Gauge for Corners. Fig. 14.—Trough for Circular Sawing. Fig. 15.—Shooting-Board with Taper Attachment. Fig. 16.—Shooting-Board altered for Occasional Use. Fig. 17.—Mitre-Board for Partitions of Trays, etc., "Donkey's Ear." Fig. 18.—Upright Trough for planing to a Length, front removed. Fig. 19.—Shooting-Board with Movable Angle Strip for Pedestals. Fig. 20.—Mitre-Board with Angle Blocks. Fig. 21.—Trough for Rollers, suitable, with slight alterations, for Circular Sawing or Planing. Fig. 22.—Sticking-Board for Sash Bars with Strips: begin by making Rebate A, then Moulding B, then Rebate C, and finish with Moulding D. Fig. 23.—Board for Wedges. Fig. 24.—Template for Wheel Cogs.

add to its usefulness for special purposes. Of these, a temporary stop, fixed parallel to the edge traversed by the plane, is the simplest. This will be found of great assistance in planing a number of pieces of wood to uniform width. After the required number have been prepared, the stop can be removed from the board. Another addition, useful at times, resembles the parallel ruler, with this exception—that it is for securing a uniform taper to the pieces of wood in course of preparation. There is also the adjustable stop to make angles other than 90°, which ought to be mentioned. If the centre on which the stop turns is as near the corner of the stop as possible, the work will be facilitated, and the usefulness of the shooting-board be less hindered. A wing nut and bolt working in a slot would fix the whole to the desired angle; or a movable piece might be fixed on the shooting-board, as Fig. 19 suggests.

Leaving the shooting-board for mitres of picture-frames and cabinet-work out of the

question, as being universally known to the readers of WORK, there are modifications which may not be so familiar. There is the mitre-board, commonly called the "donkey's ear," which is used for mitred partitions and small mitred boxes (see Fig. 17); there is also the trough-like box which so materially helps plane makers to get bead and rebate planes so square at the ends and uniform in length; modifications of the shooting-board for making pedestals for statues or for loo tables, or such purposes as require angles other than right angles to be made with ease and uniformity. This, of course, may be only an attachment to the ordinary shooting-board. In a similar way, an addition to the ordinary mitre-board will enable the worker to mitre bevelled picture-frame linings, which would, to some pictures, form a pleasing change to the flat gilt mount so often seen.

Then for the purpose of making octagon strips from square lengths of wood, preparatory sometimes to rounding them, a help may be afforded by an appliance made by cutting down a square strip diagonally, and fixing the two strips made thereby on a flat piece of wood. Any suitable stop will then hold a strip in the right position for planing off the angles. (See Fig. 21.)

The preparation of sash bars (Fig. 22) almost necessitates some appliance to hold the piece of wood while being converted into a sash bar.

The rebates should first be made, to do which with ease, a board, having at a convenient distance a strip to resist the pressure of the sash fillister, a few steel points driven into the board, leaving about ⅛ in. standing out and pointed, so placed that they will stick into the bar where the other rebate will remove the marks, will do for the first rebate, A. For the rebate on the other side, it needs a piece of wood, as in C, equal in thickness to that which has been planed away, to support the bar while the second rebate is being made; and for moulding the bar, a piece of wood equal in thickness to the bar, and having a groove into which the rebated bar can now fit, as in D, will be found most convenient. It will seem simple to some to point out that anyone who wants to make some wedges of uniform size can find much assistance by making a suitable mortise in a piece of hard wood, deepening one end as required, and plane the wedges while they rest in such a receptacle, as in Fig. 23.

Pattern-makers can shape wooden cogs to affix to their wheel patterns by planing to the outline of a template at each end of the strip. (Fig. 24.) The same agreement of outline in brackets or other shaped work can be obtained by sawing and shaping several together on the same principle.

## KNOTTING, SPLICING, AND WORKING CORDAGE.

BY LANCELOT L. HASLOPE.

### EYE KNOTS.

RUNNING KNOT OR SLIP KNOT—FISHERMAN'S EYE—OPENHAND EYE—FLEMISH EYE—CRABBER'S EYE—BOWLINE KNOT—RUNNING BOWLINE ON A BIGHT—HANGMAN'S KNOT—RUNNING KNOT WITH TWO ENDS—RUNNING KNOT WITH TWO ENDS FASTENED.

ONE of the simplest of these is shown in Fig. 15. It is the "Running" or "Slip Knot." A bight is first formed, and an overhand knot made with the ends round the standing part. The standing part may be drawn through the knot, and the eye made to any size required. There is less chance of the knot coming undone if an overhand knot is made on the end A. This is the knot with which a sailor ties his neck-handkerchief, and it is therefore sometimes called a sailor's knot.

Fig. 16 is the "Fisherman's Eye Knot." A bight is first made of sufficient length, and an overhand knot formed with the standing part round the other strand; the end is now passed round the standing part, and knotted as before. We now have a running knot A, with a check knot B, which, when hauled upon, jam tight against one another, and hold securely. This is one of the best knots I know of for making an eye in fishing, as the strain is equally divided between the two knots. Fig. 17 shows a very common way of making an eye on the end of a piece of cord—indeed, you will often find those who know no other mode of doing so. It is practically the same knot as Fig. 8, only, instead of being made with two ropes, one only is used. The end is brought back along the rope to form the eye, and an overhand knot made with the two parts. This knot, from being so easily made, is often used, but as it lacks strength, like the openhand knot (Fig. 8), it is not advisable to use it where it is required to bear much strain. My readers will by this time doubtless have noticed how very often openhand knots come into requisition as component parts of other knots.

Fig. 18 is an eye made with a "Flemish" knot. It is worked just the same as a single Flemish knot, the only difference being that two parts are used instead of one. It is stronger, but clumsier, than the one just described. It is not very often used.

The "Crabber's Knot" (Fig. 19) is a curious and not very well-known knot. I learnt it one day coming home from fishing in a friend's yacht. His captain was an old crabber, and we had been discussing the best form of eye knot for fishing gear, when he recommended me this one as being very secure, and less likely to part at the knot when a strain was put on it, than any knot he knew. To make it, bring the end back to form a loop, taking it first under and then over the standing part, up through the main loop, over the standing part again, and up through its own bight. Before the turns are hauled into their places, the knot will slip on the part A, as in an ordinary slip knot; but if the part B is hauled upon, the strand A, which passes through the centre of the knot, rises, and the coil which goes round it jams, making the knot secure: so that it may be used as a running knot or otherwise, as desired. This is also called a running knot with crossed ends.

Fig. 20—the "Bowline Knot"—is one of the most useful knots we have. It is impossible for it to slip, and it is therefore always used for a man to sit in when he is slung, for the purpose of doing some particular piece of work. The end is first laid back over the standing part, so as to form a

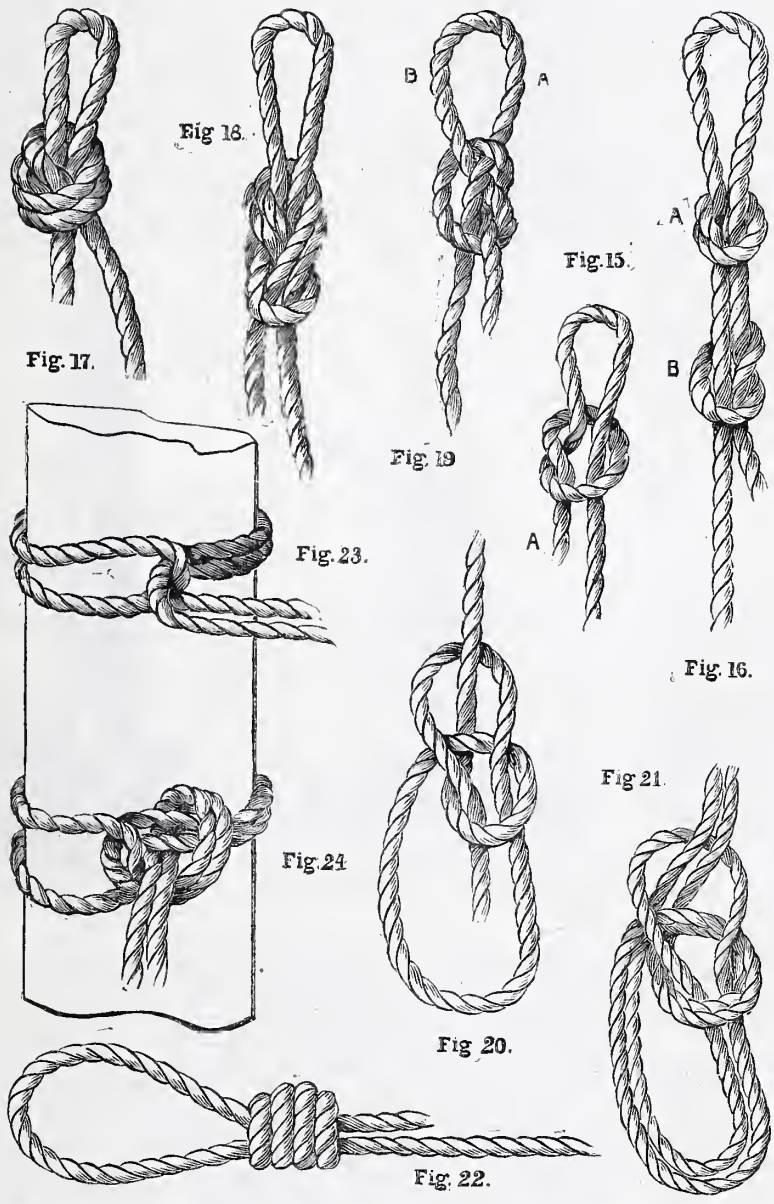

**Fig. 15.—Running Knot. Fig. 16.—Fisherman's Eye. Fig. 17.—Openhand Eye. Fig. 18.—Flemish Eye. Fig. 19.—Crabber's Eye. Fig. 20.—Bowline. Fig. 21.—Running Bowline on Bight. Fig. 22.—Hangman's Knot. Fig. 23.—Running Knot with Two Ends. Fig. 24.—Ditto fastened.**

loop; the end is then passed up through the loop, round the back of the standing part, and down through the loop again. Hauling on the end and the standing part makes the knot taut.

Fig. 21 is a modification of this knot, called a "Bowline on a Bight." The loop is made as in the previous knot, only with the two parts of a doubled rope; the bight is then passed up through the loop, opened, and turned backwards over the rest of the knot, when it appears as in the figure. To untie it, draw the bight of the rope up until it is slack enough, and bring the whole of the other parts of the knot up through it, when it will readily come adrift. If the standing parts of the rope are held fast, it puzzles the uninitiated to undo it. I remember hearing of a mischievous person who used to amuse himself by going round to the country inns, and making this knot on the bridles of any farmers' horses he could find tied up outside; the result being that the old farmer, whose wits probably were not sharpened by his recent potations, had generally to cut the reins before he could get them over his horse's head. A "Running Bowline" has the knot made on the end after it has been passed round the standing part, thus forming a loop through which the main rope will run. Two ropes may be joined together by making a bowline in the end of one of them, and putting the end of the other through the bight, and forming with it another bowline on its own part. This is often used to join hawsers together.

Fig. 22 is the "Hangman's Knot." A bight is first formed in a rope, which is held in the left hand; the end is then coiled several times backwards—that is, from right to left round the standing part—and then passed forwards through the coils. It is made more easily if, in the case of small stuff, the first finger of the left hand be laid along the standing part, and the coils made round them both. This keeps the coils open, so that the end passes through them readily. In the case of larger cordage, a piece of stick may be used. The advantages of this knot for its particular purpose are that when well greased it runs very readily, and that, from its large size, it presses on the veins of the neck, and thus extinguishes life more rapidly than a smaller knot would do. I believe our modern executioners instead of this knot use a thimble—that is, a grooved ring of metal spliced into the end of a rope, and the main part passed through it to form the fatal noose.

Fig. 23 shows a method of making a rope fast to a post or pillar. The rope is doubled and passed round the post, and the ends put through the loop. If it is required to make this fastening secure, the ends may be passed round the standing part and through the bight thus formed, as in Fig. 24; or, instead of passing the cords through the bight, a loop may be formed by doubling the ends, and this loop put through the bight, thus forming a slippery hitch. This knot has the advantage of being more readily undone than the other one, as we have only to pull at the ends, and the rope is released at once. We may also secure the ends by making a Flemish knot on them, instead of an overhand knot.

This brings us to an end of the consideration of the various knots that are in use, classified as simple knots, knots for joining ropes, and eye knots. In my next paper I shall endeavour, by means of description and illustration, to make the reader acquainted with the modes of making hitches and bends.

## OUR GUIDE TO GOOD THINGS.

*** *Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of* WORK *for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of* WORK *without charge, the notices given partake in no way of the nature of advertisements.*

### 17.—Pope's Improved Carriage Jack.

In Fig. 1 an illustration is given of the "Improved Carriage Jack" recently introduced by Messrs. W. Pope & Co., Engineers, etc., Barley Fields Iron Works, St. Philip's, Bristol, and manufactured by them in two sizes, sold respectively at 12s. 6d. and 15s. 6d. each, the smaller size being sufficiently high for all ordinary carts and carriages, from very low phaetons to the ordinary dog-cart, and the larger size intended to meet the requirements of axles of very high carriages and dog-carts and breaks that are equally high. The working is very simple. The jack is merely placed under the axle, and the handle A is lowered to the position A′, as shown by the dotted lines; the plunger B then rises to the position B′, and handle and plunger remain locked in position. The jack may be altered for high or low axles by placing the link or bridle C under one of the notches or teeth, shown in the part D to the left of the illustration. Both sizes will lift carriages up to a weight of about 30 cwt. The jack does not depend on any frictional grip, and may therefore be painted all over to prevent rust and corrosion. It is made entirely of good malleable iron, and consequently is not liable to get broken through a fall or any other accident. The head is capped with wood to prevent damage to the paint of carriage axles, etc. The advantages of the Improved Carriage Jack are automatic locking when up, extreme lightness and strength, cheapness, and capability of being carried conveniently in the boot of a carriage for immediate use in case of need or accident.

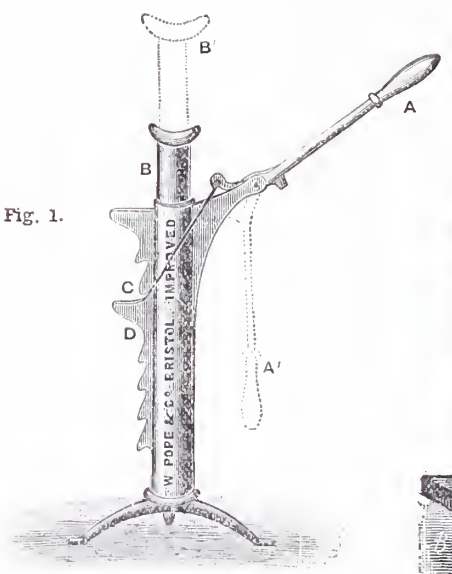

Fig. 1.

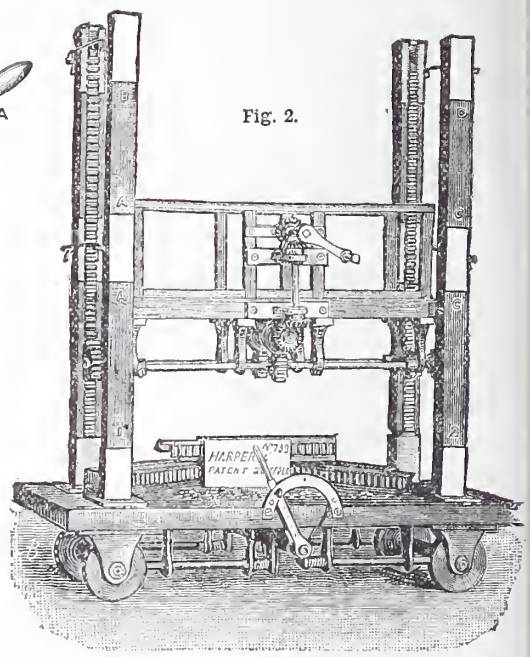

Fig. 2.

Fig. 1.—Pope's Improved Carriage Jack.
Fig. 2.—Harper's Patent Scaffold and Hoist.

### 18.—Harper's Patent Scaffold and Hoist.

The Patent Scaffold and Hoist, invented and made to suit any requirement by the patentee, Mr. J. Harper, 129, King's Road, Camden Town, London, N.W., can be used for every description of building and decorative work, internal or external, as well as for building purposes, instead of the ordinary cumbersome and expensive fixed scaffolding. All inquiries as to price should be sent to Mr. Harper and not to me, and as I have not seen the scaffold and hoist at work, I must content myself with giving to a certain extent Mr. Harper's description of it. I may, however, add that, from what I can gather from the description and illustration supplied in Fig. 2, there is no doubt whatever in my own mind as to its utility for the purposes for which it has been specially designed. The scaffold, which is portable and self-contained, comprises an upright framing constructed in sections, so that it may be readily raised to the height required by the work, and a platform fitted to move up and down in the framing, with gear worked from the platform itself, whereby it may be raised to, and maintained at, the elevation required. The scaffold is mounted on wheels so that it may be easily moved from place to place. The framing comprises a bottom fixed platform mounted on wheels, and four corner posts or columns fixed in shoes and constructed in sections bolted together, the four columns being braced together by diagonal tye rods furnished with screw couplings. On one of the inner faces of each of the four posts is a rack, and with these racks are gear-pinions on a pair of shafts mounted beneath the rising platform, these shafts being geared with a worm gear common to both and operated through bevel gear from a winch handle mounted at convenient height above the platform. On the other inner face of each corner post is a guide of dovetail or T-section, with which engages a shoe on the end of the platform whereby all outward defection of the corner post is prevented and the wheels are held in gear with the racks. The travelling wheels on which the apparatus is mounted have peripheral holes in which engage locking bolts mounted beneath the base platform and coupled to a common lock shaft operated by a lever for the purpose of holding the scaffold stationary when in use. The whole apparatus can be put up or taken to pieces in a short space of time by any ordinary workman, who cannot make any mistake in the work, every section being marked as shown in Fig. 2. The advantages possessed by the Patent Scaffold and Hoist over the old system of scaffolding are numerous. Firstly, no ropes, poles, putlogs, ladders, or scaffolders are required. Secondly, it is far more useful for interior work than the old scaffolding, which cannot be removed until the work is completed, a matter attended with much inconvenience in large places of business in which cleansing, repairs, decoration, electric lighting, etc., are chiefly done in the night, and the patent scaffold can be

uickly put up at nightfall and as quickly removed a the morning. Thirdly, the workmen employed an put the material required into the cradle nd wind themselves up to the height required vhen at work, thereby saving time and labour. Fourthly, it is perfectly safe, and cannot by any neans work down unless worked by the men in he cradle; further, being self-eontained it can e stopped at any point, and affords sure safe-guards against accidents that often arise from the se of temporary scaffolding composed of planks, adders, etc. Lastly, for electric lighting it is pecially valuable, as the wire and wood casing an be conveyed to the height at which they are o be fixed, carrying the wire-runner and car-enter so that they can complete their work as hey run along. THE EDITOR.

## SHOP:

### A CORNER FOR THOSE WHO WANT TO TALK IT.

*** In consequence of the great pressure upon the "Shop" columns of* WORK, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* WORK *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### I.—LETTER FROM A CORRESPONDENT.

**Saw Buckling.**—W. H. R. (*London, N.W.*) writes:—"Having seen in No. 106, Vol. III. of WORK, a method of trueing buckled circular saw, I send you another method, often used in saw mills. When the saw begins to run wild, take the piece of wood you were sawing off the bench, and let the saw run; and while it is warm, get a mug of cold water and let it run on the saw, and it will very soon run true again."

### II.—QUESTIONS ANSWERED BY EDITOR AND STAFF.

**WORK Advertising and Addresses.**—We cannot give our contributors' addresses, but will attend to any stamped, directed letter. The rates for advertisements in WORK have been printed in every issue since No. 1 of the Magazine.

**Model Electric Lights.**—W.E.B.(*Birmingham*).—The articles on "Model Electric Lights" were published in WORK, No. 76, August 30; No. 82, October 11; No. 89, November 29; No. 92, December 20, 1890; No. 94, January 3; No. 97, January 24; No. 99, February 7; No. 101, February 21; and No. 104, March 14, 1891: nine numbers in all, forming part of Vol. II. All back numbers are in print.—G. E. B.

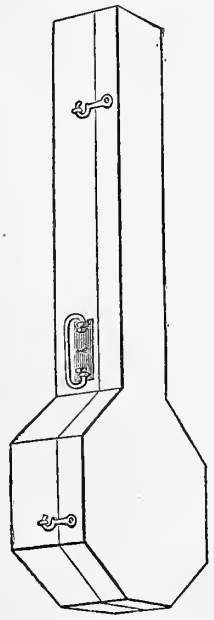
**Battery Zincs.**—SELF HELPER.—Battery zincs always work better when amalgamated, but it is not absolutely necessary to have them amalgamated for use in the Bennett caustic potash cell, since there is no waste of zinc when the circuit is open. Dilute acid cannot be employed in this cell, as the acid would dissolve the iron borings and the tinned iron sides of the cell.—G. E. B.

**Glass Working.**—SELF HELPER.—I do not know of a book at the price of 3s. 6d. There are two chapters on the manipulation of glass for laboratory purposes in "Practical Chemistry," Vol. I., by Harcourt and Modan; price 7s. 6d. The lessons are illustrated with sketches of the apparatus, and method of making them.—G. E. B.

**Cost of Electric Light.**—A. T. (*Hampton Wick*).—It is not advisable to have an electric light installation of only one 25 c.p. lamp, and one dynamo to light it, as the arrangement would involve a waste of power and material all around. If you must have a light of 25 c.p., get five 5 c.p. lamps, or two 10 c.p. and one 5 c.p. lamps, and divide the current between them. It would be even better to get either three 10 c.p. lamps or four 8 c.p. lamps. The lamps will cost you, at retail price, 5s. each, and holders for each from 1s. to 2s., according to quality. The dynamo will cost from £4 to £5 if bought new and complete. If you care to make the dynamo yourself, you will save half the cost, as the castings can be had in the rough for 16s., and the wire will cost about 2s. per lb. Switch, cut-outs, and leads or line wires will cost from 10s. to 15s. more, so that the whole installation will cost from £6 to £7, apart from cost of engine. I do not see why you must have a set of accumulators. These will only increase the cost, as each cell will involve an additional outlay of from 15s. to £1.—G. E. B.

**Fretwork Cornice.**—H. J. (*Kidderminster*).—It is not at all necessary that your fretwork cornice should be backed up with anything, though, of course, you may finish it by doing so if you wish. If you want a transparent, or rather a translucent, material, you cannot do better than use sarsanet, which may be the stuff you describe as being something like satin and unsuitable, because it is not transparent enough. The other material about which you inquire is gelatine in the form of thin sheets. It is transparent, but quite useless for the purpose, and no better than thin oiled tissue-paper would be. If you want to drape or, as you say, hang something below the wood to give a finish, I cannot suggest anything better than festoons of velvet or other suitable stuff, of which you will be able to get a large choice at any good house-furnisher's in your town. Loop the festoons with fancy cord, and trim edges with a ball fringe. Unless you have had practical experience in upholstery draping, you are not likely to make a success with the work, which requires not only skill but considerable taste, if the materials are to be used to advantage.—D. A.

**Banjo Case.**—LIVERPOOL.—You must make your case as light as possible if you make it of wood. If your wood is very thick, and you have to carry the banjo and case any distance, you will find that it will begin to weigh rather heavy before you get to your destination. The lightest cases are those made of cardboard and covered with American cloth, which answer very well for ordinary wear. You could rebate the sides of case to receive top and bottom, which could be glued and bradded (or sprigged) in. You can get the size from your banjo and make to fit it. Make the sides in one piece, and after the top and bottom are fixed, cut all round with saw, say 1 in. from top. Having done so, you will have your lid ready made, and, of course, the exact size and shape of the body of case. You could cut out the bottom to size, and then fit your sides round it, mitreing them together, and screwing or bradding, and not forgetting the glue. You could butt the ends of each section together, but it would not be such a good job as mitreing them. Line the inside with baize or plush, and paint or stain the outside to your own fancy. Put the hinges on extreme ends of case: if you do not attend to this you will find your case will not open and shut properly. You will see where to put them if you lay the lid on case and then lift it (the lid) up as if you were opening the case. You will see the shape by referring to illustration.—J. G. W.



Banjo Case.

**American Clock.**—P. W. W. (*North Shields*).—Neither from your sketch nor letter can I make out the arrangement of wires. I think that the centre wire is used merely to let off striking by a piece of wire hanging from it, in the event of running down, to obviate turning the hands; and as you say the clockmakers there do not understand it, having the whole affair before them, I feel more at a loss with only two wires to look at.—A. B. C.

**Inlaid Tops, etc.**—A. J. G.—If you want a quantity of these, any marquetry cutter will do them for you. Probably the most likely place to meet with them in London (you do not give your place of residence) is at D. Witt & Palmer's, Drummond Street, N.W.; or you might try some of the fancy veneer dealers in and about Curtain Road. There is a book called the "Practical Cabinet Maker," which might help you; though, unless you are what its name indicates, it is not likely to be of much use to you. You will find more valuable information in the volumes of WORK already issued in all that pertains to cabinet making than in any work I know of.—D. A.

**Varnish.**—J. S. (*Govan*).—The shellac spirit varnish to which you refer is, in reality, French polish. It will dry hard, with a good and lasting gloss, but is generally, indeed I may say invariably, applied with a rubber, and not with a brush. I know of no way in which it can be made transparent or limpid, like water, when in bulk. When applied to work, the film is so thin that it is transparent. The proportions required to make half a gallon, or any other quantity, must depend on what thickness you want it to be. Good ordinary French polish may be made by dissolving about 1½ lbs. shellac in half a gallon of methylated spirit; if you want it thicker, add shellac to suit yourself, or add resin instead. It is a pity you did not state what purpose you want to use the varnish for, as I might then have advised you something more suitable. In any case, console yourself with the reflection that varnish of most kinds can be bought more cheaply and of better quality than it can be made by amateurs. As you are so near Glasgow, you will be able to get the kind best adapted to your purpose, whatever it may be, without difficulty.—D. D.

**Weight of Cordage.**—R. J. S. (*Wolverhampton*).—The method of finding the weight of rope given by me on page 6, column 3, of WORK, No. 135, Vol. III., is from a book published by Routledge & Co. It is there stated to be "a good formula by Robison." Of course I had no means of testing the accuracy of it; but as apparently a good authority was given for it, I considered I was justified in adopting it. Your correspondent does not say absolutely that this formula is *wrong*, but merely that another authority—which, he states, is generally accepted by the trade as correct—gives a different result for the size of rope in question. My only connection with cordage is from having used and worked it for a full half century; and I must, therefore, admit my ignorance of the matter from a "trade" point of view, and, consequently, that I have never seen "Rabson's Tables." As the matter stands, it seems to me a case of Rabson *v.* Robison; and, as I take it, neither your correspondent nor myself is in a position to say *positively* which is in the right.—L. L. H.

**Piano Panel.**—INQUIRER.—Those most likely to have what you want are J. H. Skinner & Co., East Dereham, and Harger Bros., Settle. You might also write to Zilles. If you cannot meet with what you want, you may be able to adapt some of the published designs. There will be no difficulty in getting the wood you want, either in your own town or in Shrewsbury; but if you cannot meet with any, you can get it from the dealers above named, or from Busschott's, Park Lane, Liverpool, where I saw some very fine stuff lately. I am assuming you want plain or American walnut. If you want the Italian or burr walnut, you must get it in veneers, and either lay or have it laid for you.—D. A.

**Polishing Marble.**—W. B. (*Camberwell*).—Grind down first with coarse sand and water, then with finer, and finish off with putty-powder on felt mounted on a thick board. See details on p. 742, No. 98, Vol. II. of WORK.—D. A.

**Box Battery.**—J. H. (*Leicester*).—I suspect the cause of failure in your box battery to be due to corrosion of the connections by acid fumes arising from the cells. There may be an imperfect contact of carbon plates and the lead ring in which they were cast. Try the battery with a new solution. If this fails to light the lamp, you may determine on the fault being in the connections. If the battery lights the lamp when charged with the new solution, then the old solution was at fault. You adopted the right proportions—namely, 3 oz. of chromic acid and 3 oz. of sulphuric acid in each pint of water. The cost is rather high, 3d. per pint being quite enough. Good commercial acid is quite good enough. Let the solution cool before placing it in the cells, and see that the zinc plates are well amalgamated. The lead collars and the tops of the carbons should be painted with Brunswick black to keep the acids from creeping up and corroding the connections.—G. E. B.

**Coupling Battery Cells in Parallel.**—DENNY.—The resistance of a circuit is not increased by coupling up battery cells in parallel. On the contrary, each cell added to the circuit adds its own current to the general volume, without adding extra resistance to the circuit. Suppose we wish to convey water from one cistern to another, and put in two 1 in. pipes between the two cisterns in parallel. These will convey a certain quantity of water. We now put in an additional ½ in. pipe parallel to the two others. Although this in itself offers a higher resistance to the water than the 1 in. pipes, it does not in any way affect the resistance of the other pipes. It is much the same with cells. The partly exhausted Leclanché cell will not increase the resistance of the circuit when connected in parallel.—G. E. B.

**Cabinet.**—T. L. (*Balham*).—In due time there will appear a paper on how to make a canted-sides cabinet.—J. S.

**Banjo Rim.**—J. H. (*Everton*).—You ask for the best way to make a banjo rim, but you do not say if it is to be wood or metal. Supposing you wish to bend a piece of wood for a hoop, you must make a mould to size of diameter of hoop—an iron ring would be the best; or if you could find a pulley about the right size, you could bend it round the outside of that, using eight cramps to keep it to shape of pulley until you get it bent round in a circle, then drive in about three wire brads to keep it in shape. Failing the iron ring or pulley, you could cut a mould out of a piece of hard wood, turning it up to size or cutting it out with a band saw, boring holes round it or cutting out inside to allow the cramps to fix on. Prepare your wood, making it 2½ in. deep and ⅜ in. thick, cutting it to length according to the size you want the hoop, allowing for the ends to lap over each other about 3 in.; taper each end for splicing before you bend it; then steam or boil it well, and bend round the mould, using the cramps, and not forgetting to drive three or four wire brads into the ends lapping over one another, to keep it in shape when taken from the mould. The longer you can let it stand to dry, the better. Then take out the brads. See that the ends lapping over each other fit. Tooth them—you could do this by holding a tenon saw crossways on hoop, and drawing along with a

scraping motion, failing a proper tool—glue together, using hand-screws; then when glue is set, dress up the joint with spokeshave, which will make the hoop round enough for all practical purposes. Round the edge that the vellum stretches over carefully, so that there is no danger of wood cutting the vellum; then fit the band for pulling the vellum tight. The best bands are fitted to the hoops, and ends brazed together, and then are mounted in the lathe and have a recess or rebate turned in them; the object of the recess being to keep the nose of the bracket wires from cutting the vellum, which they would most certainly do if you used only a thin piece of brass for the band. Instead of making a recess in the band, get a piece of brass ⅛ in. wide and ⅛ in. thick, and bend it round to size of hoop: braze the ends together or halve and rivet them. Mark off and drill holes for brackets; fix ditto (using not less than twenty or twenty-four for an 11 in. or 12 in. hoop); put the band on hoop, and mark the exact place of each bracket on the band; then fill notches in band deep enough to sink the bracket wires into, and so prevent them from cutting the vellum. You will then have a band good enough for anything. If the information you require is how to make a metal hoop, I must refer you to what I have written in the back numbers. I have given the numbers in answer to a query by another correspondent, which has not appeared up to the time of writing this, but which, no doubt, you will have seen before this is printed. I forgot to say that you could use two drain pipes, one stuck on top of the other, the joint made good with clay, filling with water, and lighting a fire round bottom of pipe, to steam and bend your wood. This method was suggested by a correspondent in a contemporary of "ours."—J. G. W.

**Banjo Making.**—F. W. (*Southsea*).—I should advise you to use pegs in place of machine if you intend to put gut strings on your banjo. A machine is simply a nuisance for using with gut strings, but is very necessary for wire strings. For instance, a zither banjo having all wire strings would require a machine—wire strings being difficult to tune with pegs. For the latter part of your query see advertising columns. See also WORK, No. 88, Vol. II. —J. G. W.

**Pine Harp.**—S. E. (*Chelmsford*).—I can give no reliable information on this instrument. It is probably one of the home-made tribe used by "variety artists," and as a musical instrument has not come under my notice.—R. F.

**Clock Cleaning.**—VULCAN No. 2.—I am not sure I quite understand your difficulty about the striking, but in most French clocks the fly is pivoted, on the pinion end, in a movable eccentric bush. By turning this to throw the fly-pinion deeper in the warning-wheel, it will strike slower. To make it go faster, turn it shallower. As regards the German clocks, if not provided with a movable bush, see that the fly is tight on the pinion, as sometimes the pinion rushes round without the fly or fan piece; and sometimes the pinions are worn and the holes are wide. If so, put new holes to the fly and new wires to the pinion of the fly, and I think you will have no further difficulty. I can recommend Britten's "Watch and Clock Makers' Handbook."—A. B. C.

**WORK Paging.**—The numbering of the Advertisement pages of WORK must continue. Thank you, however, for your suggestion.

**Pattern-Making Book.**—G. S. (*Headington*).—There is a book on "Pattern Making" published by Crosby Lockwood, 7, Stationers' Hall Court, at 7s. 6d. That is a practical work, and might suit you.—J.

**Cleaning Tools.**—H. W. (*Rochester*).—Rub any rust off with emery-cloth; and if the tools are in occasional use, rub with sweet oil. If they are to be put away for a considerable time, rub with mutton fat.—J.

**Testing Paint.**—A. F. (*St. Leonards*).—The most practical way of testing oxide paint would be an examination as to colour and degree of fineness in grinding. I assume you mean the oxide in paste form, and not diluted with oils for use; as, in the latter case, the oil would be a factor of importance—whether good "honest linseed" or "fishy" oil, in the twofold sense. Oxide is so cheap, there is no need to adulterate it, although there are several qualities of colour (brightness) and fineness. In actual use the oil is more the preservative than the oxide, which is rather a *cheap* body pigment with affinity to ironwork.—F. P.

**Graining and Painted Inlays.** — THE SCRATCHER writes:—"In WORK, No. 100, is a paper on Graining. I beg to differ with the writer with respect to treatment of panels Nos. 7 and 8. I agree with him so far as he treats the maple up to the varnishing; but I fail to see how he can get a good imitation of walnut by the way he suggests, seeing that he has not laid down a proper ground for walnut: and it is impossible to get a good imitation on maple. In my opinion, the manner given in this paper, 'How to Treat Panels,' Nos. 7 and 8, are somewhat roundabout, and I am afraid the finish would not be as satisfactory in practice as it is set forth in theory. If I may suggest a method, it is this: maple your panel as stated, then pounce on the design, and fill in the design with a walnut *ground in oil;* let same dry, then grain over with walnut in distemper, as stated in your paper. Then take a fine pencil and go over the design with a little mixed turpentine and varnish; you will find very little difficulty in following the design you wish to fasten with this mixture of turps and varnish, as the walnut ground, being so much darker than the maple, will be perceptible through the graining. When dry, rub over with sponge and warm water, which will remove all the graining colour not required, and leave your design intact. To work your ebony ornaments, mix some lamp-black in beer, and coat over the panel where the ebony is required; then pounce the design on this black, and with the mixture of turps and varnish trace over the design to fasten: when dry, take sponge and water, and treat the same as the walnut. When these directions have been followed, go over the whole of the panel with a light-coloured varnish, so as not to darken the maple. In the article on Graining, I suppose the writer took it for granted that the amateur was capable of laying in and finishing a maple panel, as he fails to explain to him how to do either. When I took up my paper and saw the article above referred to, I thought that it would contain some useful information respecting graining, but found it simply treated with the decorative art proper, without giving a single method of how to imitate grained wood. I would like to point out that the decorator and the grainer are two distinct workmen."—[Notwithstanding the main portion of your criticism is based upon its writer's own misconceptions, it is but fair that your well-intentioned letter should be fully answered, if only from the fact that it is the only occasion of any directions contained in the "Art of Graining" having been questioned as to their practical reliability. Taking your points *seriatim*, which refer to the instructions on pages 772 and 774 (No. 100, Vol. II.), you "fail to see how he can get a good imitation of walnut by the way he suggests, seeing that he has not laid down a proper ground for walnut, and it is impossible to get a good imitation on maple." In answer to this, I would ask you—presuming you are a practical grainer—how much walnut figure it would be worth one's while to imitate on the dark ornament of panel No. 7? Scarcely any, I say, and therefore the main point of inlay work—real or imitation—is worked on the principal of contrast, of colour, or of shade. But here your practical knowledge of painted inlays must be very limited, since you say that to get a good imitation, the fine ornament of panel 7 must "be grounded for walnut." It is a matter of mere general comprehension that such an opaque coating of body-paint cannot be pencilled on or stencilled without showing a perceptible thickness, and which, when varnished, would have as much claim to imitation carving—wood in relief—as it would have to being inlaid—"let into." I say it most emphatically, that for purposes of ornamental inlaying, walnut, rosewood, etc., are best worked upon the "ground" of the lightest wood, and that in no case can good work be done by grounding each wood in its own special colour. I assume that "inlay imitation" is interpreted by my readers in accordance with the appearance of real marquetry, and not simply as one kind of wood colour painted partly over the surface of another. Further on you question the value of the "stopping-out" process as "being roundabout." Compared to pencilling in the ground for the ornament of panel 7, as you advise, stopping-out is simplicity itself. That it appears odd to you, and many grainers who may never have attempted anything out of the ordinary groove of graining, is very probable; but it declares at once that your criticism is based solely upon a limited practice and effort. The concluding article in No. 103 doubtless made things plainer to you, but it may be interesting to mention that one variation of the principle of "stopping-out," as applied to *stained imitation inlays*, was patented by a prominent metropolitan decorative artist, Mr. Andrew F. Brophy, about twenty years ago, examples of which work were shown by the eminent London firm, Messrs. Trollope, in the 1871 Exhibition. Further on, your ideas as to ebony, or black stencilling, on maple are scarcely more than items of very ordinary knowledge, to which a plain stencil of gold size and ivory-black (ground in turps) would be superior. Finally, you say that the writer took it for granted that the reader knew all about grounds and graining all varieties of wood, as I "fail to explain how to do either," and that you would like to inform me "that the decorator and grainer are two distinct workmen." I hope by the time this is published you will have gathered that the two inlay papers were the last of a *series of fifteen*, dealing on each and every practical aspect and process of imitating woods, preparation, grounds, graining colours, and manipulative treatment. As to the "distinct workman," such is, in many instances, the case, *unfortunately* for decorative art in general and the ordinary grainer in particular. Had the grainers of "the old school" possessed a better understanding of how far graining is a branch of decorative work, it would never have fallen to its present debased standing as an industrial or decorative art. For the individual grainer who is not a decorator in a fair sense of the word, there is yet some hope. If, as we earnestly hope, the Painter-Stainers Company call the proposed conference of the trade in the autumn, to consider the Technical Education of the Painting Trade, it is within the bounds of possibility that many more scratchers may acquire a practical knowledge, not only of graining and inlaying, but of designing, decorating, and the control of colour, such as many able judges to-day can credit to LONDON DECORATOR.]

**Paint, etc.**—F. L. B. (*No Address*).—(1) One of the most useful and reliable spirit lamps for burning off old paint is the patent "Paquelin." Its price is 12s. complete, and it is a simple contrivance, of which any parts may be renewed. Its chief advantages are: burning in any position, its great heat, simplicity of use and lightness. The cost of working it is about a halfpenny per hour. (2) For silvered plate, G. Farmiloe & Sons, Rochester Row, London; or Cashmore & Sons, Bristol, might suit you. This firm make up a quantity of their own small sizes into very cheap overmantles, thus saving waste or loss on small sizes in their stock. Remember the quantity bought has much to do with the price to the trade buyer. (3) The sashes which, after being painted, do not run well, are probably overloaded with paint in the runners. Remedy: clean off with a plumber's shave-hook and then repaint with two bare coats of *hard-drying* paint.—F. P.

**Paint, etc.**—No. 305.—Respecting your cement wall-skirting—or "boards," as you term them—you do not say how long intervened between finishing the skirting with Parian cement and painting it; "at once" is rather an elastic term. If the Parian was painted on the same day, that is an error of judgment, I think. Moisture is certainly the cause of the paint not drying, and probably of the roughness "at the edges;" this again is not sufficiently plain for the purpose. Notwithstanding all that plasterers may say to the contrary, I should not, as a practical decorator, like to paint Parian until three days after finishing. If the "roughing in" mortar be thoroughly dry and hard, and a thin coating of Parian only skimmed over it, a day might be long enough before painting. I should say in your case the Portland was either not dry and the moisture effected the finish, or else that the moisture of the Parian, instead of drying inwards, was prevented by the nature of the Portland from so doing, and the damp, therefore, came out on the face of the work. Roughness is often caused, after a time, by chemical action of paint and wall.—F. P.

**Painter.**—MIGRATORY.—The South Wales ports, Swansea, Cardiff, and Newport, have good seasons of your trade, whilst the northern ports of Liverpool, etc., are large centres of work also. The wages paid to house-painters in these large towns is about 7d. per hour in the south, and 7½d. in the north. As to time of year, March and thereabouts is a good date anywhere, and, of course, between October and February is the worst period for a stranger. The most important factor of the whole question is the amount of your own trade ability, steadiness, energy, and common sense.—F. P.

**Repairing Waterproof.**—W. H. (*Rawden*).—In order for you to repair a mackintosh in which the seams are giving out, it is necessary to provide some naphtha spirit—such as is used by makers of india-rubber waterproofs—and a small tin of pure rubber solution, which is generally to be purchased at the waterproofer's. Having got these, spread out the mackintosh on a firm table, and with a small brush anoint the two surfaces of the seam, where it has come apart, with naphtha, which will soften the old rubber and dissolve the dirt and grease. Care must be taken not to let the naphtha extend beyond the lap of the seams; and after it has been on the surface for some ten minutes or so, you may then apply the solution, taking care not to smear it on the surface of the mackintosh, or to let it extend further than the lap of the seams. Now match the lap carefully and evenly along, and then with a heavy flat-iron press down, and bring the two surfaces into close contact, so as to squeeze out any air that may be between them; and when this has been neatly done, go on with the rest of the seam in a similar manner, until the repairs are completed, when the mackintosh should be spread out so as to allow the naphtha to evaporate and the joints to harden. It should be borne in mind that it is a very wrong plan to fold or bundle up a mackintosh after wearing, and put it away in that state until it is wanted again. So soon as it is taken off after use it should be hung up or spread out, so that the *inside* is exposed to the air; and thus the condensed moisture from the heat of the body is allowed to evaporate, and the damp or moist surface dries. One night of this treatment will ensure its being dry and fit for use the next day; and by practising this system the durability of such apparel will be largely increased, and the liability to the softening of the seams greatly reduced.—C. E.

**Electric Light.**—W. J. (*London, N.W.*).—To light up a room 12 ft. square, you should have three 10 c.p. lamps; these will absorb ½ h.p., and can be fed with current from a small dynamo or from a large battery; you would find the battery an intolerable nuisance. From your letter I should think that you have no idea of the cost and trouble of laying down a small electric light plant with batteries. I therefore advise you to read carefully the series of articles on "Model Electric Lights," published in WORK, Vol. II., Nos. 76, 82, 89, 92, 94, 97, 99, 101, and 104. This will tell you all about the batteries: how to make them, what acids to use, and how to arrange the lights. The whole set of numbers can be had from a newsvendor for 9d.—G. E. B.

**American Clocks.**—I. X. W. (*Glasgow*).—Do you mean American clocks with electric self-winding or clocks actuated by electricity? as I know nothing of the latter, whether any are made or no; but the former is, I know, and I daresay you can get them from J. J. Stockall, 6 and 8, Clerkenwell Road, London, as he is an importer of American clocks of every description. Write and ask him.

nd no doubt he will forward his price list.—A. B. C.

**Model Alliance Dynamo.**—H. O. B. (*Manchester*).—You have omitted to give full dimensions with the drawing of the carcase of your dynamo, so I must guess at parts of the measurements. You have omitted the armature altogether. Supposing this to be a solid shuttle or H girder of 3 in. in length by 2 in. in diameter, you might get on it from 27 yds. to 28 yds. of No. 20 silk-covered copper wire. Supposing you have a wire space of 2 in. above and below the core (this having a diameter of 1¾ in. and a length of 4 in.), you might get on it about 6 lbs. of No. 26 silk-covered copper wire. Then, if the armature is driven at a speed of 3,000 revolutions per minute, you should get a current of from 2 to 2½ ampères at a pressure of from 18 to 20 volts; and this would be enough to light up a 20 volt 8 or 10 c.p. lamp.—G. E. B.

**Model Manchester Dynamo.**—J. McA. (*Glasgow*).—The drawing of your model toy dynamo is very good, and enables me to judge exactly its merits. It will make a very pretty toy, but nothing more. You could get no practical results from a Manchester dynamo having field-magnet cores ⅝ in. by 1¾ in., and a wire space of only ¾ in. between the cores and the armature channel. I do not think you would get laminations so thin in the web as those shown in your sketch; and if you got them they would be useless, because they would not admit a sufficiently strong spindle. If this could be managed, you might get 25 yds. of No. 20 silk-covered wire on the armature. This would be equal to 16 yds. of active wire, and would develop a current of 14 volts with the machine driven at a speed of 3,000 revolutions per minute. But to balance this for any useful purpose, you should be able to wind the field-magnet cores with at least three times as much No. 26 silk-covered wire as they will now hold. With a solid wrought-iron armature wound with No. 20 wire, and No. 20 on the fields, you might make the machine into a motor.—G. E. B.

**Geneva Watch.**—R. I. (*Horsforth*).—Cylinder pivots are turned in the ordinary turns with a graver, and are then generally finished with a conical file and burnisher. The file and burnisher is like an ordinary flat one, but with just the corner rounded off; one corner being cut as the rest of the file, and the burnisher left smooth. These answer well enough for general work or jobbing, but for best work the pivots should be polished in with oil-stone dust, then rouge or red stuff, and finished with conical burnisher. Some pivots are made square, same as any other pivot, and then the shoulder turned off conical or at an angle of about 45° after the pivot is fitted and finished off. The ferrule generally used is simply a piece of brass with a hole in the centre slightly larger than the body of the cylinder and a groove turned in its edge to take the horse-hair of the bow. Take a bit of sealing-wax, and let a drop fall on the cylinder and fill it; this will make it stiffer and stand turning better. Then take the ferrule, make it hot enough to melt the wax, and slide it on the body of the cylinder. Clean the wax off the centre, and turn your pivots. When done, drop the cylinder and ferrule in a drop of methylated spirit, and gently boil it till all the wax is dissolved; then clean with pith and peg, and see that none is left inside it.—A. B. C.

**"How to Make a Dynamo."**—Messrs. Crosby Lockwood & Son, 7, Stationers' Hall Court, Ludgate Hill, E.C., request me to state that they are the publishers of the work under this title, to which reference is made in WORK, Vol. II., page 726.—ED.

**Violin Making.**—J. S. R. (*Glasgow*).—As you will have seen by this time, the Violin Making articles commenced in No. 105, the first number of Vol. III.

**Enlarging Drawings.**—J. W. (*Edinburgh*).—Considerable mystification seems to prevail on this subject. When a drawing is said to be *half* size, it is considered to be half full size; and the drawing will be placed on and within an area *half the length* and *half the width* of the area on which a full-size working drawing is placed, and so on for other sizes. You say you wish to know how to raise or enlarge a drawing from full to half size, and you instance a certain drawing in page 760, Vol. II. of WORK, enclosed in a square 6 in. by 4 in. Supposing this to be half size, and you wish to enlarge it to full size: divide the area into ½ in. squares, and prepare another sheet of paper by dividing it into 1 in. squares. As the length and breadth of your *half-size* diagram are 6 in. and 4 in., the length and breadth of the *full-size* diagram will be 12 in. and 8 in. "Ah," you will say, "but the *area* of the full-size drawing will be *four* times that of the original." Precisely so: but in enlarging and reducing, the length and breadth only are taken into account, and not the area. Again, if you wish to reduce your 6 in. by 4 in. diagram to half size, divide your paper into ¼ in. squares, and the length and breadth of the half size will be 3 in. and 2 in. respectively. For ¾ size, take ¼ of length and ¼ of breadth of original size for reduction. In this case the area will be ⅜th of original area; but, as I have said, in these cases you have only to deal with *length* and *breadth*.—ED.

**Hammering Hand Saws.**—ANXIOUS.—Purchase the Indexes to Vols. I. and II. of WORK. Much valuable information has already appeared upon the subject in WORK.

**Watch-Cleaning Tools.**—W. K. (*Heptonstall*).—You cannot do better than follow the instructions lately given in a series of articles in WORK. The tools you will require are really very few: a couple of watch brushes, a couple of small screwdrivers, an eye-glass to see the small holes, etc., are clean, and a piece of deal to make a small peg or two for cleaning the holes. The brushes, eye-glass, and screwdrivers may be got from the tool shops for about half a crown. You will want a bottle of watch oil for oiling it after it is cleaned. I find Ezra Kelley's is very good, and seldom use any other, either for watch or clock; also a little tissue paper to hold the pieces while brushing and cleaning. When cleaned, put under a glass, say a wine-glass, to keep the dust from them. When the brush gets dirty, rub it on a piece of chalk, then on a dry piece of bread. Use a stiff brush first, and finish off with a smooth one. Should you require any further instructions, write again.—A. B. C.

**Piano Stool.**—W. J. (*Portsea*).—As you do not wish your prospective piano stool to be of the screw species, I gather that you do not want an adjustable article. If my surmise be correct, you must select the height, etc., of the stool for yourself, taking an ordinary small chair as a guide. While preparing this reply, an "idea struck me," which idea, or the outcome of it, is shown in the adjustable back in Figs. 1 and 2. I give it as being useful by offering accommodation to anyone desirous of

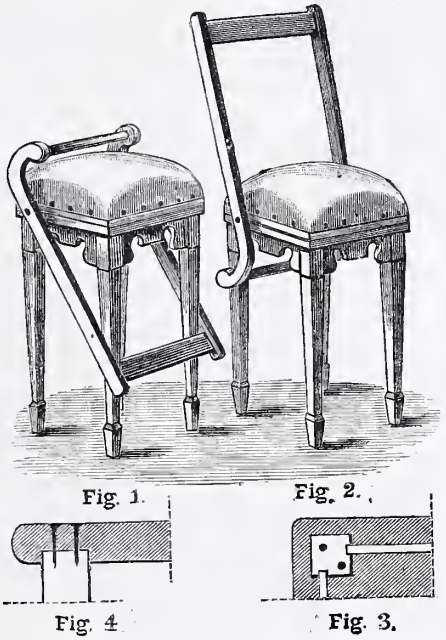


Fig. 1. Fig. 2.

Fig. 4 Fig. 3.

Piano Stool. Figs. 1 and 2.—Stool with Back down and adjusted respectively. Figs. 3 and 4.—Elevation and Plan of One Corner respectively.

obtaining further support than music stools generally afford. The back might be a fixture, but it will be convenient in more ways than one if made as I suggest. First, decide upon its most suitable height. Then hold it over the stool, as in Fig. 2, and shift it to various angles, keeping the pivot hole always on a level with the seat, to arrive at the inclination most likely to be appreciated as comfortable. The bottom spindle affords all necessary resistance when the back is being leaned against. I advise you to have a tolerably stout board, and mortise it within and adjacent to its four corners to receive the tops of the legs, which could then be screwed in position from the top of the seat-board (as in Figs. 3 and 4). Previously, slightly mortise the inner surface of each leg-block to receive the ends of the shaped pieces shown between the legs. Whether you omit a stuffed seat or use one, I recommend you to do as I say. Mr. Adamson's "An Armchair," lately published in WORK, will give you all necessary details relative to upholstery. Have a very wide framing to which the stuffing may be attached, and secure it to the solid seat-board by screwing from underneath and through the latter. Write again, with fuller particulars, if you want a stool with a more presentable appearance than this possesses.—J. S.

**Fret Machine.**—A. McC. (*Holywood*).—Ask your questions, and the author of the paper on the fret machine will answer you through "Shop."

**Enlarging Drawings.**—J. W. B. (*Huddersfield*). I am obliged to you for your reply to J. W. (*Edinburgh*) on this subject, but it is not the kind of reply that will be helpful to him. He has, moreover, been answered by myself, and the *modus operandi* made clear to him.—ED.

**Bass Bar, etc.**—B. T. E. (*Carlisle*).—The functions of the bass bar are both mechanical *and* acoustic. If the bass bar has been so much trouble to you, how have you gone on about the sound-post? as this little article performs functions equally as important as the bass bar.—B.

**Violoncello.**—J. D. (*Glasgow*).—The distances you desire to know are regulated, in the first place, by the length of the upper portion of the instrument: and secondly, by the position of the sound-holes. The length of string from "nut" to bridge should be about 27 in. Thicknesses depend not only on the area, but also on the quality of the wood. State which outline you intend to follow. Taken roughly, the length of the bass bar should be three-fourths of the length of the belly.—B.

**Violin Matters.**—L. F. (*Plymouth*).—The "figure" of the wood is natural, not, as you suppose, artificial. I do not know where Helmholtz's resonators can be purchased. I think the best way would be to take off the finger-board, and make the butt of the neck hot, say with a piece of hot iron. This would soften the glue; and by working the neck slightly from side to side, it would ultimately come loose. You should, before doing this, insert a sharp knife between the ends of the ribs and the neck, and also between the "tab" and the back of the "butt." Perhaps strong ammonia would remove the oil you complain of; but my idea is that the instrument is ruined.—B.

**Harmonium—Wood—Lubricant.**—W. W. (*Chelsea*).—Your numerous and varied questions should be written upon separate pieces of paper. Instructions on building an American organ will shortly appear.

**Scene Painting.**—J. M. N. (*Newcastle-on-Tyne*).—To become a professional "scenic artist" requires proper tuition, for which you have to pay a premium. The sum mentioned—viz., fifteen pounds—would indeed be low. There must also be the artistic taste, or all tuition is useless.—W. C.

**Earth.**—AUCKLAND.—We are unable, without making a qualitative chemical analysis, to give AUCKLAND any definite information as to the composition of the "yellow substance" contained in the sample of earth forwarded. If so disposed, you can have either a qualitative or quantitative analysis made. Analysts' fees vary; say one and a half guineas for a qualitative analysis, and two and a half guineas for a quantitative. We decline to recommend an analyst.—CHEMICUS.

**Incubator.**—W. S. (*Cambridge*).—A tray of water placed above the eggs, as suggested by you, would certainly be an improvement, were it not for the fact that the said tray would prevent the heat from tank being radiated on to the eggs. This being so, your plan will not answer. I would suggest a piece of sponge charged with hot water (replenished twice a day when airing the eggs) placed in a shallow cup in centre of egg drawer. Water would probably slop, hence the sponge.—LEGHORN.

**Clock.**—LOOKER ON asks, "What is the best clock for one to buy—either old grandfather or American, or any other make? price no object; a really good substantial article. How to know a good one when shown of any make?" It would have been more satisfactory if LOOKER ON had stated for what position and purpose he desires a clock, as that makes a great difference as to size and construction. But as he appears to put a general question, I will answer it in a general way. It may be taken as undeniable that high-water mark as regards time-keeping qualities is reached by clocks having the shape of the grandfather type. The best results are to be obtained from clocks with weights and long pendulums, as distinguished from those with springs and short pendulums. A common grandfather clock, if placed in a steady position and well regulated, should be made to keep better time than an expensive mantelpiece or bracket clock with springs and short pendulums. The most accurate style of clock is that used by watchmakers for "timing" purposes, and generally known as a "regulator." The best regulators have comparatively light weights—their mechanism being so delicate as to require little driving—and long mercurial pendulums. A first-class regulator may cost as high as £100. But LOOKER ON, unless he is an astronomer, can scarcely require anything so fine as this. I would advise him to try and pick up a second-hand watchmaker's regulator. A good one can often be had for from £10 to £20. Many good watchmakers have two, and even three, regulators, in which case one of the clocks will be that which they began with in their early days, and which, though not quite up to the mark from a scientific point of view, would be more than first-class for ordinary private purposes. Watchmakers are often disposed to part with a clock of this sort. As regards the last query, "How to know a good one when shown of any make?"—the obvious reply is that the way to know a good clock is to thoroughly understand the mechanism of clocks. Without such technical knowledge, neither LOOKER ON nor anyone else can tell a good clock from a bad one, except as far as the case and the outside appearance are concerned. The only general advice I can give him is that he should select a clock with weights and long pendulum. For the rest, he must either rely on his own technical knowledge or on the honesty of some reliable person in the trade.—HERR SPRING.

## III.—QUESTIONS SUBMITTED TO CORRESPONDENTS.

**Window Flower Boxes.**—J. K. T. (*Perth*) writes:—"Could any reader give me some designs for window flower boxes in WORK? The season is now coming on for flowers to be put in the windows."

**Teasing Hair.**—A. A. (*Edinburgh*) writes:—"Will any reader give me information in regard to a machine for teasing hair by motive power, or, if they can be bought ready made, the maker's name and address? I would not like a very large machine—one capable of teasing 80 lbs. to 100 lbs. per hour. I would prefer to make the machine, if not too intricate."

**Pen.**—J. R. (*Walton-le-Dale*) writes:—"Will any reader tell me how to make pens that require no ink? I have seen one, and should like to know all the materials for making them."

**Air-Proofing.**—F. G. B. (*Brixton*) writes:—"Can any reader inform me how to render calico or linen perfectly and permanently air-proof?"

**Wood and Ivory Balls.**—F. G. B. (*Brixton*) writes:—"I shall be obliged if any reader can tell me if turned wood balls can be used for playing billiards (as ivory balls are so expensive), what kind of wood is suitable, and where could I get them?"

**Black Lead.**—F. P. (*Leeds*) wants to know if any of our readers can tell him how manufacturers put such a polish on blocks of black lead? He has made black lead into blocks, but cannot get a polish on the outside. A recipe for a good stove polish would be esteemed.

**Gas Engine.**—H. R. P. (*Nottingham*) writes:—"I shall be glad to know where I can obtain castings, instructions, and working drawings for making small gas engine."

**Fountain Pen.**—A. B. (*London, S.E.*) writes:—"I would like to construct a fountain pen; if you or your readers could give me sketches and particulars, you would much oblige."

**Brass Whistle.**—CLARIONETTE PLAYER writes:—"Would a correspondent kindly tell me how to make a brass whistle in as deep a tone as it is possible to make it, giving accurate size and pitch of holes? I have several pieces of good tubing, and every size up to ¾ in. internal measurement."

**Setting out Teeth and Cogs.**—X. (*Liverpool*) writes:—"I would consider it a great favour if you would give a plain method of setting out and proportioning the teeth of wheels, bevel cogs, and wooden cogs; and if any figures are wanted, let them be plain."

**Combined Bench and Tool Chest.**—T. R. B. (*Wandsworth*) writes:—"Will any reader kindly give me a design and instructions how to make a simple bench and tool chest combined, about 5 ft. 6 in. long, and 1 ft. 6 in. wide, to stand in corner of room, one side and one end against wall, but cased in and constructed to take apart easily if required?"

**Brush Making.**—B. S. (*Acton*) writes:—"Would any reader kindly inform me in 'Shop' where I could procure the wooden backs or handles for clothes brushes ready bored for receiving hair? Also the wire for pulling in same? I have a quantity of horse-hair I would like to make into brushes if the backs are procurable."

**Cattle Marks.**—J. H. M. (*Meath*) writes:—"I will feel obliged to be informed if there is any dye which would answer for marking cattle—a substitute for the tar brand, which does not last once the hair grows; if it would mark the skin, all the better. As there are so many cattle now that have had their horns taken off, it is hard to know how to mark them so that the mark will last for any length of time."

**Fire-Lighters.**—PHŒNIX writes:—"I shall be grateful if any reader can give full instructions for making tire-lighters (composition)."

**Colouring Photographs.**—A. F. M. (*Glasgow*) writes:—"I employ a good deal of my spare time in colouring photographs by the crystoleum process; and my experience (a pretty long one) is that the fixing on the glass with starch is not satisfactory. No matter how carefully done, glistening specks appear; it takes up a great deal of time; you are very liable to break the glass or tear the picture; and in rubbing down, if you intend to wax the picture, the photo is liable to lift in places, or, if you use a cleaning medium, it lifts in places at the edges. Although I have done many successful pictures, this is my experience; and I would be obliged if some of your numerous subscribers could favour me with a recipe for a cement which will fix the picture firm, quite transparent, without speck, and will not require the trouble and danger of rubbing out spots or air bubbles for any length of time, like starch."

**Checkering.**—CHECKERED writes:—"I should feel obliged to be informed how best to checker leather; also the tools or appliances requisite for the purpose."

**Petroleum Motors.**—CONSTANT READER writes:—"I should feel obliged if any of our readers would give me information on the above—their working, and the advantages they have over gas motors."

**Mandrel Head.**—M. H. (*Maiden Newton*) writes:—"I have just completed a mandrel head, the mandrel running through one brass bearing, and supported by a back centre. I now wish to make a 5 in. head, with the mandrel running through both front and rear of the head. Can any correspondent tell me if borings through the solid cast iron will prove a sufficiently permanent bearing, or had I better have brass bearings? I also think of adopting the parallel bored collars of traversing mandrels, though it is not my intention to add guide screws. Is this plan or a back centre best for a lathe for general use?"

**Photo-Lithography.**—PEN AND INK writes:—"I shall feel much obliged to any reader who will give me information on any branch of lithography or zincography."

**Bass.**—E. B. M. (*Tunbridge Wells*) would be obliged to any reader of WORK for information as to where he could purchase a small quantity of bass (I think it is called), the same as brooms are made of; it is also used for sweeps' machine brush-heads.

**Briar Wood.**—J. R. N. (*London, N.*) writes:—"Will any reader kindly inform me of a dealer in London from whom I can obtain briar root for pipe making?"

## IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**Leclanché Battery.**—F. S. (*Carlisle*) writes, in reply to C. F. W. N. (*Forest Gate*) (see page 78, Vol. III.):—"You will be able to get a Leclanché battery of two cells, all complete, of J. Halhead, chemist, Carlisle, for 3s., which will answer the purpose for which you require it."

**Preserving Ice.**—M. (*Bishop Auckland*) writes, in reply to J. K. (*Middlesbro'*) (see page 78, Vol. III.):—"Make a box narrower at the bottom than the top, and bore holes in the bottom to allow water to run out. Set this on 1 ft. in thickness of faggots or reeds, over a trapped drain in the cellar. Line the inside 1 ft. thick with straw, and pack the ice in, broken into small pieces, adding a little water to make it freeze into a mass. Some advocate the addition of a little salt to form a freezing mixture. Cover with 1 ft. thick of straw; then cover box at least 2 ft. thick all round with non-conducting material (chaff or sawdust). You want to exclude all air, and allow any water to drain off at once."

**Tin Labels.**—THOMAS STEPHENS (*Paradise Street, West Bromwich*) writes, in answer to LABEL (see page 830, Vol. II.):—"We are in a position to supply any kind of stamped tin labels very cheaply."

**Tin Labels.**—W. NEEVES (*Southgate Street, Leicester*) writes, in reply to TIN LABELS (see page 830, Vol. II.), that "he makes a specialty of tin labels."

**Enamelling Slates.**—M. (*Bishop Auckland*) writes, in reply to J. D. (*Holyhead*) (see page 46, Vol. III.):—"The slate is polished smooth, then japanned or painted till of the required colour; the japan is hardened by stoving or baking. It is then smoothed with pumice-stone, and polished with rotten-stone. You might procure a book on the subject from Spon, 125, Strand; or Batsford, 54, High Holborn."

**Enlarging Drawings.**—G. M. (*Brixton*) writes, in answer to J. W. (*Edinburgh*) (see page 14, Vol. III.):—"The following rule will give the dimensions required: If a drawing is wanted half as large again, 'square each side, add half, and extract the square root.' Thus, suppose the original is 4 in. by 6 in.; the square of 4 is 16. To this add half (8), and this will give 24; the square root of this is 4·898 in., which is the measure of the shorter side. The longer side can be found in the same way, and will be found to be 7·348 in. If the drawing is wanted to be reduced, say to half the size, 'square each side; halve each, and extract the square root.' The sizes will be found to be 2·828 in. and 4·242 in. Both the above give the exact surface within a hundredth part of a square inch. Of course, they can be got nearer than this by carrying out the decimals farther. If J. W. wishes to know how the above rule is obtained, it can be demonstrated thus: In the case of enlarging, let $x$ represent the size we want for the smaller side; then $x + \frac{x}{2}$ (because 6 is 4 and half of 4) represents the longer side; and then $x \times (x + \frac{x}{2}) = 36$. This, worked out, gives $x$ equal to the square root of 24, which is the same as above."

**Stain.**—DOWN writes, in reply to S. S. (*Salford*) (see page 44, Vol. III.):—"To stain birch a mahogany colour, there is no simpler plan than dissolving some Bismarck brown in hot water and rubbing it into the wood with a rag. If the colour is too red, he can add a little vandyke brown to darken. It can then be polished in the usual way. I have often used the Bismarck brown alone with good results."

**Castings.**—H. E. (*London, N.W.*) writes, in reply to K. M. (*No Address*) (see page 14, Vol. III.):—"If you can get castings at 7s. per cwt., don't attempt to cast them yourself in such small lots as 1 cwt. or 2 cwt. per day, as they will then cost you half as much again. If you were casting tons instead of cwts. you could not do them much cheaper."

## V.—BRIEF ACKNOWLEDGMENTS.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—H. D. (*Hull*); A WORKING MAN; P. Q.; THE VICTOR CYCLE CO; H. W. (*London, S.W.*); SOCRATES; W. S. S. (*Bristol*); T. M. (*Southampton*); A. H. W. (*Newcastle*); A. B. & Co. (*Belfast*); J. B. (*Leicester*); E. C. O. (*London, S.W.*); S. H. (*Rochdale*); LETTER CUTTER; H. S. (*Ipswich*); A. B. C. (*Newton Abbot*); INCUBATOR; H. H. L. (*Higher Bebington*); LITHO; G. S. (*Craven*); NEW READER; W. H. O. P. (*London, N.E.*); A. W. (*Aberdeen*); CYLINDER; J. W. E. (*South Darenth*); T. N. (*Halifax*); W. H. (*Penzance*); L. W. L. (*Wolverhampton*); PORTABLE HARMONIUM; A. R. (*Blackburn*); WUEDDLE; F. E. B. (*Hull*); R. V. B. (*Peckham, S.E.*); RULER; G. H. S. (*Kensington*), Z. Z. Z. (*Wednesbury*); T. A. (*London, S.E.*); J. S. (*Amsterdam*); T. F. (*Tamworth*); W. G. M. (*Limpharan*); A REGULAR SUBSCRIBER; H. S. # A WONDERFUL MEDICINE.

# BEECHAM'S PILLS

Are universally admitted to be worth a Guinea a Box for Bilious and Nervous Disorders, such as Wind and Pain in the Stomach, Sick Headache, Giddiness, Fulness and Swelling after Meals, Dizziness and Drowsiness, Cold Chills, Flushings of Heat, Loss of Appetite, Shortness of Breath, Costiveness, Scurvy and Blotches on the Skin, Disturbed Sleep, and all Nervous and Trembling Sensations, &c. &c. The first dose will give relief in twenty minutes. This is no fiction, for they have done it in countless cases. Every sufferer is earnestly invited to try one Box of these Pills, and they will be acknowledged to be

**Worth a Guinea a Box.**

FOR FEMALES THESE PILLS ARE

"A priceless boon, a treasure more than wealth; the banisher of pain, the key to health."

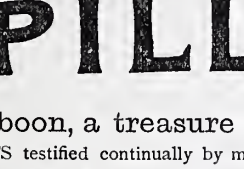
These are FACTS testified continually by members of all classes of society, and one of the best guarantees to the nervous and debilitated is,

***BEECHAM'S PILLS have the Largest Sale of any Patent Medicine in the World.***

Prepared only by the Proprietor, T. BEECHAM, St. Helen's, Lancashire, in Boxes 9½d., 1s. 1½d., and 2s. 9d. each. Sold by all Druggists and Patent Medicine Dealers everywhere. *N.B.—Full Directions are given with each Box.*

**FLUID** WATER RESISTING **GLUE** (*Patent*) PATENT TINS.

*Invaluable for all Out and Indoor Repairs.*



**FLUID** WATER RESISTING **GLUE** (*Patent*) PATENT TINS.

No Brush—No Boiling—Will securely join Wood, Glass, China, Metals, &c.

*By Post, 8d. and 1s. 3d. per tin. Through Ironmongers, Chemists, Chandlers, &c., 6d. and 1s. per tin.*

Manufactured only by THE WATERPROOF GLUE CO., 62, Dale St., LIVERPOOL.

LEE'S ILLUSTRATED CATALOGUE OF SELECTED

**AMERICAN TOOLS and MACHINERY.**

Screw Cutting and other Lathes, Chucks, Slide-rests, Lathe Dogs, Polishing Lathes, Drilling Machines, Drills, Parallel and Instantaneous Grip Vices, Screw Stocks, Taps and Dies, Saws, Wrenches, &c., &c., specially selected from the best American Manufacturers, therefore of the very highest quality, and at low prices. *Send for Illustrated Catalogue, 150 Illustrations, price 6d., post free.*

MODEL STEAM ENGINES, and Complete Sets of Castings of same, of every description, from the smallest to powerful Engines.

**LEE'S ILLUSTRATED CATALOGUE.**

New and Revised, Prices greatly Reduced. To Amateurs the most useful book extant, and largest and best Catalogue in the Trade. 64 pages, 110 Illustrations, price 6d., post free. Please state whether American Tool or Model Steam Engine Catalogue is required when ordering. ONLY ADDRESS— *76, 77, and 78a, HIGH HOLBORN, LONDON, W.C.*

Gateway entrance directly opposite the Inns of Court Hotel. Awarded Prize Medal International Inventions Exhibition, 1885. Please name this Paper when writing.

**DELICIOUS TEMPERANCE DRINKS.**

MASON'S NON-INTOXICATING BEER. MASON'S WINE ESSENCES.

These Essences produce in a few minutes a delicious Temperance Wine or Cordial, Ginger, Orange, Raspberry, Black Currant, Lime Fruit, etc. One Tablespoonful of Mason's Extract of Herbs makes one gallon of Splendid Beer, refreshing and non-intoxicating.

A Sample Bottle of either Essence or Extract sent on receipt of 9 stamps, or a bottle of each for 15 stamps.

# FRETWORK FOR AMATEURS OF BOTH SEXES AND ALL AGES.

Eclipse Design, No. 102.

Wall Bracket. Price 6d.

THE MOST PROFITABLE AND FASCINATING OF ALL HOME PASTIMES. EASILY LEARNT.

J. H. SKINNER & Co. having *Dissolved Partnership*, are offering their *Enormous Stock*, including 250,000 FRETWORK PATTERNS and 100,000 ft. of Solid and Three-Ply FRETWOOD, Veneers, &c.; 1,000 Gross of FRETSAWS, besides an immense quantity of TOOLS, OUTFITS, &c., as a special inducement to their customers to order at once.

**4,500 1s. Books of Fretwork Patterns**, each containing Twelve Large Sheets, beautifully lithographed, none of which would be sold retail at less than 2d., and many at 3d. and 4d. each; also

**1,200 2s. 6d. Books of Fretwork Patterns**, containing Twenty Sheets, 19 in. × 12 in., of new designs, many of which would retail at 6d. each. These Books,

**£375 in Value, will be GIVEN AWAY.**

Amateur customers ordering 5s. worth of designs from Catalogue will be presented with one of the above 1s. Books. Those ordering 10s. worth will receive a 2s. 6d. Book.

**An Allowance of 10 per Cent.** *in goods* will be made on all mixed orders for Wood, small Tools, Saw Blades, and Designs, amounting to 10s., and **15 per Cent.** on orders amounting to 20s. and upwards. NOTE.—*This reduction does not apply to Treadle Machines.*

N.B.—A SPLENDID OPPORTUNITY FOR BEGINNERS.

**Complete Fretwork Outfit**, comprising 12-inch Steel Frame, Forty-eight Saws, Awl, File, Four Designs (with sufficient Planed Wood and 1s. Handbook on Fretwork). **An Archimedian Drill**, with brass handle and Three Bits, will be **SENT GRATIS** with each Set. Post free for 3s. 6d. Outfits on Card, 1s. 6d. and 2s. 9d., post free. 6 ft. 2nd quality assorted planed Fretwood, 1s. 9d.; post free, 2s. 6d. 12 ft. ditto, ditto, 3s.; post free, 4s. 3d.

**SKATES!!!**—EVERY PAIR WARRANTED.—Sizes, 7½ in. to 12 in. No. 1, Unpolished Beech, 10d. per pair. No. 2, Polished Beech, 1s. 6d. per pair. No. 5, "Acme" pattern, all steel, 3s. per pair. No. 7A, "Caledonia" pattern, self-adjusting, one screw fastening the whole skate, the best principle, 6s. per pair. No. 8, Metal frame, with strap complete, 1s. 9d. per pair; postage, 5d. per pair. These are not rubbish; we warrant every pair.

NEW CATALOGUES of Machines, Designs, Wood, Tools, etc., with 600 Illustrations and full instructions for Fret-cutting, Polishing, and Varnishing, price 4d., post free. A Specimen 6d. Fretwork Design **SENT GRATIS** with each Catalogue; also a List of Designs, Outfits, Tool Chests, etc., at Greatly Reduced Prices to clear.

N.B.—All orders *must* be accompanied by remittance. APPLY—

# Cassell's Storehouse of General Information.

FULLY ILLUSTRATED WITH HIGH-CLASS WOOD ENGRAVINGS, AND WITH MAPS AND COLOURED PLATES.

*** *With* Part 1 *is presented a Series of* 4 *Coloured Plates, illustrating in a novel and attractive manner* Botany, Geology, Architecture, *and* Physiology.

"'Cassell's Storehouse of General Information' will be the work of specialists in every branch of knowledge, and, judging from the first part, will be one of the most comprehensive works in the range of popular encyclopædic literature. The sixty-four pages of this part are crowded with admirably condensed information. . . . The number is profusely illustrated, and contains a folding map. There is, besides, an important extra feature in a series of four coloured plates, elaborate in detail, illustrative of as many branches of popular science."—*The Rock.*

"Promises to be a most valuable dictionary of universal knowledge. Its articles are short, as a rule, but they are sufficient for their purpose. Some of them extend to several columns, as 'Agriculture,' 'Afghanistan,' and are all written with great clearness. . . . The work, so far, highly deserves commendation."—*Educational News.*

"Its quality seems good, its style easy and conversational, and its illustrations—judging by the excellent physical map of Africa—of a high class. With this first part is given a large sheet of four remarkably well-executed coloured plates, representing Architecture, Botany, Geology, and Physiology."—*Christian World.*

"A good book of reference, giving in a comparatively small compass the gist of that information which is absolutely necessary in an age of progress like the present, when the intellectual standard is considerably higher than that of a generation ago, and when the competitive race for life leaves men less time than ever for study."—*Methodist Times.*

"A comprehensive book of reference, freely illustrated, and the conjoint work of a number of men especially qualified for their task."—*Literary World.*

"'Cassell's Storehouse of General Information' is a veritable encyclopædia of useful knowledge. . . . Beautifully coloured botanical, physiological, architectural, and other plates are given with the first number."—*Independent.*

"The book is compiled from most trustworthy sources, the matter relating to science and art being contributed by specialists and written up to date. It is illustrated with capital wood engravings, maps, and coloured plates."—*The Star.*

### A CORNER CLOSET FOR THE HALL.

BY MISS F. M. GARDINER.

A VERY fair estimate may generally be formed of the powers of administration of the mistress of a household by the first glance we obtain as soon as the front door is opened. And it will be readily granted that the hall of an ordinary middle-class house can be rarely considered

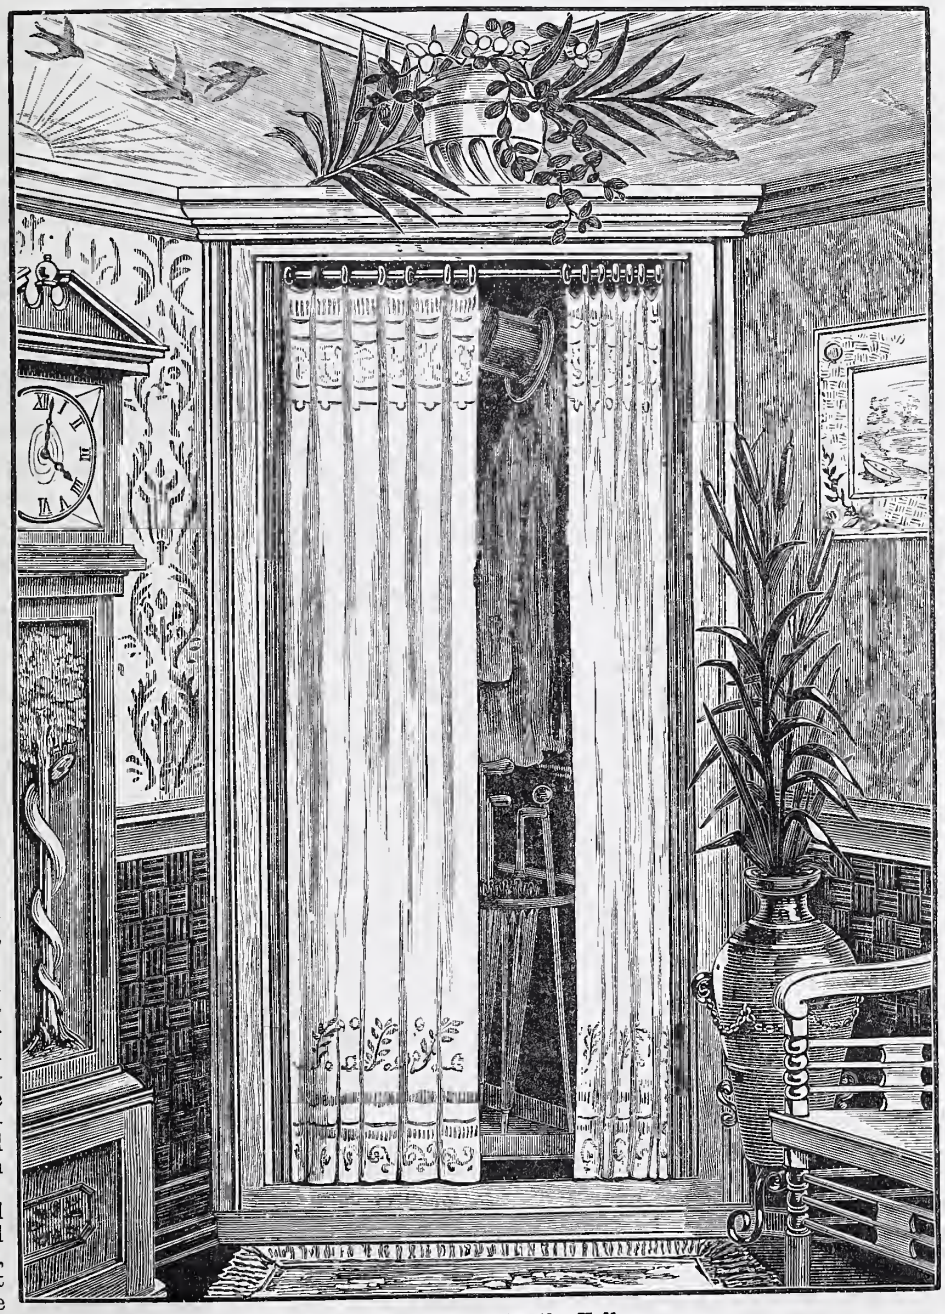
"A thing of beauty, and a joy for ever."

On the contrary, if the family is large, it often becomes a receptacle for the cast-off wearing apparel of its different members, and the repository for dripping umbrellas, tennis rackets, cricket bats, and various articles too numerous to mention, which might with advantage be transferred to a more suitable position.

To avoid the row of coats and hats, in a more or less dusty condition, as a rule found here, a small wardrobe, like the one illustrated, might be easily substituted, even in a hall of limited dimensions, for the pegs which one invariably finds there.

This might be placed in a corner, if the hall be large enough, or against a side wall, when it is not of sufficient size to admit of such a structure as I have suggested in the accompanying illustration. The framework and top could be made of any appropriate wood, or, where cost was a consideration, simply stained or painted to match the other fittings.

The interior should be liberally supplied with hooks and pegs, and the lower part with a rail and movable tray for umbrellas, also a small drawer for brushes, etc. These would be effectually hidden by curtains, attached to a brass pole by rings, yet, at the same time, be easily accessible. Such a piece of furniture would be welcome in any house, and is so simple in construction that it would be well within the power of even an amateur workman to execute.



A Corner Closet for the Hall.

From what has been said above, as well as from the illustration itself, it will doubtless be understood that the form of the closet must depend entirely on the size and shape of the hall, and that for the corner closet the hall must bear the semblance and proportions of a room of fair width, rather than those of the narrow passages that are too often misnamed by the application of this dignified title. Yet even in the passage itself, properly so called, it is often possible to introduce an arrangement of this kind, by affixing side frames of stained wood, with panels of cretonne stretched over thin board, or even millboard, on either side of the row of hat pegs and coat hooks to be found on the wall, covered in with boarding at the top and kept in position at the bottom by a slip of wood extending from frame to frame, and fixed to them at each end. A cornice should connect the frames at the top, and within the cornice should be a rod to carry the curtains that screen the hats and coats from view after the manner of the Portable Wardrobe, figured and described in page 150. Here is a rough outline for a useful article of house furniture, and it is assumed that those intending to make it will have a sufficient knowledge of carpentry to enable them to proceed without my giving step by step details. To those who are without this knowledge, a careful perusal of much that can be found in WORK concerning the elementary stages of carpentry will soon fit them for making this simple closet. For its decoration the enamels of the Foochoo Co., Aspinall, and others, will be invaluable.

## THE TAMBOURINE, AND HOW TO MAKE IT.

BY OMADAUN.

A Pretty Article for Decoration—Its Construction—The Hoop—Cheap Jingles to be avoided—Brass Nails of Two Kinds—Choosing a Vellum—How Stretched—Utilising a Cheese Tub for Making Hoop—Suggestion for Decoration in Water Colours.

This is an article which of late years has soared high, and attained to an eminence for decorative purposes never dreamed of in its humbler days, when—so far, at all events, I believe, as this country is concerned—it was the almost exclusive monopoly of the black cork fraternity. Now, a good tambourine, well painted, is a really pretty object, but the so-called art tambourine supplied by the fancy shop is an abomination, not worth bestowing good work upon; whilst the genuine article is rather costly—at least, in proportion; and it is so easy of construction, that I hope a few hints upon the subject may not be considered out of place in these pages.

I will first deal with the tambourine proper, if I may so call it. It is evident that this must be stoutly made, or it will not hold together long, seeing the arduous duty that it has to perform; and, although I have made one from an old cheese tub, and used it too, I do not advise that material, except for one intended for ornament only, when it may be used if economy is a consideration; of which, more anon.

A good solid hoop of oak or ash, steamed and bent to a circle, ready for joining and finishing, can be bought at many instrument makers' for about one shilling, and it will be far better to buy one of these than to attempt to bend one from the straight piece, which is hardly practicable for an amateur to accomplish satisfactorily. Choose a hoop of as near a true circle as possible, and a convenient size will be 11 in. diameter and 2 in. deep. The two ends should be tapered, and overlap for about 4 in.; they are then glued, and firmly cramped together. When set, this joint is smoothed off with plane and rasp, and the hoop nicely finished with sandpaper; the joint should then be hardly perceptible. The top edge may now be slightly rounded, and six slots cut at equal distances for the jingles; this is easily done with a fret saw, or they can be drilled out and finished with a file; they should not be cut quite in the centre of the hoop, but a little nearer to the bottom edge. With regard to the jingles, avoid cheap ones; the cost of the best is so little, a few pence only per pair, and the look of the tambourine is so materially enhanced by them, that they are well worth the trifling extra outlay. For my own part, I like an ebonised hoop, and plated jingles, but this perhaps is a matter of taste; if preferred, the hoop can be either stained or left its natural colour, and polished. Mark a line round the top, about ¼ in. from the edge, and drill a row of holes all round, about 1 in. apart: these are for the nails to be pushed through when stretching the vellum. There are two sorts of these nails to be had—some with brass heads and iron shanks, about the thickness of a panel pin, the others being entirely of brass; the former are better finished, but the latter sort are easier to clench, and are the ones generally used.

In purchasing a vellum, choose a good stout one, which is of an even thickness throughout; it should be about 3 in. wider in diameter than the hoop, to allow for turning over and finishing. Place it in a basin of water for a minute or two, not more; then take out, and allow the superfluous water to drain off. Pierce a hole in it with a stout needle or awl, about 1 in. from the edge, push one of the nails through, and then through one of the holes in the hoop, and clench it on the inside; pull the vellum tightly across, and put in a nail on the other side; now put one in on each side again, between the first two, and proceed in the same way until all the nails are inserted. The vellum must be stretched well before each nail is put in, and perhaps the easiest way to do this is to pull it with a pair of pincers. If the holes have not been drilled too large, and the nails fit tightly, it will not be necessary to clench each one as it is put in, but they will hold quite well by being simply pushed through, and can be clenched when they have all been inserted. Cut away the superfluous vellum to an even margin with a sharp-pointed pocket-knife, and when dry, it should be as tight as a board, making as good a tambourine as you can wish for. I need hardly say that the jingles are fixed by a wire or pin running through them. If, however, one is wanted for ornament only, there is no need to make it of quite such solid materials; and here, if, as I have said before, economy is a desideratum, a cheese tub may be utilised. The grocer will supply one probably for the asking: it must not be too thin, or it is likely to buckle and come out of shape when stretching the vellum, so choose as stout an one as you can get; there will be no difficulty in forming a circle of the required size from this material. The vellum, also, need not be so stout as our former one, and if the whole is to be painted over, an old parchment deed may be used if there is one side not written upon, which I need hardly say must be uppermost; but a clear vellum will look better if it is intended to let it show as a background for the painting. Put in six pairs of jingles, good ones, the same as before; they go a very long way towards giving a genuine look to the tambourine. The hoop can be either painted black or in colours, or left natural, according to taste. If a cheese tub has been the material used, it will probably look best painted, and as this wood is likely to be rough and coarse in the grain, it may have to be filled in with plaster of Paris, mixed with water to the consistency of thick cream; rub this in with a rag, and when dry, clean off with sandpaper. This tambourine will have to be painted upon in oils, but I would suggest that instead of a vellum being used, a piece of good paper—such as "Whatman's"—could be substituted, upon which a water-colour drawing could be executed. I have not myself tried this plan, but I think there would be no difficulty in stretching the paper on when damp, and perhaps a little glue round the edge would be advisable, the nails, of course, being used, but chiefly for ornament.

This would not perhaps be so durable as the usual style, but it would at all events be a variety, which has a certain amount of charm in itself always, and a little water-colour sketch can be so easily and quickly executed that it would not be a matter of great difficulty to renew the painting. The nails should not, in this case, be clenched, so that they could easily be withdrawn, and a fresh piece of paper stretched when required.

Although I have used a tambourine made out of a cheese tub and stout drawing paper, as I have said, it must be borne in mind that this form of the instrument, though serviceable enough for decorative display, is by no means so useful for musical purposes as one made of vellum.

## THE VIOLIN: HOW TO MAKE IT.

BY J. W. BRIGGS.

Purfling—Carving-Block—Modelling—Grooving for Purfling—Purfling Waists—Mitres in Purfling—Scraping and Sandpapering—Ribs—Removal of Ribs from Inside to Outside Model—Waists—Hollowing Back—Sandpapering Back, etc.—Cutting Sound-Holes in Belly—Hollowing Belly—Fitting Bass-Bar—Rounding Top, etc.—Gluing Ribs to Back—Gluing on Belly.

**Purfling.**—Having got thus far, we may now turn our attention to the ornamentation of the instrument, known as "purfling."

*Carving-Block.*—A carving-block is now required, and as they are inexpensive and you can get on so much better, you had better make two. Get two pieces of deal 15 in. by 9 in. by 1 in. or 1½ in., plane one side of each piece true, and mark the outline of the ribs on each planed side, and have the shapes cut out by a band saw. In both rough sides bore a small hole central of length and width, and "tap" or make a thread in it with the point of the carver's screw, using the square hole in the wing nut as a wrench. The back and belly should each be glued on one of these carving-blocks, by putting a dab of glue about 3 in. from each end, and cramping them to the blocks with iron cramps or with hand-screws. In a few hours these will be set, and you can proceed with the rough modelling and purfling.

*Modelling.*—Turn the carving screw firmly into the block on which the back is glued, put the screw through the bench, and turn the nut up to the under side of the bench. It is better to work the back first, as it will be first required. Now with smooth plane, *across the grain*, give the arching, roughly, of Fig. 9. Afterwards, with No. 4 gouge take off the thick parts of the wood, and aim to give a curve from the ⅜ in. line to the centre joint.

*Grooving for Purfling.*—The purfling tool must now be set with one blade $\frac{5}{32}$ in. from the brass roller, and the other exactly $\frac{1}{16}$ in. further away, and screw it firmly up. A double line must now be traced all round, distinct, but not too deep; the lines must then be cut deeper with one of the fine, keen-pointed knives (B, Fig. 5, p. 85), always cutting off the end of the grain. The grooves should be cut to a depth of $\frac{1}{12}$th of an inch, which is the depth the purfling should be.

*Purfling Waists.*—The piece of wood between the lines in the *waists only* should now be taken out with a router (C, Fig. 5), the greatest care being taken neither to go through or split any pieces from the edge of the groove. The dark line in Fig. 11 is intended to represent the way in which the groove should be cut when ready to receive the purfling. A piece of purfling should be cut to completely fill this groove; when fitted, run glue all through the groove, and tap the purfling into its place with a small hammer. With a sponge dipped in hot water remove the glue, and rub the purfling more perfectly down with the tail end of the hammer. When both waists are purfled, lay the back aside to dry, and proceed in like manner with the belly. It will be remembered that the "tab" prevented the gauge from going completely round the back. The lines must therefore be joined with the compasses, care being taken to preserve the sweep or curve.

*Mitres in Purfling.*—The entire grooves will now be ready for cutting, and the utmost care will be necessary in making

the mitres at each corner, as also the joints in the pieces of purfling. The purfling already in the waists will require to be cut down in the direction shown by line *a a* (Fig. 11). Your next business is to make the mitres on the pieces of purfling, which must be done so well that the points of both inner and outer blacks as well as the whites finish together at a very acute angle. It is said that in the Cremonese purfling, the outer black is run a little beyond the meeting point; the delicacy of this apparently trifling process will be best appreciated by those who try to do it. After all the mitres are fitted to their places, make bevels at the other end of each piece in such a manner that when glued in no joint will be perceptible. I find it more convenient to put the upper and lower rounds of purfling in, each in two pieces, as the mitres can be made much safer and better than when only one length is used. When purfling the belly, do not attempt to make joints at either top or bottom; the insertion of the neck in one case, and of the bottom nut in the other, will obviate all necessity for doing so. When all the purfling is laid and rubbed down, sponge the edges all over with hot water; this will not only take off all glue from the surface, but will make the purfling fit better. Now put aside to dry while purfling the belly, which being accomplished, take the back in hand again. Open the compasses to $\frac{5}{16}$th of an inch, and trace a line round the back that distance from the edge. Fix the screw through the bench as before, and, following direction of arrows in Fig. 2 (p. 5), with No. 6 gouge cut a hollow between the compass line and outer edge of purfling all round, leaving the corners B, B, until last. If by mischance you happen to make the edge of the hollow irregular, go round again with the gouge, this time a little over the purfling, and cut in opposite direction to the arrows. When the hollow is satisfactorily carved, complete the lengthways arching (Fig. 9) with flat gouge and oval plane. Then give (at A, Fig. 9) the requisite form across the waist with No. 4 gouge; after having done this, with gouge No. 2 and small planes gradually "melt" the archings into the hollow all round, taking care that the hollow be not damaged; if your wood cuts rough, reverse your cutting. Never attempt to carve the wrong way of the wood.

*Scraping and Sandpapering.*—With the scrapers, very sharp, take out all plane marks, and with sandpaper No. 1½, used on cork rubbers, sandpaper all over, but do not spoil the modelling in doing this. Brush off all the dust, and sponge all over with cold water; and whilst the back is drying, model the belly in the way described. By the time this is finished the back will be ready for another scraping and sandpapering—this time with finer paper. Should any inequalities be shown up by the wetting, these must be adjusted with the scrapers before papering. After this operation is performed, again sponge the work over, as ultimately by doing so you will obtain greater solidity, and less liability of the grain rising when the varnish is laid on. The belly should now be attended to in the same way.

**Ribs.**—The next step will be the manipulation of the ribs and their attachment to back and belly.

*Removal of Ribs from Inside to Outside Model.*—The ribs should now be taken off the model by inserting a knife between each block and the model, and giving the knife a tap with the hammer. In this way break the glue which holds the blocks and the model together. When all are loose, gradually ("*poco a poco*," as a fiddler would say) press the blocks in turn out of the model, but mind not to loose any of the ribs in doing so. The ribs should at once be placed in the outside model or frame, and have the linings put in them. Take the lining strips and file one edge to a nice round or bevel, whichever you fancy is the prettier, and cut them to fit in between the blocks; make each end which touches either top or bottom blocks a little wedge-shaped, so that when glued and pressed into position they will fit tight; leave them a little "proud" of the ribs.

*Waists.*—When all the eight upper and lower bout linings are in place, sponge all glue off, and attend to the waists. Of course, the linings of these will require to be bent in the opposite direction to those already put in, and may be run into or only just made to fit between the blocks 2 and 3, 5 and 6. If you adopt the latter method, the ribs should, when all linings are fitted, be drawn a ¼ of an inch out of the model, and the linings fastened at each end until set with a cramp (P, Fig. 5). When these are set, press the ribs through the other side of the model, and fix the other two linings. Another way to fix waist linings is to make blocks to fit all over the linings of each waist, and cramp them to the model. Still another way, is to cut a groove in each block with a $\frac{1}{16}$ in. chisel, and run the linings into these grooves. You may use your own discretion as to which method you select. When dry, plane the linings level with the ribs, reduce the top block to ¾ of an inch, the bottom one to ⅞ths, and round the corners off with No. 3 or No. 4 gouge. Next with flat gouge carve remaining blocks level with the linings, giving the inside the guitar shape, and sandpaper all round the insides, using a rubber, to prevent the sharp corners of the gluing edge of the linings being taken off. A great deal of taste may be displayed in lining and in carving the blocks. I have put linings in and carved the blocks in a variety of ways, some of which make the inside of the ribs look very pretty, but these are only "fads," and "utility" is the order of the day.

*Hollowing Back.*—Now give the back a final sandpapering, and then take it off the carving-block by forcing a knife between them from each end; you may now mark the back from inside the ribs. With fiddle cramps fasten the ribs into the position originally traced from the outsides, and mark round the insides with thick lead-pencil; now remove the ribs and replace them in the frame. This done, cut two pieces of deal 5½ in. long by 1 in. by 1¼ in., and glue on them the three pieces of wood, ⅛ in. thick, marked at A, A, A (Fig. 13). Instead of gluing these pieces on, the blocks may be recessed ⅛th of an inch, but the first way is simpler. As soon as your hollowing blocks are ready, lay them on the bench, put the back upon them in the position obviously laid out for it, and through a hole in the bench at each end pass one of the iron cramps, and with a protecting piece of wood, about 2 in. long, on the back, and under each cramp, screw the latter up tight. Next put pieces of cork, 3 in. long, 1 in. wide, and depth to fit under and across each corner; also a small piece under the joint midway of its length. Do not put these pieces in too tight, just sufficiently so to make the back solid. With No. 4 gouge now carefully proceed to hollow, working very steadily, and cutting from inside the pencil mark to the joint. Take only small cuts, constantly trying the thicknesses with the gauge until you have half the back hollowed to $\frac{1}{32}$ in. more than those given in Fig. 14. This is to allow for toothing, scraping, and papering. One side being roughly hollowed, turn the back round, and work the other half in the same way. The thicknesses given in Figs. 14 and 15 are not, of course, absolute; the varying qualities of wood will necessitate slight modifications. The gouging being finished, with tooth plane reduce to a *shade* above the proper thickness, at which you must arrive with the scrapers. *Do not be afraid of using the gauge too frequently.*

*Sandpapering Back, etc.*—After scraping and finally adjusting the thickness, sandpaper all the inside to a good face. The edges may now be rounded. This is done with a round side of a rather fine file, taking off the square edges, and making the entire projection from purfling to rib-line a beautiful roll. Then paper up without destroying the roundness of the edge, wrap it up, and put it out of the way. Do not attempt to do anything with the tab yet.

*Cutting Sound-Holes in Belly.*—The belly, still on the carving-block, will now require fine sandpapering, and the sound-holes to be marked on it. Place the pattern (Fig. 16) parallel with the joint (which will, if all has been carried out as described, be exactly central), with its centre mark, A, 6¼ in. from the bottom of centre joint. Then with a very fine pencil, and with the greatest care, trace inside the pattern. Now reverse the pattern in exactly corresponding position, and mark in the same manner. The circular holes must now be cut out with punches or centre-bits. With the first-named the position is easily determined: press the punch, and at the same time give a circular motion to it. Cut a clean hole—if right through, so much the better; but if you use the centre-bit, take care that you are absolutely central, and do not lay on too hard, or points B, B, will be *shaken* and afterwards *taken* off. You may now follow the pencil line with a knife, cutting in the direction of the arrows. The straight lines, C, C, must be cut from the points. Sound-holes may also be cut out with a fret saw.

*Hollowing Belly.*—The belly should now be taken off the carving-block and hollowed in the way described for the back, or nearly so, as, being different wood, it will require a little different treatment. When you have finished the hollowing, scraping, and papering, the sound-holes may be trimmed with the knife and small files, and the V's cut.

*Fitting Bass-Bar.*—The bass-bar should next be fitted as follows: first plane it down to $\frac{3}{16}$ in., and cut it square off at 10½ in. Now make a pencil line parallel with the joint, but $\frac{5}{16}$ in. distant from it, down the right-hand side, and 1¾ in. from both top and bottom outside edges; make ½ in. marks at right angles with the pencil mark. The position of the bar is now fully marked out. With the flat gouge roughly fit the bar to its place, keeping it perfectly upright. Chalk the bar position well over with a piece of chalk similar to that used for billiard cues, as it is more free from grit than common chalk, and putting the bar close outside the pencil mark, draw it slightly backwards and forwards, pressing gently downwards all the time. With flat oval plane carefully take off the chalk marks which appear on the bar, and repeat the process until the chalk shows all over the fitting edge of the bar, when it

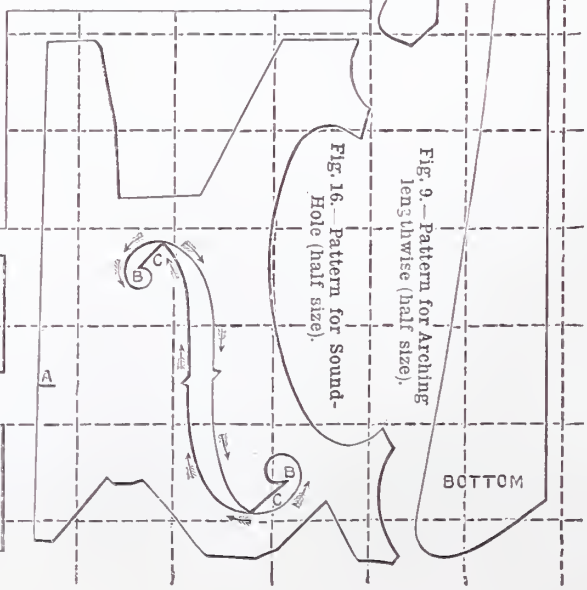

Fig. 16.—Pattern for Sound-Hole (half size).

Fig. 9.—Pattern for Arching lengthwise (half size).

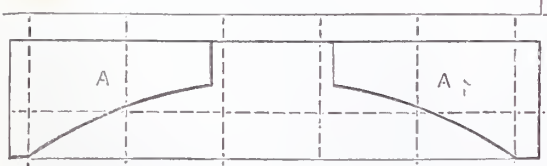

Fig. 13.—Blocks for Hollowing (half size).

will be ready to be glued in. This may take you a few minutes or it may take a long while, but it must be done properly. Now remove all the chalk with a dust-brush, glue the bar, and cramp it in position with the bass-bar cramps (H, Fig. 5). A little fine sawdust should be thrown along the angles formed by the bar and the belly, then with a narrow chisel remove both sawdust and the glue which it will have taken up. When the bar is quite set, plane it down to the right size $\frac{3}{8}$ in. deep at the point where a line between the two inner V's of the sound-holes would cross it, and gradually diminish with a slight curve to $\frac{1}{16}$ in. at each end.

*Rounding Top, etc.*—With rough sandpaper, followed by fine, the top should next be made round.

The edges of the belly should now be made round in the manner described for the back. The sound-holes, when finished, will be rather larger than the pattern, as they have been traced inside a zinc pattern, and it is intended that all the lines should be cut away.

*Gluing Ribs to Back.*—Before fixing the ribs to the back, the blocks should be sized by giving them a good coat of glue, then burning the glue with a hot iron, afterwards rasping off the burnt glue. This effectually stops the blocks from absorbing any more glue. A coat of very thin glue on the rib edges is also beneficial. The ribs may now be glued, placed on the back to the position marked from the outsides, and the end blocks be cramped down with iron cramps, having a piece of wood between cramp and back, to prevent the latter being marked, and also to extend the pressure over the blocks; use the violin cramps all round, and when all are secure, sponge all the glue from inside.

*Gluing on Belly.*—In a few hours you may clean the inside with fine sandpaper, affix your label, and glue the belly on; if any glue should run down the inside, sponge it out directly, as you will not have another chance, but be quick, or the glue will be cold. When the belly is set, remove the cramps, and cut the recess for the bottom nut or rest, over which the tail-band or main-brace passes. With the dividers opened to $\frac{3}{8}$ in., make

a dot close inside the purfling at each side of the centre-joint, and with a knife and small straight-edge cut out the oblong piece of the belly thus described, and fit a piece of ebony $\frac{5}{16}$ in. square into the recess. When set, curve and file the ebony to the same sweep as the belly round it, and at $\frac{1}{4}$ in. from each end curve it down to the belly. The "box" is now made, and begins to look like a fiddle. In my next and last paper on this subject, I shall endeavour to show how the fiddle is finished and strung up.

## ARTISTIC LITHOGRAPHY.

BY MISS ADA J. ABRAHAM.

### Technical Work: Stipples.

First Efforts—Stone for Stippling—Position of Stone—Rest for Hand-Board—Hand-Rest Dots—Taking out Dots—Drawing Tint—Tints in Stars—Flat Tints in Lines—Plates of Tints.

Presuming the student already to have a knowledge of drawing, shading, and colour, he should commence by practising the technical part of lithography, after which we will take him through the different stages, beginning with a simple circular consisting of just a little writing, and proceeding until a finished chromo-lithograph in half a dozen printings is obtained.

Although precisely the same treatment of work is required technically in drawing on stone, whether the subject to be drawn is in colour (chromo-lithography), or merely in black and white (lithography); still, it would be better that the student should keep to black and white in its simplest form, at any rate, until he has mastered the first principles of the art.

There are two ways of working lithographic drawings, namely, stipple and chalk work respectively.

In order to practise stipple work the novice should have a clean polished stone about 12 in. by 20 in., that being a good size for practising, and also a block of wood about 6 in. high, 4 in. wide, and 2 feet long, on which to rest the stone, and so tilt it for convenience in working. (Fig. 1.)

For some work, such as ruling lines, drawing curves, etc., the stone would be better flat, and if a thick pad, made of brown paper, is placed underneath, about the centre of the stone, the artist will find he can turn a comparatively large one in any direction he pleases; but for a drawing he will find the above much more convenient, especially in reaching to the top of big stones, in which case a narrow piece of wood, nailed to the edge of the bench, would prevent the stone from slipping. For very large work, such as posters, etc., there are proper fixtures made, but in these cases the work is necessarily done at the printer's, it being impossible to move such huge stones about with convenience.

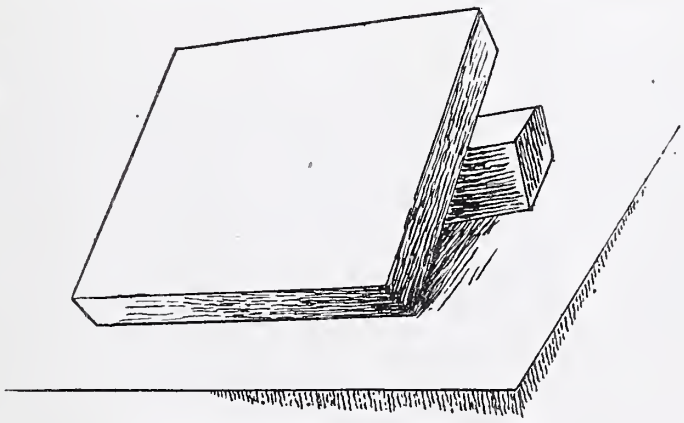

Fig. 1.—Position of Stone on Block and Table.

Gum a strip of mill-board about $\frac{1}{4}$ in. wide down the left and right edges of the stone, on which to rest the hand-board, and prevent it touching the drawing to the detriment of the work, and also gum a piece of white paper along the bottom edge, large enough to cover it, and if this be turned back at the top gradually as required, the stone will be kept covered and free from dust, etc., during the progress of the work.

The hand-rest should consist of a piece of wood about $\frac{1}{4}$ in. thick, 4 or 5 in. wide, and about 2 ft. long, having bevelled edges. A pad is sometimes used in place of it, and can be made of a couple of sheets of brown paper covered with a clean piece of white paper, and on which the pens and chalk can be tried.

Now rule three or four spaces, about 1 or $1\frac{1}{2}$ in. square, with a lead pencil, at the top left-hand corner of the stone, and in the first make an even tint of dots, of any size as long as they are uniform. The student must remember not to work over the blacklead line, or it may prevent fine dots penetrating to the stone, and a white line be the result when printed, especially if a soft lead pencil be used.

Figs. 2, 3, 4, and 5 give examples of different size dots, which it would be as well that the student should copy and get perfect before proceeding any further. He will, perhaps, find that until he obtains full control over the pen, sometimes, against his will, a dot will be made larger than he intended. In such a case leave it until the whole tint is finished, and then cut it in halves by means of the steel pointer, or else place the pointer in the centre of the dot, and by giving it a sudden twist round a slight hole will be made in the stone.

In taking out lines or dots, the stone must be scratched, it not being sufficient only to remove the ink; for, although not perceptible, it may still roll up in printing. The ink having once touched the stone, adheres so strongly to it that it cannot be removed without scraping away some of the stone at the same time, and although the part thus scraped will appear white in comparison to the surrounding stone, it does not affect the work when printed.

To draw tints like Figs. 2, 3, 4, and 5, make a dot, and use it as the centre of a star, then make about five dots round it, and so continually make it larger by placing each successive dot exactly between two other dots, and exactly the same distance apart. Thus, if the dots are of uniform size, the tint will be perfectly even; if too much space appears in any portion of the tint between the dots, it

Fig. 7.

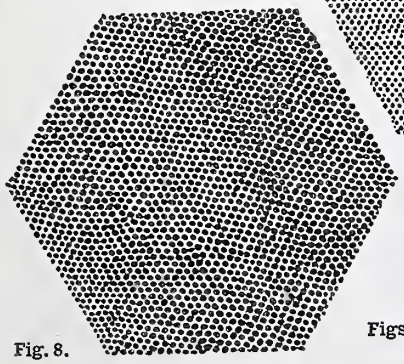

Fig. 8.

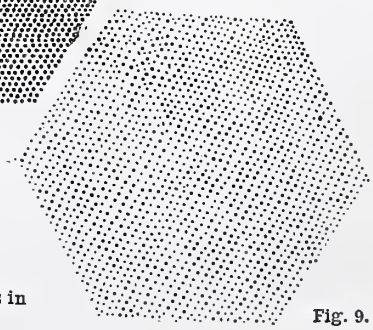

Fig. 9.

Figs. 7, 8, 9.—Tints in Dotted Line.

may be rectified by filling it with finer dots placed between the others, which would not materially affect the tint when finished, if carefully executed.

At starting, the novice will find that the dots, instead of appearing round, will look like triangles; this is because the pen has been dragged unconsciously along the stone, and perhaps only worked on one nib. The pen should be worked on both nibs and held nearly upright, so as to work on the point; it must be placed firmly on the stone, and lifted from it in exactly the same place. The longer the pen is allowed to remain on the stone the larger the dots will become. Fig. 6 is a specimen of uneven tinting and bad dots.

Unless the pen is cleaned frequently the ink will dry in it and get clogged, the substance of it being so much thicker than the ordinary writing fluid.

It is necessary to make a perfectly black dot on the stone, or the acid will eat through the ink quicker in those parts where it is weak.

Figs. 2 to 6 are examples of working different tints in stars, and Figs. 7, 8, and 9 show specimens of tinting where the dots are worked in lines. The student will soon observe by experience how closely one line should be placed to another, and the various sizes the dots should be made for different kinds of work.

In making a flat tint in dotted lines, the same as in stars, the dots must be placed between, and not underneath, each other to obtain an even tint, which at present is the student's ambition, and he should well understand that it is better not to depend on rectifying any mistakes in his work by means of scratching with the needle, or filling in with dots, as he would be likely to get into a careless way of working, and be very disappointed when his work was printed. If the tint is not progressing satisfactorily, the student must not get out of patience with his work, as that would only make matters worse, but try another pen or clean the one in hand, see that the ink has not got too thick, rule another square, and try again; and if he takes to heart that the cleaner the stone is kept, the blacker the ink is, and the rounder, firmer, and more uniform the dots are, the more even his tint will be, the clearer it will print, and the more satisfactory his work will eventually turn out.

Of course, there are times when it is not necessary to be so particular over a tint, but if the artist can do the best and finest work he can easily do the other; but on the other hand, if only able to do the common class of work, he will find himself at a great loss when wishing to undertake a better style.

Steel plates are made consisting of dots, lines, curved lines, curved dotted lines, etc., etc., which can be transferred to stone by gumming over the parts not required for the tint, and then placing a transfer from the plate upon it, the gum preserving the stone where no tinting is required. This saves the artist a great deal of trouble in large, flat tinting, but is principally used for colour work.

Having now become familiar with the use of the pen and gained full control over the same, the student should next attempt a shaded tint by means of dots of various sizes.

## A PORTABLE FOLDING WARDROBE.

BY B. A. BAXTER.

A Receptacle for Clothes — Light Framed Back—Framed Ends Hinged to the Back —Top to Fall over the Folded Ends when Closed, to Rest upon Ends when in Use—Preparation for a Curtain to form Front.

There may be many readers of Work who are longing to use their newly-found skill, and to make some article of utility. The difficulty is, often, in deciding what is within their capability. They would like to make the very excellent and ingenious combination bedroom suite by Mr. James Scott, in Vol. I., pp. 401-2, but that is, without doubt, a difficult task for an amateur. I recently made a portable receptacle for ladies' dresses, etc., for a customer, who suggested the plan, which, having somewhat improved, I submit to the notice of my fellow-readers. This portable wardrobe is shown complete and open in Fig. 5. The top is a piece of 1 in. deal, about 3 ft. 6 in. long and about 20 in. wide, but any suitable dimensions may be adopted, providing only the length is somewhat in excess of twice the breadth, for reasons which I will explain presently.

The back is a frame halved or mortised and tenoned together, about 2 in. narrower than the length of top. The stuff of which it is made may be 3 in. by 1 in. The height is variable, and depends on the length of the garments it is desired to put into the wardrobe; 5 ft. 3 in. or so would do, but in this also be guided by any lady who has a right to advise in the matter.

Having, then, a frame for the back of the dimensions deemed suitable, pieces of 1 in. wood should be fixed on to the face of the frame at the edges, as in Fig. 1, which is shown in plan.

This is to give room for the hooks. The ends are similarly constructed, and should be each alike, one-half of the width of the back frame in width, and the same height. These ends are hinged on to the pieces fixed on the back, so that the whole will close, as shown in Fig. 2; and when some brass hooks are affixed to rails screwed on to both back and ends, there will be room, with care, for the hooks, without any coming into collision. It would greatly assist in avoiding this if the hooks at the back were fixed at a different height to those on the ends.

Having made the three frames, and hinged them together, the top—a piece of 1 in. deal—should be hinged to a piece fixed on to the two pieces which serve to hinge the sides. If the maker chooses, preparation could be made for a more workmanlike and strong fixture by mortise or dovetail; of course, this would involve cutting the hingeing styles a trifle longer. It is necessary to observe that the width of the top hingeing piece is such that the piece which forms the top can fall down freely in front of the closed ends. A ledge fixed on under side of top at ends would form a suitable stop, and a rod cut to the length of the space between ends when open would keep the whole thing open to the proper distance.

This rod can be supported by two pieces of 1 in. hard wood, having a centre-bit hole of the proper size. One of the pieces must have the hole cut into, as in Fig. 3. On the rod a curtain can be hung; the back and end frames may be covered with a suitable cretonne, or covered with canvas and wall-paper to match the room in which it is to stand.

I ought to say that either "butts" or "back flaps" will do for the ends; for the top, however, the hinges should be let in so that the hinge does not project at all, for that would be in the way of the ends. Probably the best way is to use butts, as in Fig. 4. The part blacked must be planed off to the proper depth before fixing the hinges.

I can only hope that I have explained this simple construction with sufficient clearness, and that all who attempt may be successful. It will, I believe, keep the clothes from much dust, and will relieve the pressure upon the hooks of bedroom doors, where clothes hanging are in the way, and are both inconvenient and unsightly. Moreover, the weight thus thrown on the upper part of the door tends to exert a strain on the topmost hinge, which is undesirable. It may be added that as the wardrobe is both folding and portable, it could be taken to the seaside by visitors for any lengthened period to supply the want that is often felt in lodging-houses of a receptacle for clothing in addition to the ordinary equipment of the bedroom.

Fig. 5.—Portable Folding Wardrobe, shown complete and open.

## ITALIAN DESIGNS FOR FRET-WORKERS.

BY I. N. TARSIA.

ARTISTIC TREATMENT AND STYLE—MARQUETRY—XYLONITE — SUBJECTS OF DESIGN — MILAN CATHEDRAL DESIGN—MINIATURES.

ENGLISH, American, and German designs are known to all fretworkers in this country, and without any desire to disparage them, or to deny the excellence of many of them, the knowledge that a large series of Italian origin may be had will be welcome to those who wish for some variety. There are, no doubt, several collections of designs published in Italy, but, so far as I know, there is only one of them which is obtainable in this country, and the designs of which it consists are not so well known as they deserve to be. As I conceive it to be the duty of readers of WORK to proclaim for the benefit of their fellow-readers anything that may be of interest, I have pleasure in writing these notes.

That the artistic merits of these Italian designs, which, so far as I am aware, are only obtainable from Mr. Busschotts, Park Lane, Liverpool, are far superior to the average English and American productions, will be easily understood. They are, indeed, the work of artists, and bear, perhaps, a closer resemblance to the French than any others with which I am acquainted in delicacy of treatment. They, however, form a class by themselves, and it is only natural to find that many of them are in the style of the beautiful Italian Renaissance. Those readers who are acquainted with this will easily understand that a successful rendering of this in fret requires some very fine work, such as will tax the skill of the most accomplished sawyer. There are, however, many designs which, while equally beautiful, are of a simpler character, but speaking of them as a whole, anyone who can cut the designs nicely will find no other fret patterns beyond his capacity. For overlays or inlays most of the designs are well adapted; while those who possess some skill in colouring, or adapting colours, will have no difficulty in working them up as elaborate marquetries.

Ivorine, or xylonite, has been recently referred to in WORK, and I may say that it is a very good material in which to work up even the finest of these Italian designs as inlays, and much easier than veneers or thin woods.

In the collection are found the usual articles which are mostly made up in fretwork, such as boxes of various kinds, brackets, etc., etc.; and there is one specially noteworthy design, or rather series of sheets, for the formation of a model of Milan Cathedral. This wonderful article in fretwork, which, by the way, I understand, has lately been completed by one of Mr. Busschotts's customers, contains no fewer than 3,621 pieces, measures 6 ft. in length by 3 ft. in width, and stands 4 ft. 6 in high. It is quite the largest and most important design ever attempted in fretwork. Perhaps someone will get up the "Milan Cathedral" for a future WORK Exhibition. The designs themselves are printed in solid blue, and the various parts of the articles represented are shown in the clearest way.

I do not think Mr. Busschotts has catalogues showing the miniature designs, at least I have never seen any, as my usual plan has been to call in and make a selection from the sheets themselves whenever I have been in his neighbourhood. I understood lately, when speaking to him on this subject, that he intends to have sheets of miniature designs; so possibly by the time these remarks meet the reader's eye they may be ready. With this, however, I have nothing to do, and, having drawn the attention of those who wish for designs quite distinct from those usually seen, I must leave them to take care of themselves. As I have many of the Italian designs, I shall be happy to answer inquiries respecting them in "Shop."

## MEANS, MODES, AND METHODS.

### A SIMPLE AMBULANCE.

SOME of the readers of WORK may have invalid relations or friends that have to be carried from room to room. My wife has been obliged to lie prostrate for the last ten months, and having to be carried, set me to work to devise a simple ambulance, which has answered so well that I think it may be useful to others. I went to the upholsterer's, and bought two 6 ft. lengths of common cornice-pole (2 in.), for which I paid 2s., but any similar pieces of wood will do if nicely rounded. I then went to the linendraper's, and got 4 yards of strong unbleached calico, 30 in. wide; and with this made two bag-like cases, 32 in. deep by about 2 ft. wide. These are passed under the patient, one under the legs first, and the other under the body. This can be better done than if the sheet was all in one piece. The two poles being then passed through the sides of the bag, forms a simple and safe hand-barrow. Of course many will ask, where is the difference between this and a stretcher? I claim, first, the simple form, and attach great importance to it being in *two pieces*, as the use of it will soon prove. Then, why is it necessary to have a bag-like arrangement, and why not two cases for the poles? First, I say it is stronger for the same kind of cloth; and then, being without seams, it is smoother to lie on. The width should be according to the size of the patient; but I found it a mistake to have it too wide, as the patient sank down in a most uncomfortable manner; 20 in. to 26 in. will be enough for any person. Then the cost—only 3s. or 4s.—is something.

I have spoken of this simple ambulance as being suitable for home use, but I am inclined to think that it is equally well fitted for general use, and that in cases of illness or accident in the street it would prove far more desirable for the sufferer than the ordinary stretcher.

## PHOTOGRAPHIC TENTS.

BY AN OLD HAND.

INTRODUCTION—MEANS OF CONVEYANCE—VARIOUS TENTS AND CHANGING BOXES—COVERING—FITTING—LIGHTING—VENTILATING—PACKING.

FORMERLY a photographic tent was as much a necessity as a camera, but with the advent of dry plates, most of the chemical manipulations required to make the negatives have been conducted at home, where a suitable room could be prepared for development and the prolonged washing requisite under the new order of things. The few minutes' washing formerly required has changed now to so many hours, and the development much simplified. Plates can now be kept months after exposure, and developed at leisure. The fact of immediate development being unnecessary, without entailing any deterioration of the results, has induced a general practice of bringing home the exposed plates; thus avoiding the incumbrances of tent and chemicals being taken on tour as a necessary part and parcel of the photographic kit.

The outdoor photographer of the present day has no idea of the number of bulky and weighty articles his less fortunate predecessor of years ago had to put together and convey with him if only two or three negatives were required. I use the word "convey" advisedly, as carrying was quite out of the question, unless one or two other persons were pressed into the service; even then it was somewhat a toil of a pleasure. If going single-handed, a truck, or wheels in some form or another, were generally used. Professional photographers on the warpath often had a single horse carriage fitted as a laboratory, which was, perhaps, the most convenient tent of any, and the working conditions rendered similar to those at home no small advantage, when taking a good negative was always an extremely critical and careful operation under any circumstances, and a good, clean, brilliant and soft negative was something to be proud of. Tents are, however, even now sometimes required. It may be necessary to finish a negative off on the spot, so to say, to test an exposure, or for some other reason; and although an absolutely dark closet and a small table are all that are required in the way of an operating chamber, these are not always available nor convenient. A tent will then be found to tide over the difficulty, as it can be set up anywhere indoors or out of doors, and make the photographer independent of any concession, either graciously or grudgingly given. Some people have a great objection to their furniture and fittings being splashed and stained, and do not go into ecstasies when a brown patch gradually develops on the drawing-room ceiling. A tent set up out of doors, or in an outhouse by preference, avoids a considerable amount of friction with the household powers that be, and conduces to general good feeling all round.

In this and a paper to follow I propose to select a few of the most useful forms of tents and changing boxes, with illustrative diagrams that will enable anyone with a small amount of constructive ability to make one for themselves. The variety of forms of tents are legion. Two or three points in all forms should never be overlooked. These are plenty of room to work in, good ventilation, and convenience of arrangement. Tents may be roughly classed into three species—first, those that are portable laboratories, in which work can be as easily done as in a properly appointed dark room at home; secondly, tents that can be used for development, but more generally for changing the plates or fitting the slides; thirdly, those for changing the plates only, that may either admit the operator to work inside or to remain outside with his hands passed through sleeves, and either watch the operation through a small ruby glass window with a face piece, or trust entirely to feel.

No. 1 represents the most elaborate, or I should rather say convenient, of the tent tribe, being, indeed, a perfect laboratory of its kind, and in which almost any sized plates in general use can be conveniently manipulated. It consists of a tray made watertight, 36 in. long by 18 in. wide, and 4 in. deep, made of ⅜ in. pine, and clamped at the corners—in fact, made strong and serviceable as a packing-case, for which it has to do duty.

Inside this tray, at each corner, is fixed a square iron socket to hold the uprights that form the framework of the tent. A hole is pierced through one corner for a rubber tube to carry away waste water. Centrally another hole is made, strengthened with a brass plate for a bolt to attach it to its support, which may either be a very strong tripod or, much better, the box in which the chemicals, etc., are packed. A narrow detachable shelf is fitted to the side away from the operator for bottles, measures, etc. The frame consists of ¾ in. square rods. Two pairs are hinged together, as in diagram; the two back uprights and two cross-pieces are separate. The front uprights are 3 in. shorter than the back ones, so that, when fitted in place, the roof will slope upwards towards the back, giving more head room than if they were on a level; the longest pieces, which are the two back uprights, are just the length to lie in the tray for packing. The cross-pieces which bind the sides together are provided with pins, with beads fitting into slots on the inside sides of the uprights. The whole is then covered with a suitably-shaped bag made of three thicknesses of twill, and bound, the inner ones being respectively red and yellow, and the outside drab or black. By cutting away the outside layer for a space of 12 in. by 8 in. in the front of the cover, just above the tray, a window is formed; or, if preferred, an opening can be made through all the material, and a light wooden frame screwed to it, in which ruby glass can be slipped for those who prefer this mode of illumination. An extra curtain of yellow or red may be placed inside and hooked up out of the way when the light will permit. Several hooks and pockets are made inside to contain dusting-brush and other little useful items that are to be kept dry and clean. A strap inside the cover, made of 3 in. webbing, attached to the front and two sides, fastens round the tray with a buckle, keeping it taut and light-proof. On the left side a bag is attached to the cover, hanging outside the tray and opening inside, to contain a vertical hypo. fixing-bath, thus economising the room and putting a troublesome solution as much out of the way as possible. The back part of the cover is made on the cross-over principle, and the operator, on taking his place inside, hooks a strap attached to this cover round his waist (as he sits on a camp-stool), which effectually excludes all white light, and leaves a roomy, comfortable space to work in. The length of the cover is such that, when set up, it will fall an inch or two on the ground—an extra precaution against the admission of dangerous light. On coming out of the tent the folds of the cover can be thrown back, and thus thoroughly rid the tent of any disagreeable fumes from ammonia or anything else. For ventilation, a sleeve or a box ventilator can be let in. The sleeve ventilator is a tube of twill about 4 in. in diameter and 1 ft. long, that when in use is filled loosely with hay, grass, etc., or anything of the kind that may be available to allow passage of air without light, and lie on the roof of the tent. The box ventilator (Fig. 2) consists of a ring of metal—tin will do—3 in. or 4 in. in diameter and about 1 in. wide, securely fastened into an opening in the roof of the tent, into which is brought another metal cylinder with diaphragms alternately fastened to each side to act as a light trap and not interfere with the passage of the air; a bit of muslin may be fastened over the top to keep out dust. This ventilator is suitable for any tent that may require one. It will be seen from the diagram of the tent that the rods of the side frame project over, or rather beyond, the head of the operator for the sake of gaining room and air space.

A shallow waterproof wooden tray 18 in. long, 15 in. wide, and 2 in. deep, with an indiarubber tube securely fastened in one corner, and which can be passed through the tent tray, acts as a sink and also to pack in developing dishes, etc., in travelling. To pack, remove the cover, take the frame to pieces, laying them in the tray, fold up the cover, lay it at the top, and pull over all a canvas waterproof cover, and strap together. This, although a heavy tent, is, nevertheless, a most useful one, never gets out of order in any way that cannot be easily repaired, and is thoroughly efficient for any photographic purpose.

## WIRE-WORK IN ALL ITS BRANCHES.

BY JAMES SCOTT.

Straightening, Soldering, Galvanising, Tinning Brass and Copper Wire, Lacquering, etc.—The Swift.

There have been several diagrams given in past numbers of Work, by several correspondents, illustrating the numerous methods adopted by different men to straighten wire as it is uncoiled, or when in irregular lengths; but I do not see any reason why I ought to refer my readers to any or all of them, although the results of using either method would lead to the desired result—in fact, my series of papers dealing with wire-work would be incomplete were I not to say something about this part.

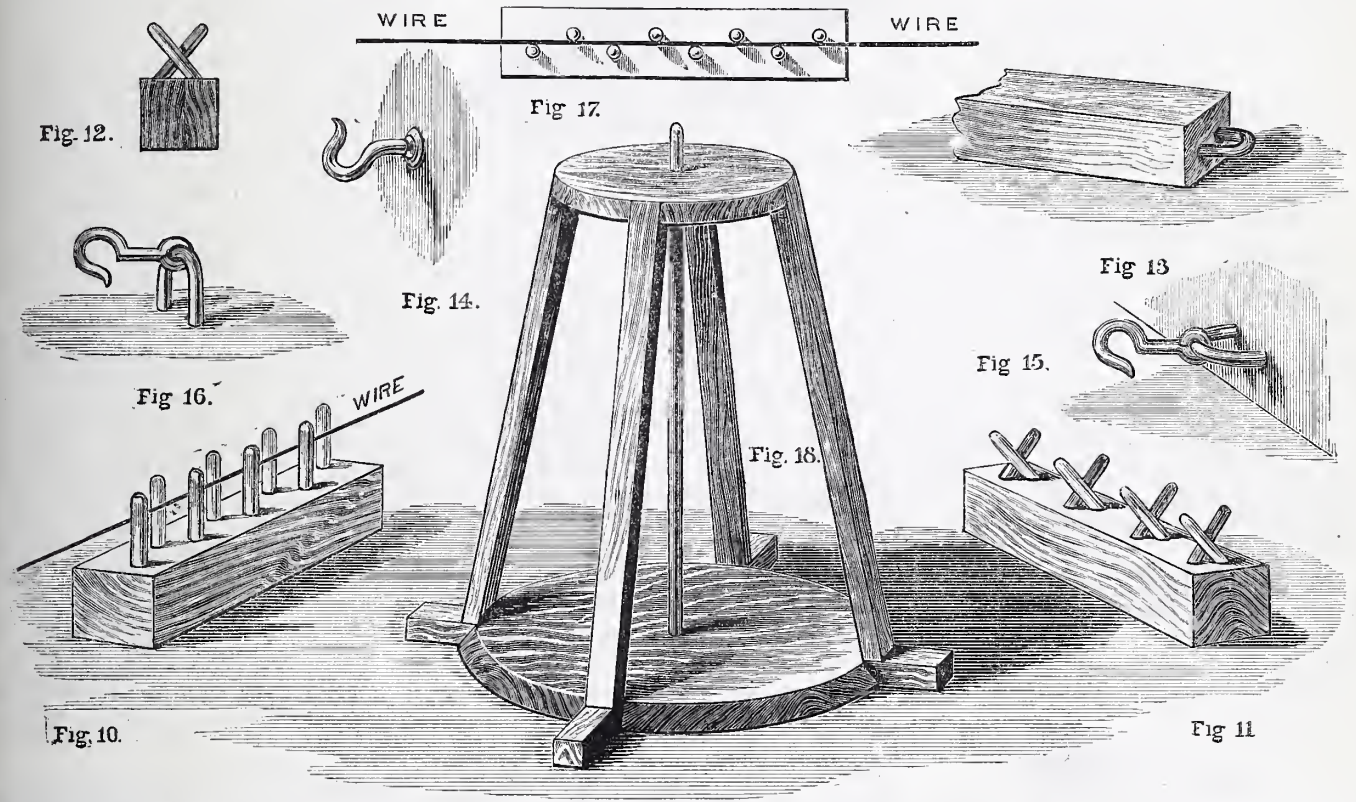
I understand that what is considered a good means of straightening wire is that which I have drawn in Fig. 10. There is a wooden block of three or four inches depth, and of a similar width, and in length what might be considered preferable, into which are inserted at the top a number of iron or steel pegs or nails; the second, fourth, sixth, etc., peg being very slightly to one side of an imaginary straight line, upon the other side of which is similarly situated the first, third, fifth, etc., pegs.

The wire is drawn between these pegs, entering them at one end of the block, and being pulled out at the other end of it. It is advisable to have different blocks and pegs for every few consecutive gauges of wire; but for any of those which do not vary much in thickness to each other, the same block, etc., would serve, as the pegs could then be slightly hammered inwards or outwards, as the case might be, to accommodate properly the wire to be straightened.

If the pegs are so fixed that each row inclines towards the other at a very acute angle, as in Fig. 11, both pegs in each pair touching and crossing each other, as is made plain by the elevation sketch (Fig. 12), very irregular lengths of wire may be comparatively well straightened by being drawn through the holes or arches formed by the different pairs of pegs.

If it is not considered convenient to have the block as a fixture upon the bench, it could be used as a loose affair, and be secured in temporary position when required, by being fitted with a staple at one end, as I have shown in Fig. 13, and having a hook, or staple and hook, in the wall or bench, as in either of the diagrams, Figs. 14, 15, and 16.

As before said, the ways of effecting the straightening of wire are numerous; but these descriptions will be found suitable and convenient.



**Figs. 10, 11.—Two Forms of Straightening Machines. Fig. 12.—End Elevation of Machine shown in Fig. 11. Fig. 13.—A necessary Staple in End of Straightening Block. Figs. 14, 15, 16.—Various Means of securing Straightening Block to Bench or Wall. Fig. 17.—Plan of Fig. 10 as seen from above. Fig. 18.—The "Swift," on which Coils of Wire are placed previous to being unwound.**

Although the word "lacquering" is used frequently in connection with several operations in different trades, in wire-working it is understood to mean the covering of *brass* wire for purposes of preservation with a certain semi-liquid. No doubt many readers are aware that lacquer is very similar in appearance to fluid gum, and is dealt with, like that commodity, by being contained within bottles. There is a paper on "Lacquering Brass Work" in Work, Vol. II., No. 55, page 35. I will ask my readers to be good enough to read the particulars therein given—they, in every respect, being quite suitable for application to wire-work.

Galvanising is a very important process, through which an enormous number of wire-work articles pass. I cannot explain the operations having to be gone through for this purpose, for the simple reason that I am entirely ignorant of anything whatever concerning them directly; and, indeed, I see no more reason why I should enter into a description, even were it in my power to do so, than should a writer who gives a design of a piece of furniture, or who speaks of wood-work, enter into details of the art of polishing.

Wire-workers—*i.e.*, the workmen—do not galvanise their goods: they are sent to be so finished at a neighbouring galvaniser's; for such a trade is carried on as quite distinct from wire-work. The same remarks will apply equally to the process of tinning.

Need I say much about painting? What workman is there who could not paint any piece of wire-work to his satisfaction with either enamel or the ordinary stuff? Of course, the article to be painted would have to be entirely free from dirt, etc.; but very few men, I think, need to be told that.

Brass and copper wire, it scarcely needs telling, are more expensive than ordinary wire; and both are, as a consequence, used almost exclusively for ornamental work, such as baskets, screens, etc. Occasionally, however, such articles as fenders and other household requisites are constructed with it.

Soldering is an operation that frequently has to be called to the aid of wire-work, but comparatively few different articles need its assistance. For details of the process, I must refer my readers to Mr. Alexander's paper on "Soldering" in Vol. I., page 257.

The "swift" is an accessory to wire-working, upon which is placed a coil of wire preparatory to being straightened or crimped. A clear idea of its appearance can be gleaned from Fig. 18. In the bench is firmly inserted, in a perfectly perpendicular position, a stout iron or steel rod, upon which will revolve the swift proper. This latter consists, as can be seen by the engraving, of two circular boards, one much smaller than the other, with canted or bevelled edges, connected to each other by three or more uprights.

Each board has a hole bored through its centre, sufficiently large to permit of free action on the part of the swift whilst upon the vertical rod. The larger board rests upon the bench, while the smaller one is placed at a convenient height from it, both being strongly connected to each other by three, four, or more, wooden or metal rails. It is not desirable, however, to have it of any inconvenient weight.

The inside diameter of one coil of wire may happen to be less than that of other coils, and it is to accommodate all dimensions that the swift is made on a graduated scale; for it will be seen that should one coil be too small to fit round the bottom of the swift, it will rest in just as suitable a position upon the sloping rails. If the swift is properly made, it should be all that is required to assist in unwinding any particular coil.

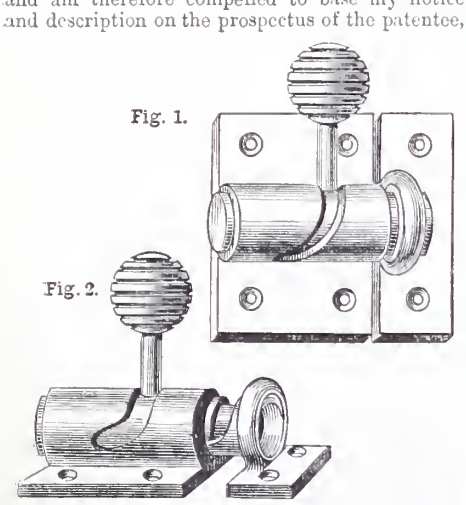
It is advisable that two swifts be used—one much smaller than the other, in order that it can be used for very small coils.

## OUR GUIDE TO GOOD THINGS.

**** Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

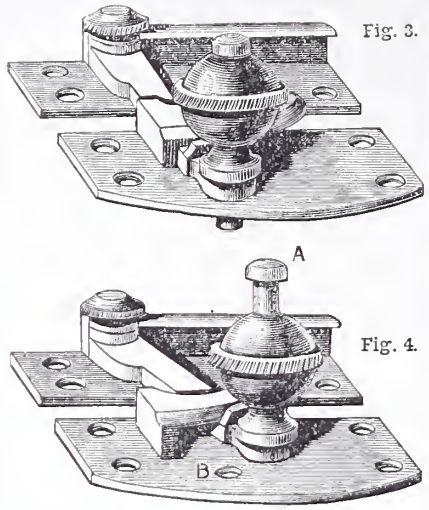
### 19.—Cormell's Patent Grip Fastener.

A fastener for doors and windows that is perfectly secure against all operations from without—operations, that is to say, which may be carried out without injury to glass and frame of window and rails and panel of door—is manifestly a thing to be sought after; and any fastener that cannot be operated on from without, except by violent means, is decidedly a "good thing." Apparently, Cormell's Patent Grip Fastener is a fastener that promises security to those who adopt it—I say apparently, because I have not had an opportunity of seeing and handling a specimen fastener, and am therefore compelled to base my notice and description on the prospectus of the patentee,



Cormell's Patent Grip Fastener.

Mr. J. Cormell, Lansdown, Cheltenham. The appearance and general construction of the Patent Grip Fastener may be gathered from Figs. 1 and 2, in the former of which it is represented shut, and in the latter, open. There are two plates to be fastened to the door and frame of the door, or to the sashes of the window to which it is applied. The larger plate carries the bolt, and the smaller plate the socket, staple, or ring in which the bolt engages. The description tells us that "the holt is moved by the action of the arm, which moves it in the barrel," and that the *female* screw on the end of tho bolt grips the *male* screw in the staple, thereby tightening the sashes together, if loose, and avoiding rattling



Brookfield & Whitehead's Burglar Proof Sash Fastener.

and securely fastening them. Now here comes in the disadvantage of not actually seeing the article to be noticed. I should have thought myself that the screw on the end of the bolt would have been the *male* screw, and that in tho staple the *female* screw; but, in determining this, the drawings in tho prospectus, which are here reproduced on a smaller scale in facsimile in Figs. 1 and 2, lend but little assistance. Still, there is enough to show that the fastener is a secure one, and is worth looking after, as it is simple, has no spring in it, is thief proof, prevents loose frames from rattling, and is cheap, as it is supplied at the rate of 7s. 6d. per dozen in the ordinary make. For high windows tho bolt is made without the knob on the arm, as shown in Figs. 1 and 2, and is actuated by a wheel fixed at the end most remote from the socket. Over the wheel a cord is passed, the groove of the wheel in which the cord lies being fashioned in such a manner as to prevent the cord slipping. The cord may be fastened up on one side of the window in the same manner as the cord of a Venetian blind.

### 20.—Brookfield & Whitehead's Improved Sash Fastener.

The construction of tho fastener for doors and windows just described differs materially from that of the ordinary fastener; but this is not the case with regard to Messrs. Brookfield and Whitehead's Improved Sash Fastener, which is represented, when shut, in Fig. 3, and when open, in Fig. 4. At first sight, indeed, one may be disposed to ask in what particular point or points this may differ from the ordinary sash fastener, so much alike are they, and it requires close inspection to find out that these differences are to be found in the increased size of the plate which carries the piece, under which tho catch passes, and in the knob of the catch which is pierced from top to bottom to take a pin, A, in Fig. 4, which works up and down in it. When the catch is released, the bottom of the pin moves over the surface of the plate, and the pin is kept in the position shown in Fig. 4; but when the catch is brought completely under the piece that projects from the plate that is fastened to the lower sash, the pin drops into the hole, B, and assumes the position shown in Fig. 3, thus closing the window and securing it against all attempts that may be made to open it from without. When it is desired to release the catch, the pin must be lifted. This fastener, which is extremely simple, and has no spring to get out of order, is manufactured and supplied wholesale by Messrs. Brookfield & Whitehead, 25, Change Alley, Sheffield, who are the makers of other desirable specialities. Its cost is no more than that of the ordinary fastener, and it may be had in brass, or japanned or nickel-plated, of all large ironmongers and builders' furnishers in town and country.

I have purposely noticed this and the Patent Grip Fastener together, as each is a type of a totally different mode of fastening a sash-window. Each, without doubt, will have its admirers, being considerably in advance in every respect of the ordinary fastener, which is so easily thrust back from outside by the aid of a thin steel knife.

### 21.—The "Ring" Cushion Tyre.

The "Ring" Cushion Tyre is one among the various forms of tyres of this kind that are now competing for favour and adoption by wheelmen. The nature of the tyre, and the arrangement of the rings from which it takes its name, may be gathered from Fig. 5. The inner and outer metal tyres of the kind in general use by the trade are separately drilled to receive studs which secure the ruhber rings in position between the two tyres. The rings are moulded to fit *over* the outer tyre and inside the inner crescent, and their strength is regulated to suit various weights. The spokes of the wheel, in case of necessity, may be replaced without disturbing any portion of the tyres. The objects of this invention are stated to be—1st, to maintain at the point of contact with the road a true circle in the outer tyre; 2nd, to avoid the cutting of the cushion; 3rd, to promote economy of cost, about one-half the weight of rubber being used, inclusive of the outer tyre; 4th, to provide a cushion tyre for narrow forks, which may be easily fitted to existing machines. It is claimed by the patentee that the use of the tyre ensures all the benefits to be derived from the pneumatic tyre, inasmuch as "the shape and position of the rubber rings ensure the most sensitive and perfect action in running. Every ring is in continual play; in the lower portion of the wheel they are in extension; at the sides of the wheel a vertical movement takes place. The double, and hitherto impossible, duty of resisting hard road wear, and, at the same time, of yielding that ease and elasticity essential to the comfort of the rider, is by this arrangement separately provided for. The sole duty of the rubber rings is to carry the weight of the rider in easy suspension, whilst the outer tyre, narrow in width and fairly hard in texture, is propelled with less exertion than the wide soft tyres which flatten upon the ground and add materially to the draught of the wheel. The greatest ease in running, with perfect insulation from vibration, is thereby obtained, the rubber rings acting freely upon the road inequalities, and within one inch of its surface. In turning corners they adapt themselves to the deflection

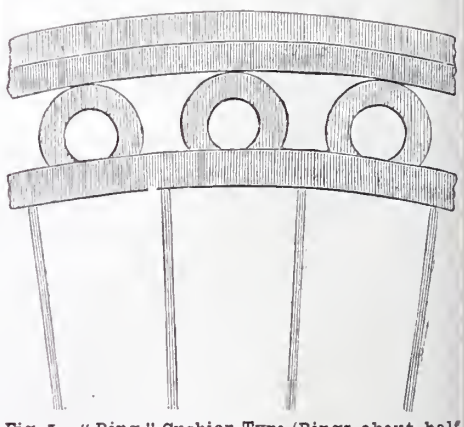


Fig. 5.—"Ring" Cushion Tyre (Rings about half size).

of the rider's weight, and obviate the tendency to side slipping. Travelling against the wind, the resistance would not be greater than with an ordinary solid tyre." The "Ring" Cushion Tyre is applicable for vehicles of all kinds. Complete wheels, tyres, or any of the necessary parts may be obtained at 19, Barbican, London, E.C., the London Depôt of Messrs. Thos. Smith and Son, Saltley.

THE EDITOR.

## SHOP:

### A Corner for Those who Want to Talk It.

*** *In consequence of the great pressure upon the "Shop" columns of* Work, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* Work *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### I.—Letters from Correspondents.

**Work Exhibition.** — W. C. (*Shrewsbury*) writes:—"I beg to offer you my heartiest thanks for the medal, prize, and certificates awarded to me in Work Exhibition, and which I have safely received. I should have acknowledged their receipt sooner had I not been very fully employed in moving from Birmingham to Shrewsbury, and taking up another situation. I am glad to believe that my success in Work Exhibition may have been a determining factor in obtaining for me the situation above mentioned, in which I benefit to the extent of £60 per annum. The award of the jurors came at the very time I was making my application; and I, of course, made mention of the fact of my success. Though I have no direct authority for stating that I owe my better situation to my Work award, I feel confident it had its share (and probably a large one) in obtaining my appointment in the face of over 300 competitors. I am delighted with the medal, which is a little work of art, and also with the prize and certificates, which I shall always be proud to show to my friends."

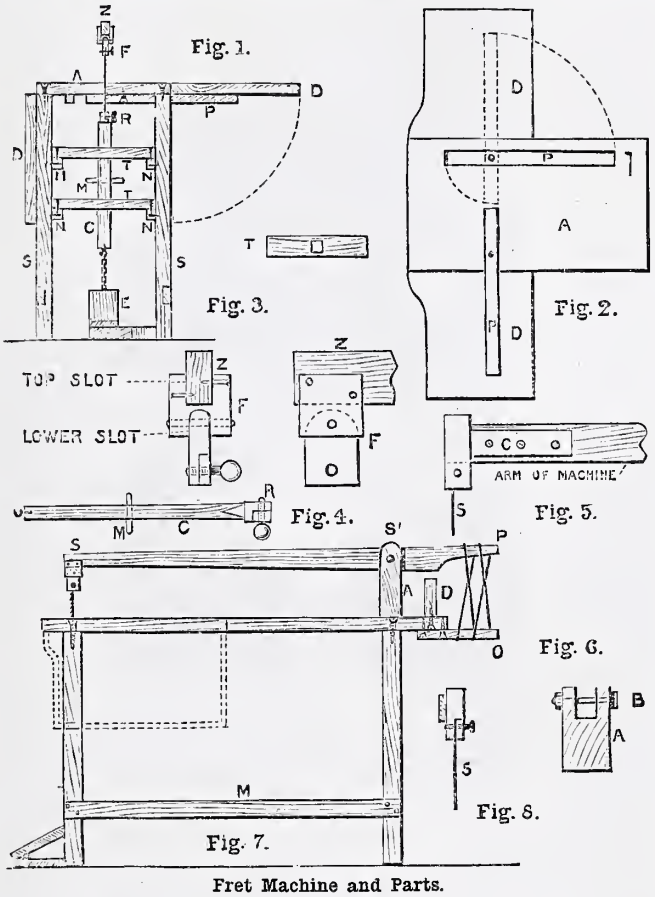
**Protection for Patents.**—A. J. W. writes:—"I have duly received medal and awards safely, and must say that I am very well pleased with them, and thank Messrs. Cassell & Company for their kindness and enterprise in the prizes and awards given, and labours in connection with the late Exhibition—which could not have been an altogether simple matter from first to last. At any future time, should you think of inaugurating another exhibition, I shall be only too pleased to do all that lies in my power to give assistance, however small it may be, in exhibiting to the best of my ability. Last month a provisional protection was granted me for a patent banjo, in the taking out of which I was much assisted by your article which appeared in Work; and hope in another month's time to procure a complete patent for same without the expense of an agent. I may add that the drawings I sent in to minimise labour were incomplete."

**Work Exhibition Certificate Frame.**—W. J. (*Laurencekirk*) writes:—"Now that the exhibitors at the Work Exhibition are in possession of their certificates, I have no doubt that many, like myself, wish to frame them; and for those who use the carving tools an appropriate design given in Work would be hailed with delight by not a few."—[Will some reader kindly consider this?—Ed.]

### II.—Questions Answered by Editor and Staff.

**Cutting Elephant Teeth.**—J. S. S. B. (*Dublin*).—I presume from your letter that it is your idea to make elephant's grinders into boxes. If that is so, then all your difficulty will vanish if you once know how to get through, or get rid of the external layer of enamel. It will really be best to get a lapidary to cut the teeth across with his slitter, but the following is a way that you can do yourself:—Get some iron binding-wire about the thickness of a pin, and twist two pieces up together like a cord, say about 2 ft. long; mix up some flour emery with water and charge this twisted wire with it. Now, for the next step, you must devise means yourself to attain this end—viz., that the tooth has got to have the wire passed backwards and forwards like a saw until you have worked through the enamel. Fixing it in one of your bow saw frames will do, or you might fix one end of the wire and hold the other with your hand while you pass the tooth rapidly up and down. As the wire is merely for the purpose of holding the emery, it can be replaced by a straight piece of hooping-iron, and you can get through the enamel with that; but, as I said, a lapidary's slicer which is charged with diamond dust is best. So much for cutting pieces off; now, if the outside (enamel) is to be got off so that you can carve the exterior, the handiest method for you is, I should think, to take it to the grindstone and grind it off. If these hints are of no use, you have only yourself to thank, for no details are given in your letter.—H. S. G.

**Fret Machine.**—G. G. (*Abergavenny*), requires further particulars concerning my fret machine (see page 846, Vol. II.). I feel it a pleasure to answer the above from one who, I think, sees the advantages of this machine—firstly, its simplicity; secondly, its having a true vertical stroke; thirdly, its lowness of price for construction. I will now endeavour to give him and others all the particulars so far as my ability will allow. Fig. 1.—Front view of table, from the ground to top of table, 2 ft. 5 in.; S, legs of table, four in number, 2 ft. 4½ in. long, 2 in. wide, 1½ in. thick, secured to A (top of table) with screws; D are the leaves of the table—you can dispense with these, if you like—1 ft. long by 10 in. wide, ⅞ in. thick, secured to table by two hinges, 1½ in.; P are the stretchers for keeping leaves of table in position, 1 ft. long by 2 in. wide, ½ in. thick; A, top of table, 7⅛ in. wide, 2 ft. 4 in. long, ½ in. thick; if you do not have leaves to your table, you can then make the table what width you like, to suit your own purpose; E, treadle, secured by means of a small hinge, 1 ft. long, 4 in. wide, or, if you make the table wider, that will be wider, but not longer, in proportion; N are small pieces of wood, ¾ in. square, 2 in. long, to support cross-pieces marked T. Fig. 2 represents table reversed or bottom upwards, to show how stretchers are placed and secured. The two pieces of wood, P, are movable, as shown per dotted line, and are secured to the table by stout screws. Fig. 3 (there are three parts included in this).—We will take T first, it being a strip of wood 4 in. long by 2 in. wide, with a 1 in. square hole cut neatly through the centre; you require two of them, as in Fig. 1; they are to form a guide for the bottom cramp, marked C; Z is the most complicated part of the machine, it being a knuckle-joint. Without this you do not obtain a true vertical stroke. If you cannot make this, although very simple, I have another way, which I will explain in Fig. 5. To make this knuckle-joint, get a piece of iron ¾ in. wide, 1½ in. long, 1 in. thick. Cut the top flat, so as to suit the end of the arm. The lower part of the joint which holds the saw is part of any old frame filed to suit the lower slot, secured so as to work easy by means of a small rivet. Fig. 4 is the bottom cramp driven into a piece of 1 in. square wood 14 in. long (R); M is a small piece of wood driven through C to form a stop, so that, should the saw break, C cannot slip through T. Fig. 5.—If you cannot make the knuckle-joint, proceed as follows: Cut your old frame which you have been using, according to Fig. 5, at C; secured to arm with screws it makes a very good substitute, but not so good as the drawing F, Fig. 3. Fig. 6.—Stump of wood 6 in. long, 2 in. square, with a slot cut to allow arm of machine to work in; B is a ¾ in. ball to secure arms to stump A. Fig. 7.—Distance from S′ to S, 1 ft. 8 in.; from S′ to P, 8 in.—the whole to be ½ in. thick; O, piece of wood 1 in. by ½ in., to correspond with the length of the arm, secured, as you see in Fig. 7, with strips of indiarubber to form a spring; D is a guard to prevent the arm from rising too high when saw breaks: size, 1½ in. square; M, stay for legs, 1¾ in. by ½ in. Fig. 8 is front view of Fig. 5.—J. H. W.



Fret Machine and Parts.

**School Blackboards.**—J. J. (*Leeds*).—Refer to the Index of Work, Vol. II.

**Cutting Mounts.**—Omar.—It is a great pity to cut your old engravings, as by so doing you destroy any value there is in them. Some rare specimens of Hogarth's engravings fetch very high prices. The best method I should suggest is, procure sheets of card large enough to cover present margin, and have a suitable equal margin; measure size of engraved part, or that which you wish to appear, and mark the size in pencil square upon centre of your card with a sharp mount-cutter's knife; cut the centre out; procure a second cheap cardboard and lay your engraving flat thereon, just attaching the corners, and fix your mount over engraving to board you have the engraving on. You will then have it perfectly flat for framing, and can at any future time remove without injury should you wish to realise. There is also a special graining known in the trade as "Hogarth pattern," and designed by him for his engravings, and very suitable. I should consider in the way of mounts it is cheapest to get them cut by a mount cutter, for they will mount them without fear of injury in front and back mounts for 1s. 3d. complete, 2 ft. 6 in. by 1 ft. 10 in., with edge of bevel in gold or plainly cut, and you can have a variety of tints to select from. The City Frame Company, 29, Basinghall Street, E.C., are not far from your address, and are wholesale mount-cutters, and who would advise you as to whether your engravings would clean, as old engravings with their original margins are better than mounts, and can be cleaned if not too far gone.—G. R.

**French Clock.**—R. M. (*Liverpool*).—Before altering the snail make sure the fault is there, for if it has struck all right till now, the fault may be elsewhere. Take off hands and face and examine the wheels that carry the hands, and you will see a dot mark on each; arrange the three dots in a line with the pivots of the minute, and shake minute or cannon arbor, and then try if it strikes right, as this, if only one tooth is wrong, with a graduated snail is often sufficient to throw the whole striking wrong. If not right, see if either arm of the rack is loose, and rivet up if it is; then put on the minute hand and turn round, and see that rack hook falls fair and clear in each tooth as the wheels go round; if not, mark where they do not fall deep enough and slightly file the snail. Do not overdo it: better take a little twice than too much at once. I forgot to say, examine rack teeth and see if any are bent. Should the rack fall too far or not enough at *all the hours*, bend the rack arm that rests on the snail down or up a little, and test it at the one o'clock hour. To make a new snail, fit up a piece of brass on the hour wheel, put a sharp-pointed pin in the rack arm, put the rack hook in the first tooth, let the sharp pin rest on the new snail piece, hold the rack and hook steady, and turn the snail round. Now let another tooth of the rack down, and repeat the movement till twelve teeth of the rack have fallen and you have twelve circles on the snail piece. Next put your minute hand on and hold it up tight at twelve; let the rack fall on the twelve teeth; press the pin on the snail, at the same time drawing it fully up: this will give a radial line. Now turn the minute hand round an hour, and let rack down and draw it up; do this twelve times, then your snail will have twelve circles representing twelve hours, and twelve lines (radial), giving you the length the steps must be. Now all you have to do is to file down to the first circle the distance between two lines, between the next two, or, rather, one of the first you used and another; file down to the second circle, and so on till you have the twelve steps. You will find this the best way to mark it out, I think, as should your rack teeth be ever so uneven, having marked the snail by it, it is sure to drop right.—A. B. C.

**Algebraical Question.**—Mathematics.—You should submit your question to a scholastic paper. It would have no interest for the majority of our readers, and "Shop" space is valuable.

**Cocoa-Nut Fibre.**—J. I. (*Bath*).—Try the following places for the above:—Messrs. Treloar and Son, Ludgate Hill, London; Messrs. P. Maddin and Sons, 98, Borough High Street, S.E.; or write to Mr. A. Robottom, Commercial Sales Rooms, Mincing Lane, London, E.C.

**D Dulcimer.**—G. H. (*Camberwell*).—The measurements are taken "over all"—that is, including blocks and facings—and, as before stated, the distance from back to front is 1 ft. 4 in. It has forty brass and forty steel strings, divided into alternate groups of four each, commencing with brass

at the bottom. Making the soundboard thinner would hardly be likely to improve the tone. The only way to ensure a good tone is to use nothing but the best material, and to be very particular about the workmanship to see that everything is cleanly and neatly finished, and that no more varnish is used than is necessary to get a good face. For this reason a polished sounding-board is best. The piccolo D is half the size of the other in every way as far as the shell of the instrument is concerned. It has, however, the same number of notes, and consequently the same number of strings. Particulars of this are given, in reply to A PLAYER, in No. 90, page 615, Vol. II.—R. F.

**Sign-Writing Charges.**—CONSTANT READER.—I never attempt to give these: every man must find this out for himself, and all I can do is to refer you to Laxton's "Builders' Price Book," published annually by E. & S. Spon, Strand, London. There are, of course, all prices, a good workman naturally commanding a better figure than a poor hand, who is often willing to do work at a starvation price.—H. L. B.

**American Leather Cloth.**—C. L. L. (*Queen's Walk*).—The manufacture of this article was introduced from America about the year 1854, and met with a large sale up to 1861, when it fell off greatly. We are not aware that the composition was ever made public, nor do we know much about it. A Mr. Dodge, however, is said to have taken some patents for its manufacture, and we believe he originally introduced it here. We do not think it could be used as proposed by our correspondent, but requires to have special plant and means provided for its manufacture and use. There is, or was some years since, a large factory for its manufacture at East or West Ham, or somewhere in that neighbourhood; but whether it is still in operation we do not know. If our correspondent would state clearly exactly what he wants to do, perhaps we might be able to help him.—C. E.

**Royal Navy Carpenter.**—DARKEY.—In many cases, if not in all, carpenters in the Royal Navy are obtained by the Government from the dockyards. Applicant will, of course, have to be physically fit to be a seaman. You do not state age or give any idea of educational or mechanical attainment. Apply by letter to the nearest dockyard. The pay is £50; officer, £100 to £150; chief carpenter, £164; extras, £5. The above (if you can get it) is better than artificer in Royal Engineers—the pay is 1s. 11d. per day extra to regimental pay.—B. A. B.

**Hair Sieve Bottoms.**—C. B. (*London, E.C.*).—You should make your address known to HOOPBENDER by advertising it in our cheap "Sale and Exchange" column.

**Engraving on Metals.**—PERGY.—This subject has been treated in WORK, with full illustrations, and will be found in Nos. 35, 38, 43, 45, and 48. Messrs. Field & Tuer, Leadenhall Press, London, E.C., publish a shilling book of letterings. Fairbairn's "Crests and Monograms," price 42s. (Lewin, 20, Ludgate Hill, London, E.C.), will probably suit you; and Messrs. J. Sellers & Son will supply you with a complete outfit of engravers' tools. Consult "Shop" in back numbers for "wrinkles."—N. M.

**Engravers' Wages.**—F. M. T. (*Swansea*).—You ask for information as to the wages of engravers. It is a large subject, and requires treatment from various standpoints. Broadly speaking, the wages of an engraver range from 12s. up to 120s. per week. You will quite understand that there are engravers and engravers. A general engraver is not often found as a journeyman; the simple fact of his being able to take up and execute general work enables him to take a small workshop and work for his own individual profit; and his earnings may be from 30s. to 50s. per week. Working under such a master, the engraver would receive from 4d. to 8d. per hour, according to ability, as, of course, the master wants a profit on his employee's work, as well as to pay his portion of shop-room, firing, and lighting. Heraldic and inscription engravers will earn about from 9d. to 1s. per hour, depending on ability and continuous work. I know nothing of the present prices of door-plate work, but should know what to charge if I had one to cut, much depending on the size and style of letterings.—N. M.

**Cutting Stencil Plates.**—W. E. T. (*Hibbard*).—The plates may be cut in a fly-press, but the expense of the cutting-out tools will be very great, unless a great quantity were required. They can be filed out beautifully clear, requiring nothing but a little flattening. The best way of cutting out only a few stencil plates is with the graver, as follows: First, procure a piece of hardish wood, and have it planed smooth; next procure some sheet zinc of the proper thinness, and cut out to the required size. These will not be quite flat, therefore get two sheets of steel of any convenient size *larger* than your sheets of zinc, and about ¼ in. thick. Place these sheets of steel in the fire until hot—not red-hot—and place half a dozen or so of zinc plates between them, and then and there screw them up tightly in the vice until cold, when they will be found to be flat. Next cut out of cardboard the letters you are desirous of cutting in stencil, and mark them in outline on the zinc with a sharp point or etching needle; bore a small hole at each corner, and tack down with a common iron tack. Next sharpen a "lozenge" graver (see Indices Vols. I. and II.) rather, but not too acute an angle, and cut away till you cut through the zinc. If you are not used to handle a graver, you will require considerable practice; but with courage and perseverance all may succeed, and stencil cutting is not so difficult as some other kinds of work.—N. M.

**Cutting Machine.**—A. R. B. (*Dublin*).—There is no reason why such a machine should not work well, provided (1) That the board is well supported *up to the extreme end;* (2) that the cutter has some traversing as well as descending movement; (3) that the cutter is sharp and thin; (4) that only small pieces are removed at a stroke; (5) that the workman has ample power. Given wood cut to the proper lengths and at the proper angle, very little shooting is needed, and end grain is not very often used as a glue joint.—B. A. B.

**Corrosive Sublimate (or Chloride of Mercury).**—BUSYBODY.—This may be obtained at any chemist's, and costs about 4d. per oz. Block or pure tin can be had at almost any ironmonger's, and certainly of any dealer in plumbers' requisites. See reply to AMATEUR (page 13, No. 105, Vol. III.).—OPIFEX.

**Combined Clothes and Tool Chest.**—A. R. (*Somerton*).—Considerable annoyance would probably result by storing your clothes and tools together in one box; but by adopting my present suggestions you would not experience trouble in gaining access to either a tool or a garment. Two boxes are what I advise you to use—hinged together

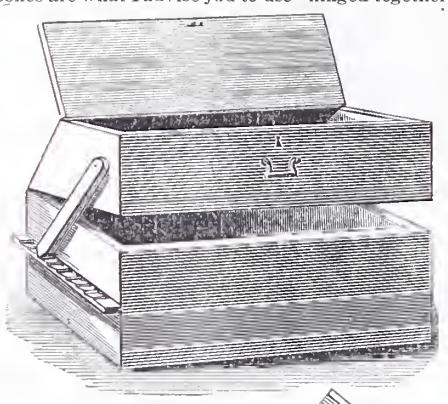


Fig. 1.

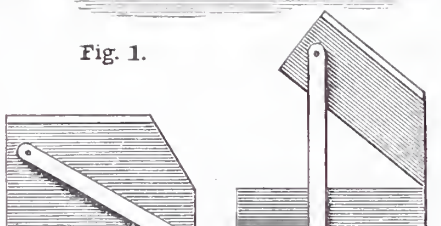

Fig 2. Fig. 3.

Combined Clothes and Tool Chest. Fig. 1.—Chest shown open. Figs. 2 and 3.—End Elevation, showing Box closed and open respectively.

on one side as in Fig 1. The back of the top one should be at other than a right angle to its bottom, to permit of its being opened sufficiently when required. At each, or only one, side of the upper chest, outside, pivot one end of a rail, allowing the other end to rest upon a notched gallery on the side of the lower chest. When the top one is lifted, the rail or rails, as the case may be, would retain it in that particular position.—J. S.

**Clarionet Pitch.**—TOPPER.—Your clarionet is a half-tone *too flat* for your piano. Clarionet players, as a rule, have a difficulty in getting down to the pitch of pianos, which are nearly always more or less flat. We think TOPPER must have a clarionet made in the French pitch or "diapason normal," which would be about a semitone below English pitch. If this be the case, it is impossible to bring the instrument up. Clarionets can be sharpened slightly to the extent of less than a quarter of a tone without affecting their *justesse* by removing the German silver tip from the barrel or socket of the instrument—*i.e.*, the small section which receives the mouthpiece and top of the first joint—and turning it down about the width of the tip—say ⅛ in. If it be a large bore clarionet, it would bear a little more; but it is not safe to go much beyond this, as if shortened too much it will throw the instrument out of tune, making the notes in the bottom register too flat and in the upper register too sharp. Instead of running the risk of spoiling his present socket, TOPPER would do well to buy from some musical instrument maker a "sharp" socket—that is, if his instrument is in the *English* pitch; for, as already stated, if it is in French pitch it cannot be brought up.—G.

**Darkening Bronze.**—J. E. (*Loughborough Junction*).—There are so many kinds of bronzes, each varying in colour and treatment so much, that, unless you give further particulars, it is difficult to advise you. Perhaps your panel is lacquered; and, if so, that would account for your not being able to darken it by exposure to the air.—R. A.

**Soldering Lamp.**—H. P. (*Shepherd's Bush*).—Consult the Indices to the two volumes of WORK already published, and search them through before asking queries, as the back numbers can always be had of Cassell & Co., London, E.C.—R. A.

**Black for Lamp Stand.**—BARRON.—Yes; you are quite right in supposing that Brunswick black is unsuitable for this purpose. You will find Berlin black very good for the job, because it dries with a nice, smooth, dead black; and if you brush it over when thoroughly dry with a rather soft brush, it takes a nice dull polish, if such a term can be applied to a dead black. Be sure to ask for Berlin black. It is sold at most ironmongers', 6d. and 1s. per bottle.—R. A.

**Moderator Lamp.**—A. L. (*London, S.E.*).—These lamps can be procured new at Gardner's, Charing Cross, or at Burton's (late Rippon & Burton), Oxford Street, and, in fact, at most high-class ironmongers'. But you would probably get one very cheaply by advertising for it in the "Exchange" column of WORK. Prices of new ones range from 12s. 6d. to 12 guineas. The quantity of oil per hour that a lamp of this kind would consume depends on the height it burns at and the size of the wick, but about 7½ hours to the pint is a fair average.—R. A.

**Building and Accommodation.**—A. C. (*Loveclough*).—I must take it for granted you wish the people to sit down. If this is so, you can easily get at the sitting accommodation of a floor space 40 ft. by 30 feet by taking the seat of an ordinary chair as being 1 ft. 6 in. by 1 ft. 6 in. Now allow 1 ft. 6 in. in front of the chair for the knees of the person sitting down, and this will just (and only just) allow of people passing in front without compelling the sitter to rise every time anyone passes in front of him or her, as the case may be. This gives us the exact space one person will occupy when sitting down—viz., 1 ft. 6 in. by 3 ft. 0 in., or 4 ft. 6 in. sup., occupied by one person. There are 1,200 ft. sup. in your room, so that as many 4 ft. 6 in. there are in 1,200 ft. will be the number of people the room will hold. You must make your own deductions for gangways, tables, or platform, seeing that you give me no particulars. You would find by setting the size of the room out to scale on a sheet of paper, and the size of one chair and the allotted space in front of chair out to the same scale on a piece of thin card, by cutting out the card and placing it on the paper, that you could move it about and at once see what you wanted.—E. D.

**Fountains.**—F. M. (*Manchester*).—I am not quite clear as to what you mean by "small illuminated fountains," or whether they are wanted for in- or out-door use. Write again.—C. M. W.

**Paraffin Lamps.**—ALADDIN.—Fig. 17, page 696, Vol. II., No. 95, is just the lamp you want, even to the silk fringe. The opal saucers used on the Argand gas lamps to soften the light will slide over the chimney of this lamp down to the level of the top of the wick. Some are large enough to go right down to the burner. If you want a fancy paper shade, you will have to make a wire support, of the kind used to support the common green card shades. That you could make yourself if you can solder. If you want it suspended at one fixed height, you have only to hook the three chains together at the top. I cannot tell you where you can get a lamp similar in design to the one you wish for, as, if I have correctly understood your requirement that the chains shall be easily detachable, you want the lamp to stand on the table on occasion; and I have never seen a lamp for sale similar to Fig. 17 on page 696, the chief recommendation of which is the possibility of using it as a hanging or standing lamp. If you are content to forego this advantage, and wish to buy one ready made, you can see a very good variety at Messrs. Benetfink's, 107 and 108, Cheapside, London, or you can write for their list.—THOMASO.

**Obtaining a Patent.**—DELTA.—The Patent Office rules state that—"On the acceptance of the complete specification, the comptroller shall advertise the acceptance; and the application and specification, or specifications, with the drawings (if any), shall be open to public inspection. Any person may, at any time within two months from the date of the advertisement of the acceptance of a complete specification, give notice at the Patent Office of opposition to the grant of the patent, on the ground of the applicant having obtained the invention from him, or from a person of whom he is the legal representative, or on the ground that the invention has been patented in this country on an application of prior date, or on the ground of an examiner having reported to the comptroller that the specification appears to him to comprise the same invention as is comprised in a specification bearing the same or a similar title, and accompanying a previous application; but on *no other ground.* If there is no opposition, or, in case of opposition, if the determination is in favour of the grant of a patent, the comptroller shall cause a patent to be sealed with the seal of the Patent Office." There are two modes of applying for the grant of a patent—one in which a provisional specification is lodged with the application, which, when accepted, is kept quite secret and never printed unless and until the patent is completed, and the complete specification filed. On the acceptance of this provisional specification, the applicant is at once protected, and has to complete his invention and

file his complete specification within nine months from the date of his application, on the acceptance of which, and after the expiry of the time granted for opposition, the patent will be sealed and issued. The other plan is by filing the complete specification and drawings *with* the application for the grant of a patent; but in this case the nine months' protection is lost, and nothing further in the way of improvement or addition which may be found desirable can be made to the patent, but another patent, embodying the additional improvements or knowledge, would have to be applied for, with the disadvantage that the acceptance of the documents by the office at once renders them accessible to the public, as has before been shown by the quotation from the rules. Both plans have their advantages; but great experience is required to know when and how to adopt each or either. The rules state that "A patent shall be sealed as soon as may be, and not after the expiration of fiftcen months from the date of application, except in the cases hereinafter mentioned," whieh do not enter into the nature of our correspondent's inquiries.—C. E.

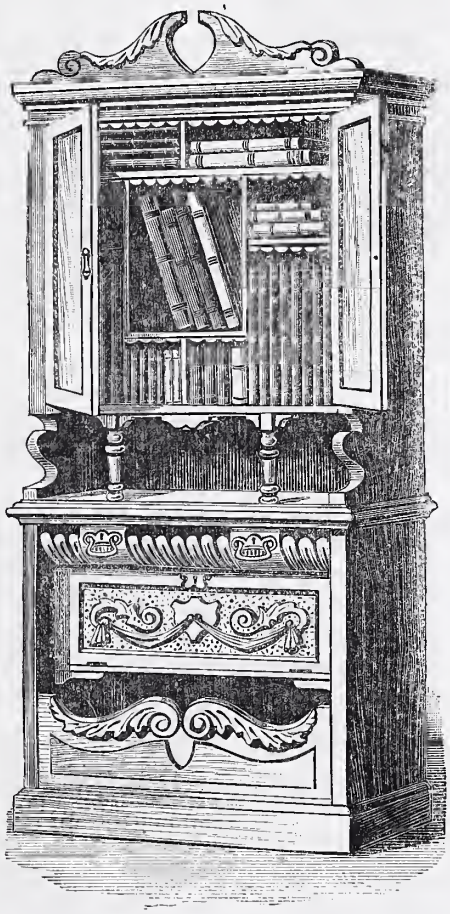
**Schools of Electrical Engineering.**—W. R. (*Carlisle*).—I have the opinion of a gentleman who is acquainted with the three schools mentioned. He places them in the following order of merit:—(1) City and Guilds of London Technical College, Leonard Strcet, Finsbury, London, E.C., with Professor Silvanus P. Thompson at the head of the Electrical Engineering Department; (2) School of Electrical Engineering, 12, Princes Street, Hanover Square, London, W., with Chas. Capito as senior instructor; (3) the Electrical Standardising, Testing, and Training Institution, Faraday House, Charing Cross Road, London, W.C., a new institution of great promise. Terms and a list of fees can be obtained by writing to the secretaries of these institutions. You will, perhaps, prefer a college nearer home. In that case, try University College, Liverpool, or Owens College, Manchester. As this profession is now in its youth, there are good prospects for a young man with an abundance of good health and plenty of "real grit" in his constitution.—G. E. B.

**Advice to Young Workman.**—DENNY.—My advice to you, and all like you, who have nearly learnt a trade, is to stick to the trade you have learnt until you can clearly see your way into another. You wisb to be an electrical engineer. I sketched out for you the course I could recommend in my reply to you on p. 702, Vol. II. of WORK. I do not know of a firm that would take you as "improver," and pay you sufficient wages to maintain you. Electrical engineers want premiums with pupils. The galvanometer you propose would be almost useless to an electrical engineer, but might suit a telegraph or telephone linesman. Make the instrument as Mr. Allsop directs, but do not follow your own notions of improvement until you have made an instrument strictly on the lines of the directions given you by Mr. Allsop. He is a practical electrical engineer, one who has *worked* his way up in the profession. An electrical engineer must not only know all the theoretical rules of electrical engineering, but must also have put them into practice by years of hard work. Should you see a chance of getting into an engineering firm where they make electric apparatus, such as dynamos, etc., seize the opportunity, and put in your best work.—G. E. B.

**Squeezing Wax for Carvers.** — J. W. B. (*Huddersfield*).—There seems no reason why the squeezing wax made acecording to the recipe to which you refer should not remain in a usable condition "for years," but I have not tried its durability, so cannot say. From the ingredients, I should say that it can be softened at any time by heat. A wax that constantly remains soft and has no tendency to harden would be as defective as one whieh could only be used once because it gets hard. I should think you might build up plaster of Paris on wood, and then carve it; but I do not know that this method is much practised, if at all. Surely it would be better to cast in the plaster if you want more than one copy of the same pattern; or if only one is wanted, carve it in some suitable material.—D. A.

**Etching Letters on Glass.**—EMBOSSTYRO.—(1) In answer to your first question—"What acid is used in glass embossing?"—if you wish for clear letters, you must use hydrofluoric acid; but if you want a ground appearance the gas must be employed—made by mixing fluoride of calcium and sulphuric acid together, and afterwards heating; directions for which you will find in WORK, No. 82, p. 487, or I will repeat for your benefit if you have not got it. And by all means stop out with Brunswick black, if you like that best. (2) No colours are used. You cannot get coloured letters by this method; but white letters upon a coloured glass are very easily obtained by using flushed glass of any desired tint, and after stopping out, pouring the acid upon the flashed side; it soon eats through this, and leaves exposed the white glass underneath. I hardly think you know what glass embossing is, and, of course, I cannot tell how the glass you refer to is done, as I have never seen it. In embossing, or etching, as it is properly called, all the parts unprotected—*i.e.*, not stopped out—are eaten away by the acid, and if it was left on long enough it would go quite through the glass (therefore it can never be kept in glass bottles, but in something it will not touch: gutta-percha, for instance); and although, as you say in your letter, by it you can "put a name or inscription of any kind on a shop or other window or glass door," yet, as I have before explained, the letters or designs will be white. But if it is simply gilt letters you wish to put on glass, why go to the trouble of etehing first? However, by this and other pieces upon the same subject, which you will, no doubt, have seen before this can appear, you will, I hope, have learnt what etching is, and if it is what you want, I have no doubt you will succeed, as it is not at all difficult; but if you know nothing of this acid, let me caution you to be very careful in using. It produces bad sores if dropped upon the flesh, and the gas is very injurious to breathe.—W. E. D., JR.

**Bookcase.**—WELL-WISHER.—I have designed the bookcase here shown, hoping that it may contain a suggestion or two of service to you. If the shaping and fitting of the shelves are not beyond your skill, I should advise you to scatter them in some such manner as that shown. The spaces would then be very convenient for the reception of your large volumes. You can either construct the top carcase to terminate in the brackets, or at the bottom of the latter join a moulded board, and



Bookcase.

screw the top carcase to the lower one. In the under carcase I have intended that the cupboard shall lay back a few inches, and have a flap door. In making the drawer, have a flat front joined perpendiecularly to the sides, and glue and screw a curved-front plain or carved piece along it. I have introduced a shaped piece attached on the front of the job at the bottom, to hide any loose articles whieh might occasionally be thrown into the recess, whose appearance, perhaps, would not tend to enhance the good looks of a piece of furniturc.—J. S.

**Polishing.**—X. L. U. M. (*Hebden Bridge*).—Either wax or oil polishing would suit your old cabinet. It could afterwards be French polished, but I should strongly recommend you not to have this done. French polish on such a piece of work would be quite out of place.—D. D.

**Bending Fretwork.**—E. C. (*Bristol*).—Does it not stand to reason that a piece of wood 12 in. long by 1¾ in. to 2¼ in. wide cannot be "rounded to a 2 in. diameter circle," either by bending or otherwise? I am inclined to think you have misinterpreted the instructions or drawings to whieh you are working. I can only suggest that the mysterious circles should be either turned or sawn according to their size. I suppose these pieces form the "concave and convex sides" to which you refer.—D. D.

**Wood-Carving Designs.**—A. L. W. (*Aberystwith*).—You can obtain a list of printed designs and photographs by writing to the Manager, School of Wood Carving, Exhibition Road, South Kensington. Write also for a list of photographs of carvings to Bedford Lemere & Co., 147, Strand, London, W.C. Write also to Mr. G. A. Rogers, Maddox Street, London, W.—M. E. R.

**Pedestal Dressing-Table.**—YOUNG HAND.—The drawer runners of a pedestal dressing-table should be tongued (*i.e.*, the boards should be rebated on the top and bottom surfaces at the side ends, leaving projections from back to front), and fit into grooves on the inner surfaces of the sideboards. Plinths should be separately made, and screwed, from underneath, to boards which should be joined to the bottom of the sideboards. Either a whole board, framing, or beams, may be used within the four dovetailed boards of each plinth; the top surface of the former, in whichever case may be preferred, being a distance down from the top edges of the plinth boards equal to nearly a thickness of a drawer-runner. If you had referred to the articles I named in the reply to which you allude (page 325, No. 72, Vol. II.), you would have gained some insight concerning plinths. Look also to "A Writing Cupboard."—J. S.

**Mounting Lenses.**—LENSES.—There is no hard and fast rule for mounting, as this is determined by the lenses themselves. The best distance of the stops from the lens must be determined by actual experiment. Portrait and rectilinear lenses must almost invariably have the stops plaeed half-way between the two combinations as the most effective position; with landscape lenses a short distance in front. The nearer the stop is to the front of a landscape or single lens, the greater is the field covered, and also the greater the curvature of the lines. The farther away (of course in reason) the straighter the lines, but the smaller the field. In placing the stops, a compromise must be made to obtain as straight lines and cover as large an arca as the lens is capable of. As to the sizes of the stops, no universal plan is adopted. The size of the openings is arbitrary. The Photographic Society of Great Britain introduced a uniform system based on 4 as the largest opening, each stop in succession smaller, requiring an exposure of double the time of the next largest. Very many lenses have their stops made in accordance with their focal length. The expressions F8, F16, F32 mean respectively that F8 is the diameter of the stop and one-eighth part of the focal length of the lens, measured from the back lens to the ground glass of the focussing screen; F16 means a sixteenth part of the focal length, and as the light diminishes according to the square of the distance, F16 would require four times as long exposure as F8, and so on with the other sizes.—D.

**Bone Handles for Table-Knives.**—F. G. H. (*Islington*).—The table cutlery trade is almost entirely confined to Sheffield, and unless F. G. H. can get what he wants through some friendly working cutler (*i.e.*, mender), we doubt whether he can do so except at that place. A Sheffield directory will give him the address of a dealer in such things. African ivory is used for all the best knives; the bone for the inferior ones is mainly imported from South Ameriea.—S. W.

**Battery.**—W. H. Y. (*Battersea*).—An article on the Austin Leclanché battery appeared in No. 84.

**Incubator.**—WHITE LEGHORN.—I gather that you have made a hot-air machine on Hillier's principle which answers well, but as you have not tried it you do not know whether it will succeed or not. If you will send me a rough sketeh, with full particulars, I will give you my opinion of it. In my promised article you will have described a thoroughly reliable machine, which you can get ready in good time for next season's hatching.—LEGHORN.

**Greenhouses.**—C. S. (*London, N.W.*).—If you will examine the published Indexes to WORK, Vols. I. and II., you will find much already existing on greenhouses. WORK is issued both monthly and weekly. You are entitled to the presentation plate issued, gratis, with No. 105 of WORK.

**Lithographic Stone Press.**—G. A. (*Edinburgh*).—You should advertise your Quarter-sheet Litho. Press in WORK.

**Fretwork Machine.**—F. F. (*Leeds*).—If you wish to make a Fret machine, consult Indexes to Vols. I. and II. of WORK. There is a mass of matter in WORK relating to fret machines.

**Price for Shed.**—HEATHFIELDS.—You omit to say what the scantling of the oak posts are, also who is to make the shed and erect it; for if the carpenter frames and fits the various pieces together at his place, it must be taken to pieces before you can bring it away. You likewise make no mention of tie beams, or if the wood is to be wrought or not. I give below a fair price for the different sizes of stuff you mention, taking my own idea of the size of oak posts required. These prices are for stuff in the rough, not planed. This, I think, will be sufficient guide for your purpose.

| | | | |
|---|---|---|---|
| 6 in. by 6 in. oak posts, per foot run, | | 1s. to 1s. 3d. | About. |
| 4 in. by 4½ in. yellow deal | ,, | 2½d. | |
| 3 in. by 4½ in. | ,, | 2d. | |
| 2 in. by 4 in. | ,, | 2d. | |

—E. D.

**Contents of Saucepans.**—HOLLOW-WARE.—To find the contents of the part outside the dotted lines, multiply the area of the space contained between the dotted line and the outside of the vessel by the circumference of a circle passing through the centre of gravity of that space. The area of the space referred to will be very nearly equal to the length of the dotted line (or height of

the vessel) multiplied by two-thirds of the breadth of space at centre. To find the centre of gravity of the area, draw it on fine card or stiff paper, cut it out, and hang it up freely on a pin by one end. On the same pin hang a plumb-line, and mark its position on the paper. Then in like manner hang the paper up on the pin by its other end, and where the plumb-line crosses the line drawn previously on the paper will be the centre of gravity. The distance of this point from the centre of the saucepan will be the radius of the required circle. If the vessel is in existence, you can get its contents by finding the weight of water it holds, taking the difference of its weight when full and when empty in pounds, and dividing by 62·37 to give the contents in cubic feet, or by 10 to give the contents in gallons. —F. C.

**Electrotype Copies of Printer's Type.**—COMPO.—The tools required will be: A moulding case—*i.e.*, a shallow brass pan to hold the cake of wax forming the mould—a clean copper or iron ladle to melt the wax in, a steam-jacketed pan for melting the wax and heating the moulding case, a set of "building irons," a shave knife, a press capable of taking forme, mould, and mould case, and a set of soft-haired brushes for the blackleading process. In addition to these, you will require a vat for the electrotyping solution, a battery of large cells, or a dynamo-electric machine to furnish current for the process, a backing tray, soldering tools, planing machine, and many other appliances found necessary in an electrotyper's workshop to finish the electro, and mount it ready for the printers. The materials required will be: Some best yellow beeswax for the moulds, sulphate of copper for the electrotyping solution, pure sheet copper for the anodes, best plumbago or blacklead for the mould, solder to "tint" the electro, stereotype metal to back it with, and wood blocks to mount the electros type high when finished. The type to be copied in this way must be specially set up for the purpose. The type should have a good bevel, as should also the rules and leads. All rules and leads should be thick. The quads, reglets, and spaces must be high, pages and blank spaces must be guarded, and the formes locked up tighter than for ordinary printing. The necessary quantity of beeswax should be melted by steam, and poured into the previously warmed moulding case from a clean ladle. The filled case must be kept level until the cake of wax is cool. The forme must be cleaned thoroughly, dried, and carefully blackleaded. Then the face of the type must be placed true with the face of the cake of wax in the moulding case, and the two pressed together in the press, so as to drive the wax of the mould into every crevice of the type. When this is done, and the forme removed, the mould must be well coated with dry, finely powdered plumbago, brushed well into every crevice with soft, long-haired brushes. The blackleaded surface is then connected to copper strips embedded in the mould, and placed in the electrotyping bath until it receives the necessary thickness of copper shell. This is removed from the mould, and placed face downwards in a backing tray floated on a bath of hot stereo metal, where it is first tinned with solder, then backed with a layer of stereo metal. The edges are then trimmed, and the electro mounted in the usual way on type-high blocks of wood. This is a brief outline of the method. For full and illustrated details of the process, get Mr. Watt's book on "Electro-Deposition," in which eighteen pages are devoted to the subject, and much other useful information given.—G. E. B.

**Camera Bellows.**—M. A. (*Maidenhead*).—The bellows can be purchased at most camera makers. Some firms make a speciality of supplying camera fittings of all kinds. No special tools are required in the process, which is exceedingly simple. H. Park, 5, Station Buildings, Acton Street, Kingsland Road, London, N., might supply your requirements.—D.

## III.—QUESTIONS SUBMITTED TO CORRESPONDENTS.

**Printers' Oil.**—F. J. R. (*Bursledm*) will be obliged for a good recipe for making printers' ink as used for ceramic work of copper plates.

**Steel Lacquer.**—J. B. (*Tyldesley*) writes:—"Will any reader tell me of a good steel lacquer, or give me the address of anyone who makes or sells it?"

**Glossy Ticket Ink.**—A. H. (*Oldham*) writes:—"Can any correspondent say where I can get glossy black ink for ticket writing ready for use?"

**Artists' Easel.**—S. A. W. (*Wallasey*) writes:—"Will any reader oblige me with full instructions of the working of, and how to make, a neat portable artists' easel?"

**Cotton Belting.**—S. A. & Co. (*Stockport*) write:—"Will any correspondent point out a good remedy to prevent injury to cotton belting where the friction is very great?"

**Colouring Gun.**—GUN writes:—"I have a gun, the barrel of which has been black, but has worn off. Can anyone tell me how I can black same? Also if I can 'blue' the bright parts without getting them hot, and how?"

**Canoe.**—J. G. (*Sunderland*) writes:—"Would any able reader give me the design of a canoe of simple make, with a few hints as to its construction?"

**Turned Balusters.**—F. E. H. (*Lancaster*) writes:—"I shall be glad to be informed of any turner who can supply me with these."

**Rope Pulleys.**—T. P. S. (*Tudhoe Grange*) writes:—"Will any reader give me a rule to work the proportions of rope pulleys that are used for winding engines at collieries? I want one to work with a working load of seven tons, including ropes, eages, and tubs. I cannot find one to suit."

**Pyrotechny.**—F. W. T. (*Heathfield*) writes:—"Will any reader kindly inform me where I can obtain the following works on Pyroteehny—a work by Practieus, a French work by Chertier, a volume by Brown, and one by Thomas Kentish?"

**Index Rerum.**—J. B. (*No Address*) would be glad to be informed how to set about making this article.

## IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**Leclanché Battery.**—M. (*Bishop Auckland*) writes, in reply to C. F. W. N. (*Forest Gate*) (see page 78, Vol. III.):—"You can procure Leclanché batteries from Mr. Bowron, electrician, 93, Praed Street, London, from 1s. and upwards."

**Books on Coach Building.**—COACH BUILDER writes, in answer to YOUNG WHEELER (see page 829, Vol. II.):—"There are the following works on coach building: Budd, "Carriage Suspension" (2s. 6d.); Philipson, "Coach Body Making" (4s. 6d.); Boag, "Coach Painting" (12s. 6d.); Mattison, "Coach Body Making explained Geometrically and Mechanically"—to be had of Thos. Mattison, carriage draughtsman, Southampton—(price 10s. 6d.); Foggett, "Carriage Springs" (2s. 6d.); Philipson, "Carriage Suspension" (4s. 6d.); Foggett, "Carriage Wheels" (2s. 6d.), "Carriage Timber" (2s. 6d.); Philipson, "Draught" (2s. 6d.), which can be had of John Kemp & Co., 46, Cannon Street, London."

**Leclanché Battery.**—THE ELECTRICAL COMPANY (*Crewkerne*) write, in reply to C. F. W. N. (*Forest Gate*) (see page 78, Vol. III.):—"Our prices for Leclanché batteries are: No. 1, 1s. 6d.; No. 2, 2s.; No. 3, 3s."

**Lace Frame.**—W. B. (*Camberwell*) writes, in answer to MART (see page 14, Vol. III.): "He must get a board 20 in. by 6 in., and ½ in. thick, across the ends of which then fasten a piece of wood 2 in. by 1 in. substance, 6 in. long, the 1 in. side to be fastened to the board. Along the tops of each end piece bore a row of holes—about twelve—to take small screws, to which the work is fastened."

**Incubator Regulator.**—H. H. S. writes, in reply to W. P. B. (*Colnbrook*) (see page 78, Vol. III.):—"The difficulty of making a regulator is not great, but when such regulators as Hearson's patent capsule can be obtained for 10s. 2d. or so, it seems hardly worth risking a break-down by making one. W. P. B. may make one of a U tube having one end closed, and putting a little ether at the closed end, and filling up with mercury, on which rests a float which is connected with the damper."

**Turned Wood Cases.**—F. C. (*Liverpool*) writes, in reply to W. H. (*Stirling*) (see page 14, Vol. III.): "P. Macmuldrow & Co., 168, London Road, Liverpool, make turned cases such as you require."

**Joiners' Bits.**—C. A. N. (*Wolverhampton*) writes, in answer to A. A. W. (*Leicester*) (see page 734, Vol. II.):—"I beg to say that he can inspect or purchase any of the bits used by joiners at any good tool shop, and also have them thoroughly explained. But I would like to call attention to an expanding centre-bit which was brought under my notice through your paper, and which is certainly the most clever and ingenious little tool I have bought for some time. They are made in three sizes, viz., ⅝ in., ⅞ in., and 1 in., and cut any hole up to double their size; so that with the three bits you can cut any sized hole, from ⅛ in. up to 2 in., to a hair's-breadth. They are sold at 1s. 6d., 2s., and 3s. One very important thing about them is a small regulating screw at the side, which prevents the sliding cutter from expanding during the act of boring. I wrote direct to the inventor for mine after reading the article in your paper, WORK—a Mr. Anderson, 3, Poulton Road, Seacombe, Cheshire—and I consider them a valuable addition to my stock of joiners' bits."

## V.—BRIEF ACKNOWLEDGMENTS.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—AMATEUR PRINTER; B. Co. (*Colchester*); G. W. Y. (*Wolverhampton*); W. L. (*No Address*); F. H. (*Rochdale*); E. L. (*Bath*); G. T. (*Hollingwood*); J. F. (*Elgin*); J. F. (*Sandbach*); C. T. E. (*Somerset*); R. J. (*Leominster*); L. U. M. (*Hebden Bridge*); AN AMATEUR; J. C. (*Chelsea*); A. C. (*Leicester*); J. H. (*Wolverhampton*); G. P. (*Bebington*); A. H. (*Manchester*); BERTIE; G. H. (*Newcastle*); W. H. (*Penzance*); G. H. S. (*West Kensington*); G. W. W. (*Thornton Heath*); T. S. (*Morpeth*); W. J. B. (*Deptford*); E. H. (*Sunderland*); R. W. V. (*Camberwell*); M. H. M. (*Hull*); H. H. L. (*Bebington*); J. R. # PHOTOGRAPHY FOR AMATEURS.

A Non-Technical Manual for the Use of All. By *T. C. HEPWORTH.* With Illustrations.

"One of the most thorough and efficient manuals for the non-professional photographer has been written by Mr. T. C. Hepworth. It deals with everything which an amateur should know, not from a hazy, semi-scientific point of view, but from a really practicable standpoint. All the many difficulties which amateurs are likely to encounter, and the many errors into which they are almost certain to fall, are foreseen and provided against, while numerous ingenious hints are given so as to make the amateur's labours as easy as possible. Mr. Hepworth has an intimate knowledge of photographic science, and his book will be welcomed by all amateurs."—*Graphic.*

VOL. III.—No. 115.] SATURDAY, MAY 30, 1891. [PRICE ONE PENNY.

### A PORCH FOR A COTTAGE OR SMALL VILLA.

BY ARTHUR YORKE.

MATERIALS — DIMENSIONS — CONSTRUCTION OF FRAMEWORK—FILLING IN THE FRONT—THE ENDS—THE ROOF AND ITS ARRANGEMENTS.

*Materials and Dimensions.* — The porch for which a design is now given is provided with seats, and is intended for houses standing in their own gardens, and to some extent secluded from observation. It is built with straight stuff, the heavier parts being supposed to be of some one of the straight-growing fir woods, and by preference of larch, which is best and most enduring. Its dimensions are such as are suited to a small house. It projects 3 ft. from the wall, is 6 ft. wide, and 6 ft. high to the lintel. The perspective view (Fig. 1) and Figs. 4 and 6 are not drawn to scale; Figs. 2, 3, and 5 are drawn $\frac{1}{2}$ in. to the foot.

*The Framework.* — In the ground plan (Fig. 2), it will be seen that the front is supported on four collar-posts, *a*, *a*, *a*, *a*. These are cut from so many rough larch poles—say $3\frac{1}{2}$ in. or 4 in. at base, and not much less at top, for plantation-grown larch tapers very gradually. They rise 6 ft. above the ground-line. The best way of setting them is on blocks of stone, where the post will be prevented from moving by an iron dowel let into the stone and the bottom of the post. Since, however, this rustic work is perhaps most frequently followed by the non-professional workman, who will prefer an easier method, it should be said that it will suffice to let them into the ground, like ordinary gate-posts, for a couple of feet, and to well ram them in with stones and earth. If this last plan is adopted, it will be well roughly to shave off the bark from the part to be buried, and to gas-tar it. Though more liable to rot than when mounted on a stone, a well-seasoned larch-post, thus treated, will last for many years.

The back-posts, *b*, *b*, are of poles sawn in half, and nailed to plugs driven into the masonry. The nails alone will hold them in place, as also the dwarf-posts *c*, *c*, which are 14 in. high, and support the corners of the seats.

On the top of the four front collar-posts rests the lintel, which is nailed down to them, and over the two corner-posts it is cut half through to receive the wall plates (*d*, Fig. 3), which here rest upon it. These wall plates, it will be seen from the figure just named, are 3 ft. 3 in. long, and so project 3 in. beyond the collar-posts. This allows the front rafters to be set slightly farther forward than the posts, which will thus be better sheltered by the roof. At top the rafters

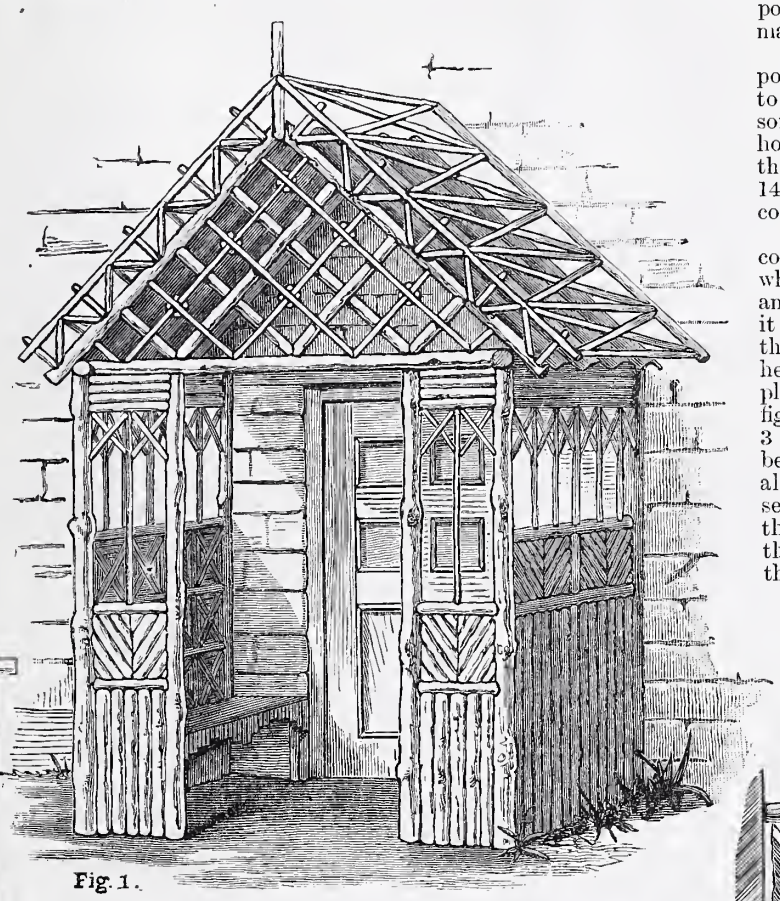

Fig. 1.

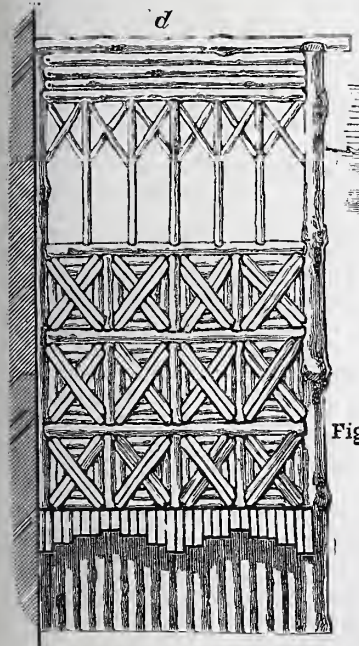

Fig. 3.

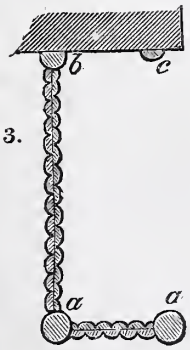

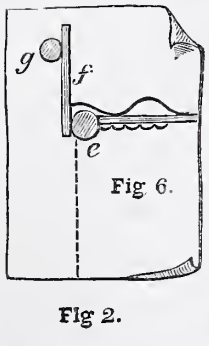

Fig. 6.

Fig 2.

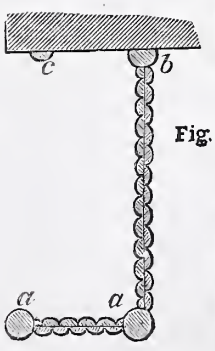

Fig. 5.

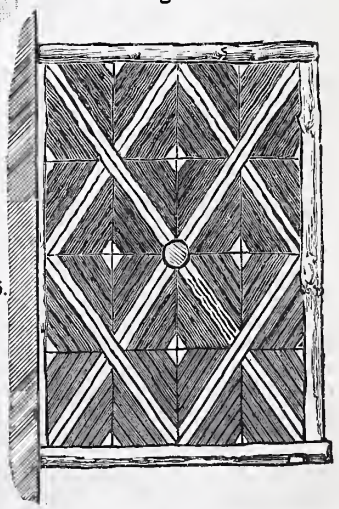

Fig. 1.—Perspective View of Rustic Porch for Cottage or Small Villa. Fig. 2.—Ground Plan. Fig. 3.—View of Side as finished within. Fig. 4.—Rafter Ends showing Mode of Connection with Ridge-Pole. Fig. 5.—Ceiling. Fig. 6.—Support of Trellis for Climbers.

are cut to clip the rustic ridge-piece, as in Fig. 4. The back rafters are, of course, of half stuff, and are nailed to the wall.

*The Front.*—Having thus put together the main framework of our porch, we will consider how the front is filled in. Between the two collar-posts, at each side, it will be seen that the space is closely filled up halfway—that is, to a height of 3 ft. In the first place, we take a piece of quartered stuff and nail it from post to post, one of its sawn sides being outwards and in a line with the middles of the two posts, and the other sawn side upwards and 14 in. from the ground. To the former side will be nailed the pieces of half stuff seen in Fig. 1, which form the outer side of the wall, and on the latter will rest the end of the board which forms the seat. The upright pieces of half stuff mentioned above are 2 ft. long, and on their tops another cross-piece of quartered stuff (shown in Fig. 1) is fixed, and nailed down into them. Other upright pieces of half stuff, so arranged as to "break joint," are nailed against these from within, both above and below the seat; and the diagonal pieces seen outside (Fig. 1) are again nailed against these latter. Above comes some open work, which explains itself, and at top is a little more solid work—viz., four or five horizontal pieces of round stuff, of which the ends are cut to clip the posts somewhat as those in Fig. 4.

Above the lintel, it will be seen that the gable is filled with open trellis. The little quatrefoils seen in this are made by nailing short bits of rod, with their ends to the front, at the intersections of the smaller members of the trellis.

*The Ends.*—The construction of the ends, as regards their lower and upper parts, is much the same as that of the sides of the front. There is a cross-piece for the seat, and the space beneath is filled by a double row of upright halved stuff; but here we have the closed work rising higher than at the front—namely, 4 ft.—in order that the heads of those sitting within may not be exposed to draughts. Fig. 3 shows the inner side of one end. Here the seat-board, which will be some 14 in. wide, is supposed to be seen fixed, and its edge is ornamented with short strips of split rod. To fix these last securely, a slip of lath should be nailed along below the front edge of the seat-board; the strips can then be bradded to this, as well as to the edge itself. Above the seat, and below the open work, is a large space to be filled with rustic mosaic, to the given design. The cross and upright pieces which form the panels in this are of constructive value, as keeping in place the pieces of half stuff which form the outer wall. In the panels light and dark rods may be used in contrast, the St. Andrew's crosses being of peeled willow, and the filling-in of hazel, birch, or the like, with the bark on.

If, as in this rough work is pretty sure to be the case, chinks should show where they ought not, they can be made air-tight by neatly stuffing with moss.

*The Roof.*—Passing to the roof, it must be observed that its under side—the ceiling, so to speak—is of rustic mosaic; the design for it is given in Fig. 5. In outdoor carpentry there is no prettier work than fitting together rustic mosaic, but it is not so if it has to be done overhead. It is better, therefore, to arrange boards to cover one side of the roof, to screw them temporarily together with ledgers on the off side, and to brad the mosaic upon them before they are fixed up. To the backs of these boards the roof proper, which is of zinc or galvanised iron, will be screwed down.

A metal roof has been introduced, because of the greater facility with which such a roof can be applied by the amateur builder, and not that metal roofs are in other respects things to be desired. They are the reverse of ornamental, and are far too effective as conductors of heat. I have, therefore, taken precautions both to disguise the present one and to keep it cool. Fig. 1 shows a trellis thrown over it, so that it may be hidden and shaded by climbing plants. If brought close to metal, and the aspect is a warm one, climbing plants will not thrive; this trellis is, therefore, kept 4 in. or 5 in. above the roof. Fig. 6 is an oblique section showing how the trellis is fixed over the true roof: *e* is the true rafter; *f* is one of the short pieces of rod which support the false rafter *g*; and it will be seen that these pieces are nailed to the *front* of the true rafter and to the *back* of the false one. The front of the trellis, therefore, projects beyond the roof, and is, in consequence, more effective. At its back the trellis is supported on rafters of half stuff nailed to the wall.

## CONSTRUCTIVE STRENGTH IN METAL WORK.

BY J. WHITFIELD HARLAND.

STRENGTH OBTAINED BY FORM ONLY—CAST-IRON COLUMNS — BEAMS — GIRDERS — "FISH-BELLIED" GIRDERS—T SECTION—DOUBLE-FLANGE HOLES IN WEB OF CAST GIRDERS—TESTING GIRDERS—FRAMING FOR MACHINE TOOLS—SECTION THEREOF — BOSSES OR LUGS FOR LONGITUDINAL TIE RODS—"A" FORM OF SUPPORT—LATHE BEDS—SHARP INNER ANGLES PRODUCTIVE OF FRACTURE—OBVIATING THIS.

IN a former paper I said that the further consideration of this subject divided itself into two distinct classifications: the first involving strength obtained by form only, the other obtaining strength from aggregating separate parts in a constructive manner; and it is the former class that I now propose to describe.

In the construction of buildings, bridges, etc., the replacement of wooden beams, formerly used almost universally, by the use of cast or wrought-iron ones has caused the fullest inquiry and experiment on the part of engineers, and whilst the result has been the compilation of tables of strength of both and formulæ for calculating the required dimensions to carry the necessary weight, and for ascertaining the direction and force of the strains it will be subjected to, it has also led to various theories as to the strongest possible form or shape of material for the purpose in view, and to the economy of weight, and therefore value. Hence it is now recognised that a hollow cast-iron column is able to bear a heavier perpendicular pressure than the same quantity of metal if cast solid; and as columns are intended entirely to support weight, and are not subject to side thrusts, the result has been that cast-iron columns are the rule. It would be expeusive to make wrought-iron columns tubular, and the expense would be unnecessary, as, with the exceptiou of a fire taking place, cast columns are just as good, and at one-third the cost.

In beams—or, as they are called when made in iron, girders—the strain is no longer vertical, *i.e.*, compressive, but deflective or tensile, the whole superincumbent weight being supported at the ends where the girder rests on either walls or columns, as the case may be. Its breaking weight in the centre can be accurately ascertained from formulæ and tables, and the point of fracture will naturally be exactly in the centre, if the weight be at all evenly distributed. On this account the form of the girder known as the "fish-belly" is designed, in which the top flange is straight, whilst the under edge of the web takes the form of an inverted arch, so that at the centre of the girder the depth is considerably more than at the ends. Virtually the metal is taken away from the part where it is not needed, and placed where the breakage would be certain to take place, so as to strengthen such part by economical distribution of the same weight of metal in a more scientific form (see Fig. 1). Here the dotted line shows the original straight girder, and the curved line the "fish-belly" or inverted arch.

It is not only in the length and depth of a girder that difference of form produces extra strength, but also in the breadth, or, as it is generally termed, the "section." Thus the T section, as shown in Fig. 2, can readily be either rolled in wrought iron or cast in metal, and the flange thus formed keeps the web from buckling and overcomes side thrust, besides giving a broader flat surface at the top upon which to lay joists, etc. Sometimes a second though smaller flange is made at the bottom also (see Fig. 3), upon the upper edge of which the ends of joists abut, so that their upper edges and that of the top flange are flush, or nearly so.

Sometimes, especially in bridges, the girder is formed of either one arch-shaped segment or of several segments flanged at the joints and bolted together to form one arch, butting against the springers of the piers, and sometimes cast girders are straight and level at the top flange, whilst the web is, instead of being of inverted arch-shape, latticed and pierced, the bottom flange being really an arch pure and simple, and such girders are in wide spans made in several separate segments and bolted together through flanges at their ends. Girders of wrought iron, on this principle, come under the second classification above-mentioned, as do roofs. There is one point in respect to cast-iron girders that should not be lost sight of, viz., that when necessary to strut them apart, it is very bad construction to drill holes in the web itself. The effect of a hole in the web of a girder weakens it in this way: that the forces are by it divided (as the draft in a flue is divided by a slate put edgeways across) into two directions. The weight upon the top then uses the part of the web above the hole as a fulcrum to tear the part below the hole asunder; whilst the depression or side thrust (acting downwards in this case) has only that depth of the web above the hole to resist it instead of the whole depth of the web. Thus the web is attacked in two directions by opposite forces—one tensile, tearing at the lower part, and the other at right angles as a side thrust; and it will be seen that even a small hole, by its dire consequences in thus dividing opposing forces, weakens the web by very nearly one-half, if the hole be central. The nearer the hole to either flange the less dangerous it becomes, because either the upper part of the web is greater, and therefore better able to support the thrust, and at the same time less able to act as a fulcrum, whilst the lower intact part of the web is reduced so as to be subject only to the partial tensile strain (the rest of such being neutralised by the rest of the down-thrust); or, the hole being nearer to the top

flange, the upper part is less, and therefore the lower part is the greater and the better able to resist tensile strains. At the same time, whilst the fulcrum, it must be admitted, is better, yet the amount of increased cohesion below is so much greater to overcome than before, that the down-thrust loses, in antagonism with the balance or rest of the tensile strain, much of the power it would have were the hole in the centre, so that it is nearly neutralised. Still, a hole anywhere weakens the web; and what is more curious, and almost seems paradoxical, is the fact that two holes in the proper places do not weaken it so much as one in the centre of it. The reason is this: that all space between the two holes is neutral territory where the forces spend their energies in counteracting one another; it is only that below the lower hole that is subject to the undivided force of tensile strain, and that above the higher hole that has to resist the undiverted down-thrust. I am not going now into the method of ascertaining the exact value in pounds of such strains, but they can be ascertained; all I attempt is to point out their existence, and to deduce the inference that, to bolt any strut to a cast-iron girder, holes should be bored in the flanges in preference to the web. It is also evident that if a hole bored on purpose right through may so weaken a girder, that a blow-hole might exist, invisible from the sides, which would weaken it almost as much. Therefore, every girder ought to be tested up to at least two-thirds of its intended breaking strain, which is usually three times that of the maximum load it is intended to carry.

Leaving girders, let us glance at the construction of what is termed the framing of machines and tools, as to the form which gives the greatest amount of strength, and also confers the quality of rigidity—a most essential point. It ought scarcely to be necessary to point out that in order that any machine may work well it must be placed on a perfectly level foundation or floor; if this be not done, all sorts of twists and strains are created, and the journals and shafts work at very great loss through extra friction. In such machines as have horizontal beds, such as lathes, printing presses, planing machines, shaping machines, saw benches, etc., the bed should be dead level both transversely and longitudinally, and the feet it stands upon should, moreover, be placed on an equally level foundation, so that the weight be evenly distributed equally amongst all the supports. The broader the base the lower the centre of gravity will fall, and the more stability will be obtained; at the same time forces will be carried harmlessly away to the earth. The ends, therefore, of a lathe-bed are usually made in the form of a capital letter A (see Fig. 4), which not only is broad at the base, but also, by being bridged across by a rail which is both tie and strut at the same time, affords a solid bearing for a pedestal to be fixed in which the crank shaft revolves. For extra strengthening of this support it is most often made of the section of a double-flanged T girder—*i.e.*, consists of a web and flanges (see Fig. 5)—this form being strong in proportion to the weight of metal used. Upon this flange at the top is fixed the bed itself, and it is often strengthened by longitudinal wrought-iron bars. Too often these are put through the web itself, but in good construction either the web is thicknessed out by having a boss cast upon it or a lug is cast on the outer flange for this purpose (see A and B, Fig. 4), bored, and the rod turned true to fit, and screwed for a nut to force it up to a shoulder forged on the rod (see Fig. 6).

By using the "A" form of support, in which both legs are of the same length, it follows that the contracting in their cooling will be equal, and the after expansion and contraction from changes of temperature will be equal in both and act at the same angle, as also at each end, so that the level of the bed will never be disturbed either lengthways or crosswise—a most important point, as has been shown above, the true working of the tool depending upon it. In a lathe, in order to prevent the bed deflecting out of the straight line—or, rather, plane—of its upper surface, its two parts are cast fish-bellied underneath, as the slightest springiness would be fatal to the work intended to be done. In very long beds, intermediate supports are even requisite, so as to reduce the span between the supports at the two ends.

By a glance at Fig. 2, section of a T girder, at c, c, it will be seen that these angles are rounded off, not left square and sharp. The reason for this is that much extra strength with very little extra metal is gained. Were they allowed to go sharp and square at the shoulder, they would help the forces in certain directions to break the flange away from the web; but this slight rounding obviates this, and the tendency that all sharp inner angles have to go farther, like a crack or the beginning of a crack, is overcome.

In the construction of surfaced bed-plates for all tools, whether shaping machines, planing machines, printing presses or machines, surface plates, drilling machines, saw benches, and the like, where absolute rigidity is a *sine quâ non*—a required necessity—one has to consider the best means of

Fig. 10.

attaining this attribute by the form given to the metal, for they are almost without exception cast. Taking the square or, more often still, the oblong form of table or bed-plate—usually supported at the corners or all along the sides—experiment teaches us that diagonals drawn from each corner, crossing in the centre (and thereby giving the centre), show us the weakest point in any plate of even thickness throughout—viz., that centre which, under pressure, sustains the full brunt of all opposing forces. To avoid thickening the plate out until it shall be strong enough everywhere to enable the centre to resist the opposing forces, which would entail putting metal where it was, not only not required at all, but which would also throw in an attraction to the forces evolved, absolutely weakening the centre (by putting more weight of metal at the extremities of the plane), the principle of the fish-bellied girder is logically resorted to. In Figs. 7 and 9 (the underside, or plan, looking up) I show two forms of this application: the one, Fig. 7, showing webs or ribs running parallel to the four sides of the table intersecting at the diagonals; the other, Fig. 9, diagonal webs intersecting at the centre. A combination of these two forms with slight modifications is probably the best form of construction, especially where very great strength is required—but an illustration of it is scarcely needed. Note always that internal angles of intersection should be rounded into one another and never left sharp (see Fig. 2, c, c), as also where they die into the underside of the plate itself. Fig. 8 is a section through *a b*, Fig. 7. Fig. 10 is a section through *a b*, Fig. 9.

Having thus explained the reasons for the most usual and ordinary methods of gaining strength by form only, I must leave the rest of the subject for another paper.

## EAR-RINGS AND OTHER ORNAMENTS FOR THE EAR.

### PRINCIPALLY WITH REFERENCE TO THEIR MODES OF ATTACHMENT.

BY H. S. GOLDSMITH.

### Joint Hooks — Ear-Studs — Ear-Rings for Unpierced Ears.

Joint Hooks—Rules for Joint Hooks—Stops—Patent Spring Ear-Ring Joint—French Mode of fixing Ear-Top—Ear-Studs—Modes of Retaining Ear-Studs—Spring Pieces—American Spring Piece—German Hook—Details of German Hook—Fastenings and Modes of Attachment for Unpierced Ears.

*Joint Hooks.*—Joint hooks, such as Fig. 18, A, B, were formerly used here in England to a much greater extent; in fact, most of the jewellery made more than forty years ago will be found to have this class of fastening, and even at the present time the French use it a great deal. We find, whenever we examine their work, that the hooks are of a proper shape, and in addition, they have made the fastening into a nicely-formed lip piece, which acts as a guide to lead the wire into the hole, whose edge retains the hook in its place. It is sketched in Fig. 18, B.

Just a word about the proper shape spoken of above. This hook is governed by the same rules as the ear-wire, and *must* be brought well forward if the work is to hang properly.

It is because these are generally bought ready made, and are put on to the work in the shape they then are, that we so often see English-made collet ear-rings hanging down like Fig. 18, C, instead of like Fig. 18, A and B. These last two *could* not hang very much out, while the other one is sure not to hang properly for the whole of its natural life.

Some of this class of fastening (now mostly seen in museums and collections) have the hook and its catch-piece straight up and down, like Fig. 19, A and B, and yet there is nothing wrong with them when in the ear, for the tilting forward is prevented by some arrangement or stop. These stops are generally small, like Fig. 19, A and B; but now and then we meet with a wire mount, devised to keep the ear-top in its place. The arrangement is large enough to rest against the firm cartilage of the ear. The pair sketched here, which are really rather larger than the diagram shows, point out very unmistakably this way of keeping the ear-top in its place, and that is why both right and left are shown in both back and side views.

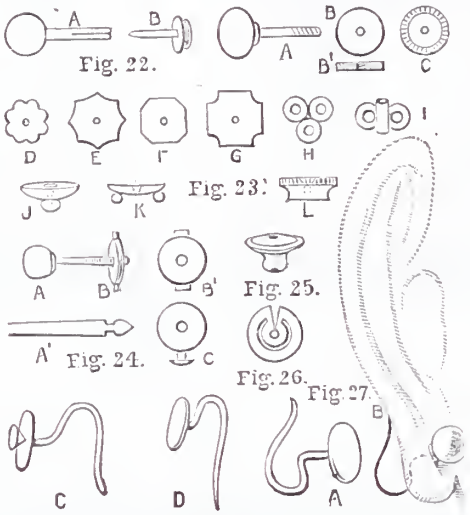

Fig. 22.—Ear-Stud Split Tube (A) and Plug Fastening (B).

Fig. 26.—Form of simple Spring Back to fasten on Plain Wire, made from a piece of fla. Plate pierced as Diagram.
Fig. 27.—German Hooks—A, Correct Form; B, Correct Position in the Ear; C and D, Incorrect Forms of same.

If ends ever do justify the means taken to attain them, then these clumsy ways may be justified, for they certainly succeed in keeping the front of the ear-top *to* the front, and that is one of our chief ends that we must always keep in view and attain, somehow or other. But, after all, would it not be much easier to have the wire of a proper curve whenever we can, so as to bring it into conformity with the remainder of our work, which we take pains to make neat and nice? Not only would it be a saving of trouble, but it would be the best way, because of its suitability and of its simplicity; and in our trade, as in all others, good work shows no effect of labour or worry, but simply seems to have grown like it is, and then it possesses some of the qualities of beauty as defined by Ralph Waldo Emerson, who writes:—"We ascribe beauty to that which is simple, which has no superfluous parts, which exactly answers its end, which stands related to all things, which is the means of many extremes." And in the same essay on Beauty he quotes Michael Angelo: "It (beauty) is a purgation of superfluities."

There is no doubt that stop pieces are necessary under some conditions; but unless such conditions obtain, let us never use ugly arrangements like these except when other and neater methods are not available. Similar to the foregoing, but acting differently, are those sketched in Fig. 20 and Fig. 21.

Fig. 20 is the patent spring ear-ring joint, of which Messrs. Calipé, Dettmar, & Co., 19, Poland Street, Loudon, W., are the sole agents.

The diagrams Fig. 20, A and B, are copied from their handbill; Fig. 20, B, is the form in which they are sold ready for soldering on, Fig. 20, A, being the complete article, the limits of the spring action being shown by the dotted lines. The principle on which this is made seems a good one, for the hook is a fixture, being hard-soldered on, thereby lessening the chance of losing the ornament even if the spring failed to act. The movable or spring piece has no strain on it, and that is, of course, an advantage in favour of security.

Another way of fixing an ear-top is shown in Fig. 21. It fastens in this way:—First the straight piece that passes through the ear is soldered on in a slightly downward direction, and is flattened and notched as sketched. Then the jointed piece is pierced with an oval hole to allow the notched end to pass through until it clips down, and thus it is secured. For both of these we are indebted to the French.

*Ear-Studs.*—Ear-studs are those ornaments which rest on the lobe of the ear, for I have for my present purpose defined ear-rings as the ornaments that hang below it.

To achieve the proper position of this class it is a necessity that the piece of tube or wire that actually rests in the thickness of the lobe should be straight, and should have the ornament fixed on its end, just the same as a brass-headed picture nail has the head fixed on.

This straight piece is the real difference between ear-studs and ear-rings, and in the diagrams, be they screws, pegs, or the German ear-wire, we find the same straight piece; and in the latter it will help us to get the right shape if it can only be understood that in the thickness of the lobe of the ear the straight piece should go, for it is not a hook to be used as we use an ordinary ear-ring hook, as you will see when you get to the details of this a little further on.

Generally, these ear-studs are retained on the ear by one of three methods—first, by pegs, like Fig. 22; secondly, by screws and nuts, Fig. 23, A to L; thirdly, by a spring piece to clasp the wire, like Fig. 25, or to fasten on the end of it, like Fig. 24.

The mode of fastening by a peg, or plug, can be judged from Fig. 22, A and B. It is merely a thin, unsoldered, or split tube for the front piece, which passes through the ear from front to back, and when in position the back plate B (which has a peg soldered on it) is inserted, and, if properly made, holds well. The only two things to see to are—first, that the split chenier is made of rather thin (say size 2 Shakespeare gauge), tough gold, and that the peg fits rather tight.

Those fastened with screws are now the most often made, and after the fashion of Fig. 23, A to L. The other way of screwing the back into the chenier seems to have been dropped entirely. If it were made, the two pieces would be just like Fig. 22 in appearance, but then the chenier would be soldered and tapped to take the peg, which would also be given a screw thread so as to screw in.

Fig. 23 shows that the wire which passes through the ear is screwed at the end, and on this screwed part a nut is made to run. Here are a few shapes that I have taken note of, some drawn in plan, some as seen from the side. They are all in use and all act pretty well, but the best are those which have a good thickness for the screw, like Fig. 23, I, J, K, L, for here we not only get a steady-running nut, and one that will wear well, but we have the chance of bevelling the hole on its top edge, and so be able to lead the end of the screw more easily into its place. Ever such a little bevel is better than none, for we know that ladies have to fumble about behind their ears to get these nuts on.

Spring pieces (Fig. 24, A, B, and C), that clip the bulb-like end of the wire (Fig. 24, A), do not seem to have given universal satisfaction, for between the two evils of a clumsy wire that will give a good grip to the spring, and a neat wire that will pass through the ear nicely, but is too thin to give good hold, no means seem yet to be devised, unless Fig. 25 should be the one. Both (Fig. 24, A, B, and C) act by pressing the thumb-piece in when the wire is to be released, and they both fasten automatically when the beaded end of the wire is placed in the hole made to receive it.

Fig. 25, of which better things are expected, is an American invention, and Messrs. Calipé, Dettmar, & Co., of Poland Street, London, W., are the patentees here.

The wire needs no preparation or alteration ; it simply must be straight and smooth. Then the fastener is made so that it will slide easily up the wire, and will remain and hold just where it is placed, until the bottom bead is caught hold of; then it comes away easily enough. This is a great advantage if the wear and tear of use do not find out defects. There have been a few attempts to use the plain wire and something to grip it. Fig. 26 shows one, but if successful ones have been previously made they have not come under the notice of the writer.

The description of the interior of Fig. 24, B and C, will be given in a paper yet to be written on spring fastenings employed in jewellery.

The so-called German hook, Fig 27, is one of the best, if not the very best, arrangements we have for an ear-stud. It has no loose nut or spring to get lost, and is formed from a simple piece of wire, usually bent as sketched, Fig. 27, A, and worn as sketched in Fig. 27, B.

Now, to make this properly, there are about four things to remember, apart from the quality of the wire, which must not be too soft.

Fig. 18.

Fig. 20.—A, French Spring Fastening: limit of action shown by dotted lines; B, Form as made and sold, ready for dividing and soldering on.

Fig. 21.—Another French form of jointed Ear-Wire.

*First.* The part that rests *in* the ear must be straight, and at right angles with the front of the stud.

*Second.* This part must be just a shade longer than the average thickness of an ear, not much longer, and certainly not shorter.

*Third.* As to the shape of the whole wire, it must be that of a curve, which will permit of easy insertion and withdrawal, subject to the

*Fourth* detail, which is that the very end has to be in line with the front of the bottom loop, so as to steady itself against the back of the ear.

The simplest form is shown correctly bent and inserted in Fig. 27, A and B. These two should be contrasted with C and D, both of which are wrong, and both are prevalent forms of this hook.

Fig. 27, C, is turned wrong way about, to start with, and if worn as an ordinary ear-wire, the front would hang face downwards ; if worn in the proper way, the end is much too far away and will not touch the ear, as it should do.

Fig. 27, D, is but a bad ear-ring hook, and possesses all the defects of that class—which has already been spoken of—and possesses none of the advantages of the German hook. This form of hook, or something that is intended for it, is much used, for we find it attached to the costly diamond or pearl, as well as to the faceted steel and common silver so much affected by the linen-draper jewellers.

**Methods of Attaching Ear-rings to Unpierced Ears.**—With an account of fastenings for ear-rings for ears not pierced, these papers on ear-rings and their fastenings will be brought to a close; for the present, at any rate. And although the writer hopes he has been able to give a little information on the subject, he is by no means confident that he has written a perfect and complete paper, his own opinion being that many good methods have not been spoken of ; but the few he has dealt with are those in every-day use, and, after all, they are likely to be the most useful to the junior members of the trade generally.

Hitherto we have attached the ornament by means of a wire of some shape or other, which passed through a hole in the lobe of the ear. Now we have to find some other way, for that road, we will suppose, is entirely blocked for us. And the wire, which was of necessity continuous when passing through the ear, now must be divided at the top where the ear goes, and the ends so obtained must be made to catch the ear, and hold the ear in between them. Nipping the ear is really what is done, but don't tell the ladies that ; say the ear-ring is secured, clasped, clipped, sprung on or held by gentle but yet firm measures. Say anything that may seem most suitable, so that you do not convey to their mind the idea of possible pain. For the fastenings should be quite painless, as the blunted or enlarged ends give a gentle pressure, and these are by the screw arrangement so easily and exactly regulated, until just sufficient hold is obtained for all reasonable purposes. The writer's definition of "reasonable purpose" is, that there is plenty of grip to hold the ear-ring *itself*. These sort of fastenings can all be pulled off, but they are safe enough to carry the weight of the ear-rings, and the pressure of an ounce or two besides, and that ought to be enough for us.

If greater security than this is required, then the

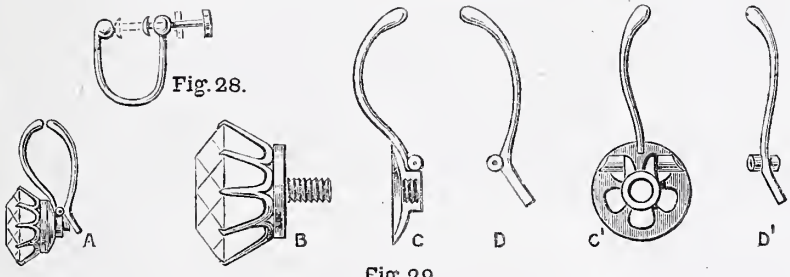

Fig. 28.

Fig 29.

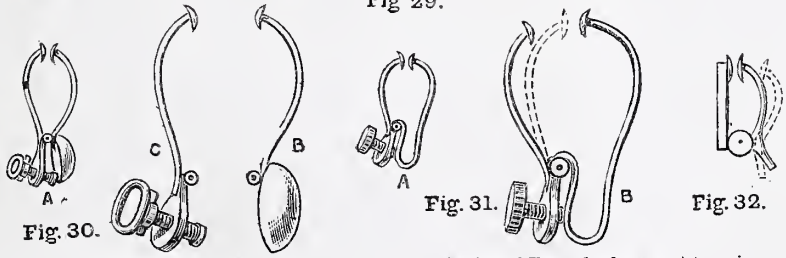

Fig. 30. Fig. 31. Fig. 32.

Fig. 28.—Simplest method of attaching an Ear-Ring to Unpierced Ears, the Ornament to swing or be soldered on to the Front.

Fig. 29.—A, Ordinary size and general appearance of Ear-Ring fastened from the Front; B, Enlarged Front of A, to act as handle to the Screw fixed to it; C, Shows Socket for Screw to work in in Section, and also where the Wire and part of the Joint is soldered; C', Back View of same, showing position of Socket-Joint and Wire; also showing how it can be pierced when the Stone is to be set à jour or transparent; D, Back Wire, with the other part of Joint to hinge to Fig. 28, C. This is the piece that actually nips the Ear, for the Screw acting on its lower end will regulate the position of the upper end.

Fig. 30.—A, General appearance and size of Ear-Ring fastened from the Back; B, Enlarged Front of same, with Joint and Ear-Wire soldered in Position; C, Back Wire and Mount which hinges on to B. This carries the Screw which governs the distance between the ends at the top; it also shows a small Collar or Stop soldered on to prevent loss of Screw.

Fig. 31.—A, Wire Mount for a taching a Drop, actual size; B, The same enlarged, shown open. By the aid of dotted lines it is also shown closed, the principle on which this acts being the same as Figs. 28 and 29.

Fig. 32.—Spring Fastening, acting as shown by the dotted lines: the front straight piece is left for the attachment of an Ornament.

pressure brought to bear will have to be much increased, or the ear must be pierced, and one or other of the previously described methods should be used.

Four out of the five diagrams have a screw for the acting power, and this is preferred for the reasons given above. If a spring is used in any other form, then there comes in the difficulty of always keeping it at a proper pressure, for if it is too great it will hurt the wearer, and if too little, then the whole affair drops off. These remarks apply generally to fastenings whose security depends on the proper action of a spring; not to the one sketched in particular, for that is a good form to use, if we elect to use springs at all.

The method common to all has been given above, viz., nipping the ear in between two ends; and, for the purpose of removal or attachment, one end is made movable either by a spring or a screw.

The simplest is given in Fig. 28; it explains its action clearly by the dotted lines; it is but a U-shape wire. To one end is attached a nut, in which a screw works, and the end of the screw which is blunted is made to approach or recede from the other end (also blunted) of the U-shape wire by simply rotating the screw, whose other end is enlarged, for the purpose of giving a better hold to the fingers. This is but a form of ear-ring wire, and to it an ornament has to be attached, or swing, before it is an ear-ring, properly so-called.

In the next two, Fig. 29, A, and Fig. 30, A, there is a greater resemblance to the ordinary wire, and they can be formed into ornamental ear-tops as ear-tops are usually made.

The desired result in these wires is obtained in a somewhat different way, and the next three diagrams, Figs. 29, 30, and 31, show that one part of the wire is *fixed* to the front of the ear-top, while the other (back) part of the wire is jointed to it in such a way that enough opening is obtained between the ends to let the ear pass, and so that a screw, acting on the lower part of the same jointed wire, will cause the upper end to approach the end of the fixed front wire. And it is in between these ends that the ear is nipped. After all, the diagrams, and the descriptions on them, will doubtless do more in the way of explanation than several paragraphs.

Fig. 29, A, Fig. 30 A, Fig. 31, A, are all about the size they should be made; but as it was impossible to in any way show the details in drawings of that size, the whole of the parts have been enlarged.

The reader will not require to be told that the coronet setting, with its open or skeleton back, of Fig. 29, and the plain dome of Fig. 30, are not at all necessary parts of these fastenings, for there is no reason at all against the employment of the coronet (without a screw, of course), as the front of Fig. 30; or on the other hand, if we should require a plain gold front to Fig. 29 in place of the coronet setting, we can use a plain gold front as a thumb-screw just as well. Or we could have a smaller centre on the dome, and make that act as the means to turn the screw. The principle upon which all these act is such a simple one that there should not be the slightest difficulty in adapting one or other of these to our work, be it ever so much unlike the few that are given here.

Fig. 31 is but an alternative form of wire to Fig. 28, and is here given principally for the purpose of showing the action which is common to the two previous ones.

This action is of the simplest description, and we should clearly understand that all we require is: first, to separate the ends for the lobe of ear to be inserted, which the untwisting of the screw allows; secondly, to cause these ends to approach each other, and be retained in the approved position, and this is managed as is clearly shown, it is hoped, by the diagram and by what is written above.

Simply moving the one end in the same line is all that is asked for; therefore, no lateral play is required, and there must be none, else the ear will not be properly clasped. In plain, workmanlike phrase, the joint should fit, and should not depend on the joint pin for its correct position, as too many joints are made to do, not only in such things as this, but in many other joints used in every-day work. But that is the refrain of a song that will always come into the writer's head, for he is in the workshop all day, and is always meeting with such small annoying details, which cause irritating delays, for generally the workman can do them all right at a second attempt, and should do them at a first, but he does not.

When we have room enough, a small collar or washer should be soldered on the top of the screw, for the purpose of preventing its withdrawal from the screw socket in which it works, for then it cannot be lost. It is shown in Fig. 30, C, and need be very small, for it has but to just *not* go through the female screw.

In Fig. 29, we use the front as a handle to turn the screw with, but in Figs. 30 and 31 we have handles expressly made. Now, of these, there are but two kinds, namely, fixed and jointed. Fig. 30 gives the simplest form of jointed, and Fig. 31 a simple specimen of the fixed form. Something must be drawn to show a complete article, so these two are selected, not that they should be always followed, for they can easily be made more ornamental; and if they are, see that the form selected combines neatness with unlikeliness of catching the lace or other material that ladies wear, and that, above all, the handle should be easily grasped when the screw has to be turned.

Fig. 32 is a spring fastening, made by the firm previously spoken of (Calipé, Dettmar, and Co.). The spring is contained in the hinge, and the limit of its action is shown in the diagram. This more nearly approaches an ear-stud in appearance, for the front straight bar is intended to have an ornament fixed on it, and is made of hollow wire for that purpose.

## FILLERS IN FRENCH POLISHING.

BY DAVID DENNING.

Object of Fillers—Choice of Filler—Filling with Polish — Pumice-Powder — Tallow Filler—Water in Filler—Oil and Polish — Turpentine and Whiting Filler — Colouring Fillers—Patent Fillers.

Anyone who has applied French polish, or even thicker varnish, to wood must have noticed that it sinks in or is absorbed, instead of remaining on the surface in a thin uniform coat. I say uniform, because here and there it will be observed that the polish or varnish has given more gloss than elsewhere. Where the gloss is brightest the varnish has sunk least. Those who know why size is used in painting or coarse varnishing will understand me when I say that fillers are used by French polishers for much the same reason—viz., to prevent immoderate absorption of the polish by the wood. That the grain may be filled up by going over the wood with polish till the pores are closed cannot be denied, and some beginners may want to know why anything else in the nature of a filler should be used. The reason is simply that the comparatively valuable French polish need not be used instead of a cheaper material, by the use of which, moreover, time is also saved. Some woods, being more open in the grain and porous than others, stand in special need of a filler, while with some fine close-grained woods fillers may be almost dispensed with. I do not, however, know that they—or rather, I should say, a suitable one—can do any harm to any kind of wood, so that, however fine the grain of this may be, there can be no disadvantage in going over it with a filler preparatory to polishing. At the worst, it may be a slight waste of time, and there are polishers who occasionally dispense with any filler except a preliminary rub over with polish when working on a fine wood such as olive, which those who have used it know is both close and hard. As in every other operation, in polishing opinions differ as to the best way of attaining the desired result—viz., the production of a thin glossy film of shellac, which shall not be liable to grow dull unreasonably soon. Some of the processes and methods of manipulation savour strongly of empiricism, so that, without advising the novice to use some particular filler with some particular kind of wood, and none at all with others, it will be more to his advantage to recommend him to use a filler whenever he thinks that by so doing he can save time and material. It may, however, be said that the woods ordinarily used in furniture—ash, oak, mahogany, walnut, etc.—certainly should have the grain filled. After what has been said, the reason for this is obvious, for they are all of comparatively open grain, ash and oak especially being coarse.

Now, when so many different kinds of fillers are used, and each has its advocates, I do not consider it would be fair to readers simply to mention the one I prefer, and claim for it all good qualities, while denying them to others which I may not so much approve of. It will be much better to name the principal fillers used in the trade, and make a few remarks about each, so that learners can experiment with them, and perhaps finally fix on that which may seem to suit them best. In any case, they will find them all reliable, for good work is turned out by polishers with any of them. Naturally, the man who has confined himself principally to one filler is more at home with it than with others; but, unless he is an extremely prejudiced individual, he would hesitate to say that the others are all bad. He uses the one which suits him best, that is all. Mind, it is not even said that he uses the one which he thinks is the best; for sometimes, owing to the great question of price, he may be impelled to use the easiest and quickest, irrespective of its quality. This, perhaps, is not as it should be, and the amateur, at any rate, will be free to follow his own fancy.

The first filler that will occur to one is varnish, or extra thick polish, rubbed into the wood till the pores are full. This is a clean and natural filler, but unfortunately it is a troublesome one, and the results are little, if any, better than those arrived at by a cheaper and more expeditious method. It is, however, easy to conceive that occasionally it may be an advantage to proceed with this, though, if he is doing it for trade

purposes and at trade prices, he will find that on ordinary furniture he is "out" by employing it. Briefly stated, the process is simply rubbing in polish or thin varnish, and when it is dry smoothing down with the finest glass-paper. The application of polish and paper must alternate till the former no longer sinks, and this will depend altogether on the nature of the wood and the material used. With fine, close-grained, hard wood, the process will be much more expeditious than with a coarse open one, such as ash.

A modification of this direct filling with polish is effected by the use of fine pumice-powder, which not only renders the process quicker, but better. I believe this method is more practised in France than in this country, where, though it is sometimes employed by the trade, it has not been anything like generally adopted. Apart from the time required with it, it is doubtful if any better means of filling the grain has been discovered, for it is both clean and free from greasiness. Those who wish to try it may proceed as follows, adopting such modifications as may seem advisable. As before, polish is the basis of the filler, the pumice-powder being useful not only in assisting to fill by getting into the pores of the wood, but in rubbing down inequalities of the polish. The powder is kept in a muslin bag, and lightly sprinkled on the wood, which is then gone over with an ordinary polish rubber fairly charged with polish. Only a small quantity of the pumice-powder should be used at a time, as if in excess, the work suffers. Instead of sprinkling the powder on the wood, some polishers prefer to put it on the sole of the rubber. The work will require papering down afterwards, whichever method be adopted, but perhaps not to the same extent as when the pumice-powder has not been used.

A filler that is very much used is composed of Russian tallow, mixed with either plaster of Paris or whiting; and I fear the chief thing that can be said in its favour is that it is a quick process, and therefore allows of polishing being done at a comparatively small cost for labour. Tallow is not, however, a nice material to work with, for reasons which will be readily understood. Apart from its unpleasantness, tallow is apt to increase the tendency of the polished wood to sweat, from the grease breaking through the film of lac. In saying this, I am aware that I am laying myself open to contradiction from many experienced French polishers who use no other filler than the one now referred to; but there can be no doubt that oil or grease, in connection with polish, can, at the best, only be regarded as a necessary evil. As there are fillers in which there is no grease, it is just as well to use them, even if, to avoid discussion, it is admitted that a "tallow filler" is not prejudicial to good work or to durability.

The tallow and plaster are made into a stiffish paste and well rubbed into the wood, from which any excess must be wiped off; and, to avoid repetition, the same remark applies also to the following fillers. Any that set hard must be wiped off while the filling is still soft.

But it may be asked whether, if grease is objectionable, water cannot be used instead, to render the plaster or whiting soft and pasty? It may be, and often is; but then, one objection is that the water is apt to raise the grain of the wood, which I suppose all readers know means making it rough. Of course, the surface can be rubbed down smooth with fine glass-paper, but then, tallow does not raise the wood at all. Still, whiting, or plaster of Paris and water, do not form by any means a bad filler, and, personally, I much prefer this mixture to any in which tallow or grease is found.

As tallow is unpleasant stuff, many polishers discard it in favour of oil (raw linseed), with some polish mixed with it. By the use of this with whiting, the objection to water is overcome, but it is not altogether a suitable filler for the novice. If he errs by having too much oil, the sweating already alluded to is apt to take place at no distant day; while if he uses too much polish in the mixture, the filling is apt to remain on the surface instead of being forced into the pores of the wood. It is, however, unfortunately not possible to give proportions of oil and polish which shall be suitable on all occasions, so that the polisher must use his own discretion. If he does not feel up to this exertion, he may as well leave this filler alone till he has acquired some experience, but in capable hands it is a really good one.

For a good general filler—in fact, the one which I consider the best—I do not know of one to beat whiting and turpentine. It is both clean and economical, does not raise the grain as when water is used, and it contains no grease. Those who have followed me will thus see that it is not open to the objections which are urged against other fillers, and, from personal experience, I can recommend it to all and sundry. I can certainly say, if they do not succeed with it, that the fault does not lie with the filler, and that they are not likely to succeed with any other. Another advantage it possesses over plaster of Paris and water is that it does not harden so quickly—some, indeed, urge that it does not harden sufficiently—but this objection cannot be treated as a serious one, or founded on practical experience. Let the mixture be in the form of a stiffish paste, but still thin enough to be worked into the wood, and no difficulty ought to occur.

It is advisable, if not absolutely necessary, that this, as well as other white fillers, should be tinted to correspond to some extent with the colour of the wood on which they are used. The following colours will be some guide to the novice, and it may be remarked that the polisher will seldom have occasion to use any other in his fillers: for mahogany, rose-pink; walnut, or any brown wood, such as stained oak, Vandyke brown; and for ebonised work, gas-black, are as good as any. Light woods, of course, may have the filler applied *au naturel*; but if it should be deemed advisable to tint it, there will be no difficulty in doing so, as an exact match is not necessary.

In addition to these, the ordinary fillers of the British workshop, there are several patent and American fillers which may be used by those who like them; but I do not think that any of them have ever come into general use, or are likely to supersede the commoner varieties. A common complaint among polishers against them is that they are more expensive than these, without having sufficient compensating advantages. I do not, however, wish to prejudice readers of WORK against any form of filler that may be introduced to their notice; but, at the same time, I cannot recommend any of those I have tried as being much, if at all, superior, for general purposes, to a good home-made filler, properly used. I do not affirm they are worse, and they may be as good, or even better; but I must say that I am inclined to be sceptical whenever I see the great advantages which are sometimes claimed for new preparations—a scepticism which may possibly be attributed to prejudice. Well, perhaps it may be, but at any rate it is a prejudice which I am quite willing to have removed whenever I can find a filler, clean, thorough, expeditious, and as cheap as any of those I have named. If any *professional* French polisher uses such a one, and can speak from his own experience of it for two or three years, perhaps he will kindly name it for the benefit of readers of WORK. A mere trial or experiment is not sufficient, hence my reference in the last sentence to professional polishers.

## THE SAFETY BICYCLE: ITS PRACTICAL CONSTRUCTION, ETC.

BY A. S. P.

DRAWING-BOARD—LINE DIAGRAM—RAKE OF STEERING—L-PIN—STEERING BARREL AND HANDLE-BAR ADJUSTMENT—BOTTOM BRACKET—TUBES AND MUD-GUARDS—STEEL CASTINGS—PATTERNS—CENTRE STEERING—DETAILS OF BOTTOM BRACKET—ADJUSTMENT SCREWS—DETAILS OF STEERING BARREL—DETAILS OF L-PIN SOCKET—MATERIALS, HUBS, AND FITTINGS.

BEFORE beginning the construction of our safety bicycle, we must provide ourselves with the materials, and our first step in practical progress is to make a full-size drawing of the machine, either on a large sheet of paper mounted on a board, or on the board itself, which is on the whole preferable.

The board must not be less than 4 ft. long and 3 ft. 6 in. broad. It should be planed clean and smooth, and have the near edge made quite straight. Proceed by laying down two 30 in. circles, 12 in. apart. Of course, only a part of each circle will be on the board, it being too short to hold the whole, but it is sufficient if the hubs are shown on the board. In the absence of beam compasses, use a thin wood lath. Make two holes in the lath, 15 in. apart—one hole for a bradawl or a nail, the other to let through the point of a pencil. Make two marks for the bradawl on the board, 15 in. from the near edge—which we will call the ground-line—and 42 in. apart, and from these points draw the two circles, which will each touch the edge of the board, or ground-line.

Now, with the line diagram before you which accompanies the second paper of this series, proceed to lay down the various lines as therein shown. In that diagram (Fig. 2, p. 100) we have A, A, the two wheels; call A, on the left, the steering, or front wheel. From C, in its centre, let fall the vertical line to D. Next draw a line parallel to the ground-line, and 12 in. above it, joining the two circles, as shown by a dotted line in the diagram. Divide the dotted line into four equal parts, and at 3 place the centre of the bottom bracket or pedal shaft, marked B on the diagram. From B raise a vertical line, which will touch the nose of the saddle on the one hand, and the rear end of the handles on the other. Now, in order to find the rake of the front steering tube, you draw the line E F from the centre of the rear circle or wheel to a point 4 in. above the periphery of the front wheel. Now, from C to O draw a line 3 in. long; then from D, on the ground-line, mark off towards H 4½ in.; from H draw line H G through O. This will be the centre line of rake. For the machine with curved fork, the curve of the fork ending at C C, 3 in. in advance of O, this line, if correctly drawn, will be found to form a right angle

with the line E F. Now, to find the true position of the L-pin socket, draw a line to the right of, parallel to and 3 in. from, the line rising from B. Mark off on this line the top of the socket, 30 in. from the ground-line. The complete socket, as shown in Fig. 1 (p. 33), may now be drawn, showing the attachments for the various tubes.

Now, turning to the fore-part of the machine, we have the barrel J (Fig. 1). This is drawn on the line G H; it is 6 in. long and 1¾ in. thick in the body. The drawn in, with its mud-guard and stays; also the spoon of the brake, with the hingeing pin which passes through the sides of the fork, 1 in. above the rubber of the wheel.

The bottom bracket has now to be indicated. In our design it is a fork having the chain wheel inside, and the two bearings close to the cranks, which makes by far the best bottom bracket. Further on, details of this fork will be given; meantime, it is only necessary, in preparing the full-size draw- cross-piece on their forward ends for bolting on to the back edges of the bottom bracket fork. The pair of tubes, F, enter sockets at the top, and on the tenons of the small rear stampings. The diameters of all these tubes are given in a former paper. The bent tube, D, which follows the curve of the wheel rim till within 3 in. of the top of the bracket fork, is about 1¼ in. clear of the rubber tyre; to the back of this tube is bolted the rear mud-guard. This guard has two pairs of stays, and is consequently sup-

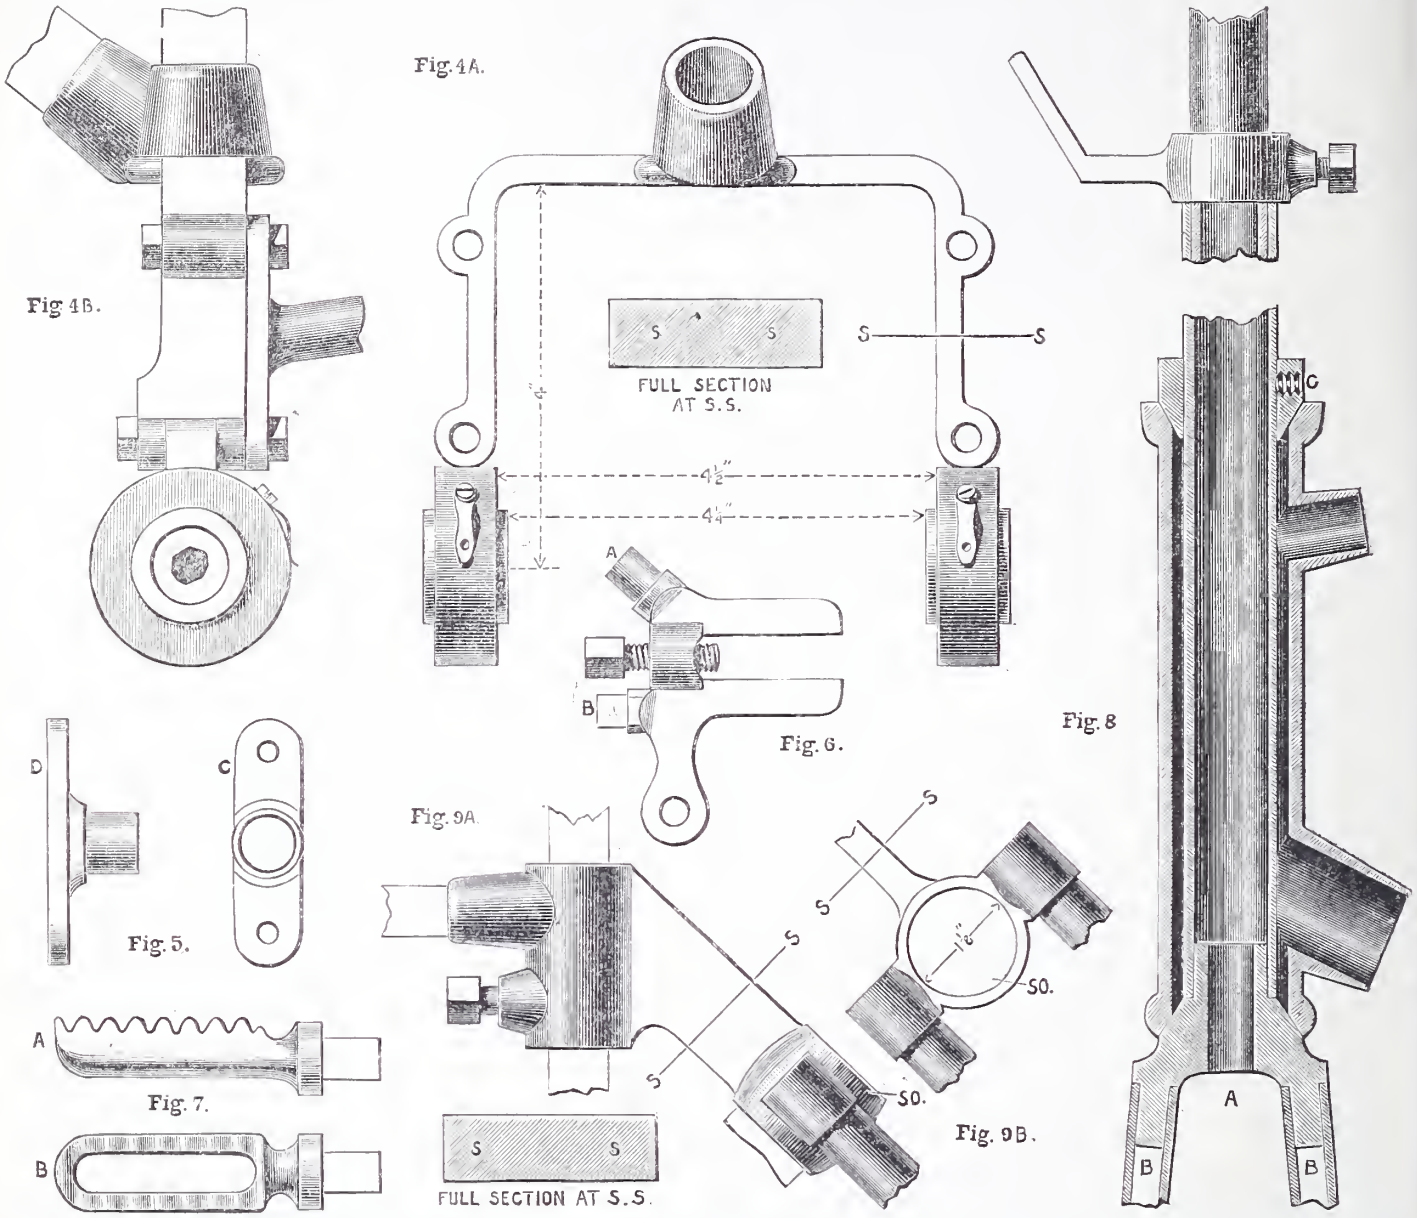

Fig. 4 A.—Bottom Bracket Fork. Fig. 4 B.—Ditto, Side View. Fig. 5.—T-Piece showing Face (C) and Edge (D). Fig. 6.—Rear Fork Stamping. Fig. 7.—Mounting-Step, in Side View (A) and Plan (B). Fig. 8.—Section of Steering Head or Barrel. Fig. 9 A.—Connection of Upper Tubes of Frame (Side View). Fig. 9 B.—Ditto, Plan. The above figures are all half full size.

position of the lower end of the barrel is 2 in. above the periphery of the wheel. The barrel should be drawn in section, showing the 1 in. tube passing up from the fork crown to the clamping ring. The full length of this inch tube, G, is 11 in. The handle-bar adjustment tube, K, which is 8 in. long and ⅞ in. diameter, may also be shown in section. On the barrel, J, should be drawn the two sockets for the tubes B and C, having their centres on the lines P, P, in Fig. 2. The socket for tube B is 1⅛ in. inside, and that for tube C ⅞ in. inside measure. The front fork should now be ing, to show the side of the bracket fork, as in Fig. 1, with a knuckle-joint ball-bearing fitted in. The socket for the lower end of tube B is 4 in. above the centre of the pedal shaft; from this point the bent tube, D, is drawn, from the top of the bracket to the L-pin stamping; M, radius from the centre of wheel at F. The small forked stampings that carry the rear wheel axle usually have tenons (not sockets) that enter the tubes. When this part is put down in the drawing, the lengths of the various tubes may be readily found, allowing 1 in. of tube to enter all sockets. The pair of tubes, E, have a ported at four points. I prefer the two stays, because I notice constantly that a badly-supported mud-guard sags in the middle.

There are but two stampings or castings in the frame here shown that cannot be bought in the market—namely, the bottom bracket fork and the L-pin stamping. These I get made (together with all my solid parts, in fact), cast from patterns, in malleable steel. The barrel, J, can be had in the market, fitted with balls. In the present case, however, we will show it as a cone-steering arrangement.

To those who do not care about making patterns for any part, stampings for all the parts may be bought. This would, however, involve a slight alteration in the design of the frame, particularly at the junction of the various tubes with the seat socket. But anyone laying down the full-size drawing, by observing strictly the positions shown in Fig. 2, and after drawing the stampings in their proper places, can set the various tubes with them.

Then, again, some might prefer the open centre-steering arrangement, which has the turning centres about 1½ in. behind the centre of steering tube. In this case two lugs are brazed on to the steering tube, about 4 in. apart, the lower one being immediately over the crown of the fork, and the upper one having a set or head-screw, with lock-nut for steering adjustment. All the parts for this arrangement may be readily purchased. The firms where to purchase, and the prices of the parts as near as they can be ascertained, will be given at the end of this paper.

Fig. 4A and Fig. 4B are half-size drawings of the bottom bracket fork, A being the front view and B the side, showing the attachment of the forward end of one of the lower tubes from rear of frame. In Fig. 4A, the width of the fork, as well as the height from the dotted line passing through the centre of the bearings, are indicated. A full-size section of the fork (S S) is given, the lower forked ends being broadened out to receive $\frac{5}{16}$ in. holes, to bolt in the knuckles of the bearings. The sockets for the main tubes are placed on the centre of the fork, that for the tube D being vertical with the arms of the fork, the other, for the main or backbone tube, going off at an angle, which can be readily determined from the full-size drawing. They run into each other, and are reamed out for 1⅛ in. tube, the vertical socket going quite through, the other running into it. The tubes should go at least an inch into the sockets. On the back of Fig. 4B will be seen the T-piece of the rear tube. It is a steel casting 2½ in. long, ⅝ in. broad, and ¼ in. thick, with a tenon on the back to enter the tube; it is bolted through the bracket at its upper end, and the lower end is held by the bolt that passes through the knuckle of the bearing.

This T-piece is shown half-size at Fig. 5, C, (face) and Fig. 5, D (edge). Two of them, of course, go to the one machine.

Fig. 6 is the rear fork stamping, which carries the rear axle; it has the two tenons for the tubes. The screw for adjusting the chain is also shown; the shank of the screw is square, and may be turned for adjustment by a small key. In the figure shown there is a descending projection for the mounting-step; the other, of the pair, would be on the right side of the machine and without the descending piece, the mounting-step being always on the left. The step itself may be either rubber on a steel pin, or a piece of hollow serrated steel, like Fig. 7.

Now we come to an important part of our machine, the steering head or barrel. Fig. 8 is a section of this barrel in half-size. As will be seen, the bearing parts are cones, not balls. To those who would prefer a ball-head, I should refer them to No. 92, Vol. II., of Work, where a ball-head is illustrated and described in answer to a correspondent. In our head (Fig. 8), the two ends of the barrel are coned to an angle of about 30 degrees; the top of the fork crown is coned to the same angle, while for the upper end of the barrel a coned ring is made. This fits easily on the steering tube, and is set in its place by a set-screw, passing through the side and pressing on the steering tube. The figure shows the sockets for the tubes, and the proper angle in making the pattern is found from the full-size drawing.

We now come to that part (Figs. 9A and 9B) which connects the upper tubes of the frame and contains the L-pin. This also is a steel casting from a pattern. The vertical part is that which is bored for the L-pin, ⅝ in. thick, of round steel. The part behind the L-pin socket fails away at the angle of the two tubes which descend to the rear axle. At S S a section of this part is shown full size. The part marked S O is the socket to receive the bent tube D, 1⅛ in. thick; on each side of S O is an eye or socket to receive the rear tubes above mentioned. The tubes are not brazed into these eyes, but merely fitted, and set-screws inserted through the side of the eye and into the tube. When these screws are removed, and the bolts at the bottom bracket, the hinder half of the frame comes away. The L-pin socket has on the front of it a socket to receive the ⅝ in. upper tube, C, corresponding in size to the upper socket on the barrel (Fig. 8). Beneath this socket is a ⅝ in. snug, which is bored and screwed for a set-screw to fix the L-pin. This casting is over all 4½ in. long. The small bracket which clamps the saddle-spring to the L-pin is bought ready made, and need not be described here.

Having described most of the parts, we have now to consider where they are to be procured, and at what price.

I may state, first of all, that steel castings cost from 6d. to 8d. per pound, and that there are from 5 lb. to 6 lb. in the machine. The whole tubes can be bought for 7s. 6d. Front forks, brazed, per pair, 1s. 3d.; weldless steel, per pair, 3s. 3d. Handle-bar tube, 2s. 6d. Full set break-work, 2s. 9d. in the rough. Pair mud-guards, 9d.; mud-guard stays, per pair 9d.; 30 in. by ¾ in. crescent steel rims, 3s.

Now as to the parts that may be bought finished.

We have first a pair of ball hubs, bored for spokes, tapped and plated, from 16s. to 24s. A pair of Bown's ball bearings, for bottom bracket, 11s. Chain wheel, sixteen teeth, 2s. 4 ft. Abingdon Humber chain, 6s. Cranks, rough, 1s. 2d.; finished, 4s. Pedals, ball, from 9s. 6d; plain, from 5s. (both plated). 3-coil spring, 2s. Long-distance saddle, 4s. 6d.; or saddle and spring combined, much superior, from 7s. 6d. to 15s. Handles (horn, rubber, or cork), from 2s. 6d. a pair.

Now as to the firms where these things can be procured, I have found the following to be good houses:—

Wm. Bown, 308, Summer Lane, Birmingham.

Thomas Smith & Son, Saltley Mills, Birmingham.

W. A. Lloyd & Co., Clyde Works, Birmingham.

Henry Matthews, Snow Hill, Birmingham.

Brown Brothers, 7, Great Eastern Street, London.

St. George's Cycle Company, London.

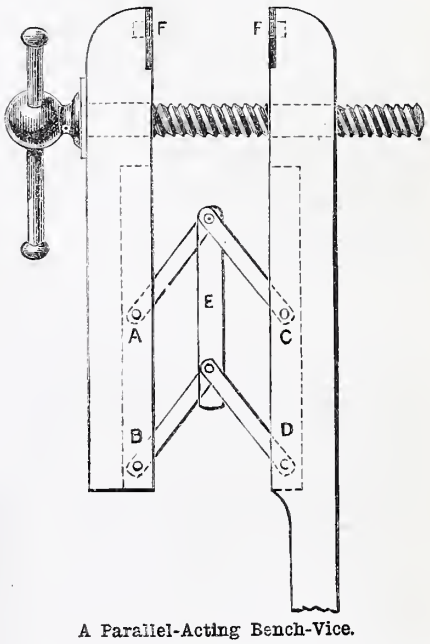
It would be needless to enumerate more, as anyone of the above will supply almost everything required, and will readily send their catalogues and price-lists to anyone writing for them. They will also supply rubber tyres at from 2s. 6d. to 7s. 6d. per lb. Considerable changes have been made in the form of tyres during the last year or two, but with this I have nothing to do at present. I am merely showing the reader where parts of bicycles may be purchased.

## A PARALLEL-ACTING BENCH-VICE.

BY J. CHARLES KING.

All contrivances to economise time and trouble in every-day shop work mark the impatience naturally felt at work that is irksome, producing nothing by its action, simply regulating other actions of tools. This must have been felt by wood-workers with the ordinary vice fixed at the back ends of benches.

The smiths have long used parallel vices, and know their merit. The cabinet-makers' and the coachmakers' vice in general use is something like the accompanying illustration, but it has a regulating blade at the bottom of the shifting jaw, which moves in and out of a mortise in the fixed jaw—parallel with the vice screw. It has a number of ⅜ in. holes in its length for an iron pin to be put in every time the work that is gripped varies with opening of the jaws. This little job of pinning and unpinning and repinning to widths of stuff to be gripped wastes a woodman's time



A Parallel-Acting Bench-Vice.

materially. If there is much vice work, two or three days in a year—half a week's work—are wasted, and nothing to show for it at the year's end.

If you are careless about pinning the vice parallel, the jaws do not grip properly, the work is held insecurely, and the screw worn out by unfair strain on the threads; and the process, after all, is one of guesswork as to what will be parallel. An automatic parallel adjustment is shown applied to the ordinary woodman's vice with wooden jaws, the action of compound levers from fixed points in the jaws effecting this to any width opening of the vice. There are nine light blades of iron. A, B, C, and D are four points for fixing double blades of iron 1⅛ in. by $\frac{3}{16}$ in. These, it will be seen, point upward, and are held to an upright blade, E (1⅛ in. and $\frac{3}{16}$ in.), all the parts being truly adjusted for lengths. When the vice jaws are closed, these blades shut up into recesses boxed out of the wood of the vice jaws shown by dotted outlines. The length of the blades may be: for upright piece 10 in., for diagonal pieces 8 in. The middle blade is, of course, held between the double diagonal blades by rivets

admitting of free movement of parts jointed together.

Why these compound levers should produce a parallel action, and set and rigid fixture of the jaws, however tightly they are screwed, may amuse some young workman to investigate.

A useful contrivance for gripping bolts and flanged iron or brass-work, is to have the iron plates of the jaws and part of the wood mortised out, as shown at F, F. It serves also to hold set-pieces of rubber or leather, used for galling-pieces.

## OUR GUIDE TO GOOD THINGS.

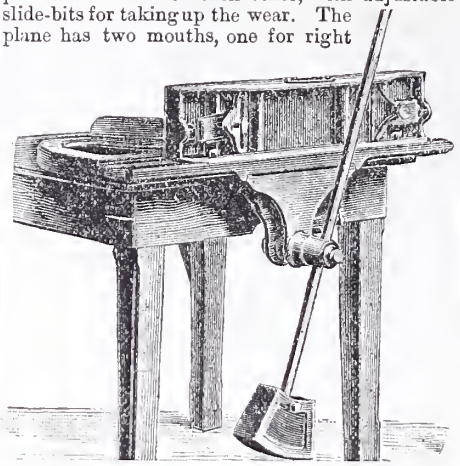
**** Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of Work for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of Work without charge, the notices given partake in no way of the nature of advertisements.*

22.—"The Machinery Market and Exporter."

Occasionally a Part of this publication reaches me, and this I am bound to acknowledge. It is published monthly at 6d., at 181, Queen Victoria Street, E.C. It has been in existence more than twelve years. It should be seen by all who are interested in machinery. In addition to information of a trade and practical character to be gathered from this journal, much is to be gleaned from its advertising pages, of which there are about seventy in the journal proper and its monthly supplement.

23.—Hutchens's New Patent Mitre Machine —the "Eclipse."

Some account of this excellent machine, whose inventor and patentee is Mr. William Hutchens, 70, Causewayhead, Penzance, was given in page 9 of this volume of Work, with working drawings in plan, end elevation, and front sectional elevation, and to these the reader is referred for details of the construction of the machine, of which a general view, showing how it may be fixed for use, is shown in the illustration given herewith. The machine is made in two sizes—namely, with shoot 6 in. by 3 in., and 10 in. by 5 in.; and each size has two different forms of construction — namely, with fixed and adjustable angle-plates, the machines of the smaller size being known as machines A and C, sold at £5 and £5 10s. respectively; those of the larger size, designated machines B and D, being supplied at £6 10s. and £7 respectively. Agencies and depôts for the sale of the machine, and where it is on view, have been established in London, and the great manufacturing towns of England and Scotland; and although it is not possible to give a complete list of them here, readers may obtain a prospectus giving this information from the patentee, and it may be useful to add that in London the machine may be seen at the establishments of A. C. Engert & Co., 75, City Road, and W. H. Oxenford, 51, Lowth Road, Camberwell. The patentee is constantly receiving most satisfactory testimonials, as a labour-saving machine that is easily worked, and does its work well, from picture-frame makers, carvers and gilders, and cabinet-makers, who all agree that "the machine works so easily, and cuts the moulding so sweetly, that it changes a usually disagreeable and laborious job into a pleasure, which is added to by the accuracy with which it is found the mouldings are cut." In the fixed patterns—that is to say, the A and B machines—the angle guide for the mouldings is fitted so as to be perfectly square, and firmly fastened at an angle of 45° to the plane face. In the C and D machines it has a very simple and secure adjustment by which the angle can be varied from 45° to 90°; in these machines the bed-plate is divided into degrees, and the guide has a finger-point to set it to whatever angle is required. The bed-plate and plane are of iron, each accurately planed and fitted to each other, with adjustable slide-bits for taking up the wear. The plane has two mouths, one for right



Hutchens s New Patent Mitre Shooting Machine —the "Eclipse."

and the other for left-hand mitres, so that the machine is always ready for either. The arrangement for adjusting, taking out, replacing and fixing the irons is at once simple, expeditious, and effective. The toothed quadrant actuating the plane is firmly keyed on a turned wrought spill, through which the lever of polished steel passes, leaving a wood handle at the upper end, and a balance weight at the lower end, which brings the machine in position and gives a saving to the cut.

24.—Machine-Cut Diamond Pattern Lumber.

Possibly some intelligent reader, who is only acquainted with the word "lumber" in the sense in which it is commonly used in this country, may think that I am going somewhat out of my way in talking about such stuff here, so I may facilitate matters by explaining that in the United States the term "lumber" is applied indiscriminately to all kinds of timber sawed or split for use, as beams, joists, boards, planks, staves, hoops, and the like, and, in the present case, to boards with a worked surface for decorative purposes. The engravings, Figs. 1 and 2, show the "Machine-cut Diamond Pattern Lumber"; the former in plan, and as viewed from above, and the latter in end view. Moreover, they show the exact size of the diamonds, and are therefore to be regarded as full-size patterns. "This stuff," says the card from which the illustrations are copied, "is made by a special machine invented by us"—the "us" being the Brown Bess Manufacturing Company, Clinton and Jackson Street, Chicago, U.S., according to my informant—"the *only* machine of its kind, and each piece will match *perfectly* with all other pieces, by 'jointing' the edges to the centre, lengthwise, of any row of diamonds. *Size* of each piece, 8 ft. long by 6 in. wide and ½ in. thick. *Price* 10 cents (about 5d.) per *running* foot of 6 in. in width, *net cash;* crated and delivered f. o. b. (free on board) Chicago, in orders of not less than 6 pieces. *Send for Sample.*" I have been particular in sticking to the text of the card, because my correspondent, Mr. Jas. Rollison, Armstrong, Kansas, U.S., evidently thinks it a big thing in wood-working, asking, as he does, on the card: "Can they (*i.e.*, British workmen) make it over there (*i.e.*, in the United Kingdom) and keep up with Yankees?" (This, please note, is Mr. Rollison's term, not mine.) His letter, which accompanied the card, runs thus:—"Mr. Editor, I send you this card to show you the latest Yankee notion in wood-working, as your paper is considerable in that line. I thought you might give it to some wood-working establishment and let them try to make such. If I were nearer to you I would send you a sample. I am not much of a scholar, but you must excuse me. I will send a sketch of a very useful wood article in course of time. Some of your wood-workers can make it easy. I do not want to see the English mechanic dropping behind; but in some things they are. I receive some stray numbers of Work out here. It has a good variety in it." Well, Mr. Rollison, we are agreed in wishing to see the English mechanic still to the front, and hence the existence of Work. I gladly introduce a reproduction of the card you send, partly in acknowledgment of your thoughtful kindness in doing so, and partly for the benefit of chip-carvers, who may like to work the pattern on facias, uprights, rails, edges of shelves, etc. There is not the slightest difficulty in contriving a machine to work the surface as shown in Fig. 1, for its principle lies in sending a shallow V-tool, whose edges are inclined to one another at a wide angle across the surface of the wood, first in one direction and then in another, thus making V-shaped grooves, which are inclined at the same angle to the edge of the wood under treatment. Apply this principle to a machine in which a number of V-tools of the same size and pattern move in parallel lines, and you get directly at the method in which the work is done. Similar patterns in a variety of designs might be made by altering the angle of inclination of the grooves to the edge of the wood, or by leaving an interval between each cutting tool.

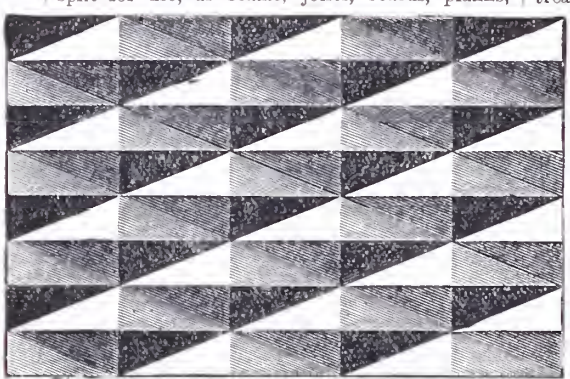


Fig. 1.

Fig. 2.

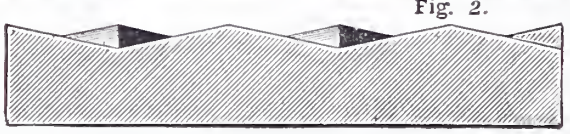

Fig. 1.—Machine-Cut Diamond Pattern Lumber, shown in Plan and as viewed from above. Fig. 2.—End View of ditto.

25. — Atkinson's Linesman's Galvanometer.

Electric bell, telephone, and telegraph linesmen, who are not overburdened with a surplus of cash, will be glad to know where to get a galvanometer or current detecter at a low price. A very useful linesman's galvanometer is made by Mr. H. Atkinson, 137, Stamford Road, Handsworth, Birmingham, and sold by him at the modest price of half a guinea. As it measures only 3½ by 3 by 2 in., it may be said to be a pocket galvanometer; but it is by no means a toy. The outer case is of teak, well jointed and polished. The dial is of brass, on a blackened background, and is enclosed in a thick bevelled glass frame. The coil is mounted on ebonite supports fixed to a brass plate, and all the mountings are of strong polished brass. The needle is of the dead beat type, soon coming to rest when the instrument is disconnected, thus rendering it valuable for detecting leakages in line wires, and testing the condition of battery cells.

I can recommend this neat and nicely-made instrument to such of the readers of Work who may require such an appliance, as it is not only effective, but cheap also, as may be judged from the comparatively low price that is asked for it.

The Editor.

## SHOP:

### A Corner for Those who Want to Talk It.

*** *In consequence of the great pressure upon the "Shop" columns of* Work, *contributors are requested to be brief and concise in all future questions and replies.*

*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* Work *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

### II.—Questions Answered by Editor and Staff.

**Bricks.**—Penybryn.—Without any particulars or idea of your proposed method, it is difficult to give you a definite reply, but as a user of bricks for more than twenty years, I may say that unless your plan is cheaper and stronger than ordinary bricks, you will have a difficulty in getting it introduced. Many kinds of patent bricks have been brought out, but during last year I visited many buildings in various towns in this country and abroad, and did not see any of them in use. There is often a difficulty in getting the ends jointed properly, and if your plan involves any extra work at this point, the walling will cost more. The quality of the mortar has much to do with the strength. I have seen walls thrown down which fell in a solid mass, and in which the bricks were separated from the mortar joints with great difficulty; while in other cases the bricks have come quite clean from the joints when thrown down. Nevertheless, if you can make them, and they can be walled as cheaply and are stronger than ordinary bricks, there is no reason why you should not patent your idea. You must first ascertain whether your idea has been previously patented; and if not, get provisional protection for nine months, during which time you can bring them out, and see how they are taken up, before going to the expense of a patent. You will get much valuable information on taking out a patent in Vol. I. of Work; or if you like to send me particulars and a stamped envelope through our Editor, I will tell you if your idea is practical. I will promise you not to make use of or disclose your idea.—M.

**Repairing Old Chair.**—C. J. W. (*Brecknock Road*).—To soften the glue in order to take the chair partially to pieces, would not be the plan usually adopted by a cabinet-maker.. If it is imperative for you to soften the glue, it must be done with moisture and heat. It will be a very tedious job if it is practicable—and this I am inclined to doubt. Any way, it is hardly likely to be worth the trouble. Your best plan will be to cut through the tenon at the joint with a fine saw. If the tenon is a good one you will have no difficulty in reframing with dowels. Should the tenon prove to be rotten, chisel it out, and fill up the mortise with a sound bit of wood. If the parts are put together neatly, no one will be able to detect that anything has been done, and the frame will be as strong as ever it was. Possibly an expert might be able to manage without taking the frame apart, but without seeing the chair, I am unable to say positively. The plan recommended is thoroughly werkmanlike, and you can hardly adopt a better.—D. D.

**Repairing Veneer.**—C. J. W. (*Brecknock Road*).—Probably the best way to re-lay the broken veneer will be to insert a little hot glue under it. Then press the veneer down, and keep it down by pressure till the glue has set. Read the article, "Hints on Repairing Furniture," page 658, No. 93, Vol. II. of Work.—D. D.

**Use of the Word "Patent."**—R. H. (*Southport*).—Provisional Protection does not entitle you to use the word "Patent" on your articles. You have no legal right to use that word till the patent has actually been granted. If you make use of it before that time, any rival maker who may feel himself aggrieved has power to institute proceedings against you. Still, the thing is not unfrequently done, and the danger of interference in the shape of an action at law is generally very small. But we are bound to warn you that by using it you incur a certain risk.—C. C. C.

**Heat in Perkins' System.**—H. H. (*Cambridge*).—I am not able to give you any definite instances of the occurrences mentioned in my reply to a previous querist on the system of hot water, but a high authority on hot-water work—viz., Chas. Hood, F.R.A.S., F.R.H.S., etc., etc.—speaking of high-pressure systems, after describing them, says:—"The temperature of these pipes when thus arranged can be raised to a very great extent; for being completely closed and all communication with the atmosphere cut off, the heat is not limited as usual to the point of 212°. because the steam which is formed is prevented from escaping, as it does in the common form of hot-water apparatus. The most important consideration respecting it, however, is its safety; for most persons are aware that steam when confined beyond a certain point of tension becomes extremely dangerous, and in this apparatus the bounds of what has hitherto been used in other cases are very far exceeded. . . . The average temperature of these pipes is stated to be generally about 350° of Fahrenheit's thermometer; but a most material difference of temperature occurs in different parts of the apparatus, amounting sometimes to as much as 200° or 300°. This arises from the great resistance which the water meets with in consequence of the extremely small size of the pipe, and also from the great number of bends or angles that occur in order to accumulate a sufficient quantity of pipe. . . . The temperature of the coil, however, is what we must ascertain if we wish to know the pressure the apparatus has to sustain, and thence to judge its safety, for by the fundamental law of the equal pressure of fluids, whatever is the greatest amount of pressure on any part of the apparatus must also be the pressure on every other part. Now, the temperature of this apparatus is found to vary, not only with the intensity of the heat of the furnace, but also with the proportion which the surface of the coil bears to the surface which radiates the heat. In some apparatus, if that part of the pipe which is immediately above the furnace be filed bright, the iron will become straw colour, which proves the temperature to be about 450°. In other instances it will become purple, which shows a temperature of about 530°; while in some cases it will become a full blue colour, which proves then that the temperature is 560°." (Hood on "Warming and Ventilating," pp. 137-8.) Now, even supposing that the pipes only reached to the lowest of these three temperatures—viz., 450°—this would be quite hot enough to scorch textile fabrics *if laid upon it*, or to scorch paper if close to it. But it appears that this is not so much a source of danger as the extremely high pressure which such a heat indicates, for at a temperature of 560° the pressure is 1,150 lbs. per square inch, and with an increase of 50° the pressure is immediately raised to 1,800 lbs.; and a further increase of temperature, 40°, raises the pressure per square inch to 2,800 lbs.; so that any circumstance which causes the fire to burn more briskly than usual may at any moment increase the pressure to an enormous amount. The pipes are stated to be proved to a pressure of nearly 3,000 lbs. per square inch, but as pipes are always proved cold, this does not in any way prove what pressure they will stand when heated; but it is certain that it is nothing nearly so great, iron becoming much weaker as its temperature is raised. Hood further says (pages 146-7):—"This invention undoubtedly exhibits great ingenuity, and could it be rendered safe and its temperature be kept within a moderate limit, it would be an acquisition in many cases, in consequence of its facile mode of adaptation. Its safety would, perhaps, best be accomplished by placing a valve in the expansion pipe, which, from its large size, would be less likely to fail than one inserted in the smaller pipe. If this valve were so contrived as to press with a weight of 135 lbs. per square inch, the temperature of the pipes would not exceed 350° in any part." You will be able by the information now given to examine your pipes, and form an opinion as to sheer safety; probably, the precaution of a safety valve as suggested has been adopted.—R. A.

**French Polishing.**—A. H. (*Maidstone*).—You cannot do better than to read the articles and "Shop" answers on "French Polishing" which have appeared in Work. Consult the Indexes to Vols. I. and II. These will give you more than any book.

**Hardware.**—J. C. (*No Address*).—Obtain as many things as possible from one factor, who would give you very nearly as good terms as the manufacturers (the latter possibly might not care to execute a very small order), and you would save something in carriage if you reside far from London. You could obtain the screws, nails, bolts, and general ironmongery from Messrs. Harding & Sons, Long Lane, London, S.E.; lamps, etc., from Messrs. Falk, Stadelmann, & Co., 43, Farringdon Road, London; oils and colours from Messrs. Chuck, Lockett, & Co., 10, Norton Folgate, London, E.—T. W.

**Lettering on Opal.**—J. B. C. (*Coatbridge*).—This is work executed by means of acids, burning, and other mechanical processes. You will never get any colours to stand unless they have been specially prepared and burnt in at the ornamental glass works. The heat from gas is the cause of the mischief of which you complain. Give the work to a Birmingham firm.—H. L. B.

**Shocking Coil.**—Curious.—I cannot clearly understand the drift of your letter. If you have made some shocking coils in the past, and all these have worked well, I see no reason why the last two should fail in giving similar results. It appears to me, however, from your letter, that you expected to get shocks from the primary wire of your two last coils, and, because you did not get shocks as you expected, you suspect something wrong in the coils. Surely, you did not get shocks from the primary wires of your other coils! If you get more than you can stand out of the secondary coil, that should fully satisfy you. If you put more wire on the secondary coil, as you suggest, the shocks from this will be stronger with the same battery power. Cartridge paper is too thick to use as an insulator between the layers of the coils, and shellac is too stiff. Use instead some foreign post paper steeped in paraffin wax. I do not know anything about the other apparatus mentioned by you. Perhaps it was part of an electrical conjuring trick.—G. E. B.

**Electric Bell Manuals.**—N. B. (*Highgate*).—You will find "Practical Electric Bell Fitting," by Mr. F. C. Allsop, 165, Queen Victoria Street, a useful book. "Electric Bells, and all about them," by T. R. Bottone, may also be useful to you. As you will not be able to localise and repair all defects by reference to books, you will do well to submit your difficulties to us, and get helped out of them through the medium of Work.—G. E. B.

**Bath.**—Windermere.—I see no reason why you should not construct a bath as you suggest, providing you intend doing all the work yourself, for if you have to pay for bending and drilling the iron, rivetting together, etc., you might as well buy a tinned iron one right out. You will have a difficulty in getting a sheet wide enough of the gauge you will require, viz., 22 ft. or 24 ft., as few ironmongers keep sheets of that gauge more than 3 ft. wide. You also speak of giving it a coat of bath enamel; it would require at least three coats to make a good job of it, and four or five would be better still; let each coat get thoroughly hard before applying another. The way you suggest of bringing the water to the boiler is all right; you should also take a branch pipe out of the pipe leading to the boiler to supply the bath with cold water. It is a pity you could not have the bath lower than the boiler (which, from your sketch, I take to be an ordinary washing copper), for then you could have supplied both hot and cold to the bath without having to dip it out, as I presume you intend doing.—R. A.

**Book Edges.**—W. J. J. (*Southwick*).—The reason why your colours sank below the surface of your size may have arisen from various causes, and it would be difficult to tell unless I saw both your colour and your size. However, I suspect it is your colour that is at fault; you say that you used "ordinary colours in powder." Now these may, or may not, be all right. Only vegetable colours can be used for marbling, and they must be very specially ground; there must not be the slightest gritty appearance about them, or they will spread out like powder when thrown upon the size; and when transferred to the edge, they will be extremely faint, which you found. The colours, ready ground, which you ask for can be had from Messrs. Berry and Roberts, St. Bride Street, London, E.C.—G. C.

**Sheet Steel.**—C. E. S. (*Stoke Newington*).—Try Pfeil & Co., John Street, Clerkenwell. They sell excellent steel at moderate prices.—J.

**Horizontal Engine.**—A. W. A. (*Waltham Cross*).—Pocock's "Model Engine Making" is the only book I know of, treating specifically on this subject, but it is very amateurish. Hasluck's "Model Engineers' Handy-book" contains some useful information.—J.

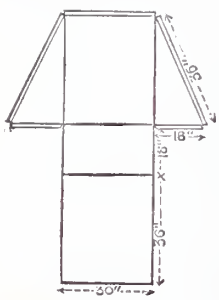
**Paquelin Lamp for Plumbers' Joints.**—Plumber.—The Paquelin lamp is a success for wiping joints. One of our men used it a few days ago for a joint in 2 in. lead pipe for a pump, and also for wiping the joints under a bath, waste, overflow, etc. I cannot understand why you cannot make the metal stick to the pipe. I expect the reason is that you are using too fine a solder, and get it too hot. Use ordinary plumbers' metal, two-thirds lead, one-third tin; get your pipe fairly warm with the lamp before applying the solder, and use the solder in sticks. The stick of solder acts as a spoon to keep the metal up till you have enough on the joint; then, when it is of the right consistency, go round with the cloth. When the joints are not wiped, use coarse tinman's solder.—R. A.

**Inlay and Carpentry.**—A. L. L. (*Farnham*).—Much has appeared in Vols. I. and II. of Work upon these subjects. A reference to the Index of each volume, which can be bought for one penny, will give the numbers and pages of Work.

**Beams and Scales.**—X. Y. (*Leeds*).—A beam constructed as represented in your sketch would be condemned. It would take more time to put right than it would be worth. You do not say if the machine is to rank first, second, or third class. If we take the turning load of a first-class machine as *one*, that of a second-class is *four*, and of a third is *six*. Again, you do not state if the ends of the beam are "swan-neck," "box ends," "Dutch ends," or if it has "agate" or "knife-edge" bearings. "Swan-necks" are discouraged, and will in course of a very few years be disqualified, after sufficient time has been allowed to wear out those at present in use. The friction on such, when worn or badly fitted, is quite sufficient to account for the extra weight you name as required to move it when the scales are hung on. Or, again, the "kuife edges" may be thick, dull, soft, or not straight, or at exact right angles across the beam. The same may be true of the bearings in which the "knife edges" work. Any of these faults would increase the friction, which would be intensified in proportion as the load was increased, and a larger amount of "force" would consequently be required to overcome that friction and cause the beam to oscillate—the "force" being represented by a heavier weight, as in your case: half a pound being required to turn the scales instead of half an ounce. To adjust weights, measures, and weighing machines successfully, a certain amount of "touch" is required that only practice can give. You may learn much about the theory of these matters if you study Ganot's "Natural Philosophy and Physics"; also Grieve's first, second, and third stages of "Elementary Mechanics" (Longmans—1889 editions). Also get a copy of "Model Regulations," 1890, for Inspectors of Weights and Measures (1s. 6d.), and also a copy of "Notices to Candidates" for examination as Inspectors of Weights and Measures (2d.), both

published by Eyre & Spottiswoode. You may then learn what the inspector will require of a machine before he considers himself justified in stamping it as fit for use in trade.—WORKER BEE.

**Lantern Stages—Making Gas Bags and Limes.**—A. E. D. (*South Lambeth*).—I should advise you to read the papers which appeared in WORK, Nos. 83, 87, 91, 96. Full particulars of how to make the slide stages will be found in No. 91; and the addresses of a few firms supplying cheap condensers and objectives have already been given in reply to Opticus, WORK, No. 91, page 633, and also in reply to J. P. (*Blackburn*), WORK, No. 97, p. 733. Should any difficulty occur, write another query, giving full particulars. You also state that you are desirous of making a gas bag, owing to the prohibitive price of this adjunct to a lantern. You will find this a very difficult job, and I have never yet heard of its being successfully accomplished by an amateur, and should certainly not advise you to attempt it. It may be possible for an amateur to repair a gas bag, but the making of a new one is quite a different matter. You do not state the form of jet you intend using. If you intend to employ a safety jet, procure from an indiarubber warehouse some strong twill mackintosh cloth, either check pattern or a brownish-black, which will cost from 3s. 6d. to 4s. 6d. per yard. For an ordinary 10 ft. wedge-shaped bag you will require to cut this to the form indicated in the accompanying diagram, the measurements of each side being 36 in. long, 30 in. wide, with a couple of wedge-shaped sides 18 in. wide at the thick end, with the back of the bag also 18 in. wide. About an inch should be left on all cut sides for turning in and cementing, the cement used being a solution of rubber in benzole; or, better still, a tin of proper cement for indiarubber could be obtained for about 1s. from the tradesman supplying the cloth. An accurately made gas tap will also require to be cemented into the middle of the apex or thin end of the wedge of the bag, in order to provide the means of ingress and egress for the gas. I am very much afraid, however, that you will not be able to make a satisfactory job of it, as professionals use several appliances for making a bag air-tight which it would not pay for an amateur to obtain, especially when you can get a bag ready fitted with a tap for 45s.; this would be an extra strong one, made of three-fold thickness of stuff, and would hold sufficient gas for over two hours' exhibition. It is sold by Messrs Archer & Co., 43, Lord Street, Liverpool. The following are the quotations of a few of the leading firms for a bag of about 10 ft. capacity. It is a difficult matter to give an accurate statement of the exact cubic capacity of a gas bag when filled with gas, as the wedge shape renders them peculiarly liable to bulge outwards, thus rendering it somewhat troublesome to accurately gauge their cubic capacity. A cheap bag, measuring 36 in. × 32 in. × 24 in., is sold by Messrs. Perkin, Son, & Rayment, of Hatton Garden, for 45s.; and Messrs. Noakes & Son, of Nelson St., Greenwich, make a cheap bag 36 in. × 32 in. × 24 in. for 48s.; this can be had in strong white twill for oxygen, and black for hydrogen. Messrs. Humphrey & Co., of Stanhope St., Birmingham, sell a black rubber bag of three-fold thickness, fitted with a padlocked gust tap, and measuring 36 in. × 30 in. × 24 in., 50s.; and Mr. Walter Tylor, of 48, Waterloo Road, S.E., charges 52s. 6d. for a bag of similar dimensions. Messrs. Woods' (74, Cheapside, E.C.) price for a bag 36 in. × 32 in. × 24 in. is 70s.; and 72s. 6d. is asked for a similar sized bag by Messrs. Watson & Sons, of 313, High Holborn. If you simply require the bag for home use, you would find it much more economical to construct a wooden or metal gasometer, or vessel in which to store the gas. In construction these are somewhat similar to the ordinary gasometer of the gas-works, consisting of a cylinder, bottom upwards, sliding within a cylinder, which is filled with water in order to make it gas-tight, the requisite pressure being obtained by means of heavy weights placed upon the top of the inner cylinder or suspended from its sides. With reference to your last question, it is difficult to say how long a lime should last, as so much depends upon the skill of the operator. One operator might use one or two limes during a single entertainment, whilst another exhibitor would find one more than sufficient. With an oxy-calcium jet it is sometimes possible to use a lime a second time, provided that it is kept in a tightly corked bottle away from the atmosphere; but with a mixed jet this cannot be done, as the unused lime will crumble away.—C. A. P.



Gas Bag.

**Bookcase.** — G. H. (*Burton-on-Trent*). — Mr. Adamson gave, some time back, a drawing and a few details of a dwarf bookcase (without doors). Search the indexes. The mortise and tenon joint is the one generally adopted to unite the "cross bars," but halving will be strong enough for the purpose. These two forms of joint have been so frequently described that it is really unnecessary to again sketch them. If I do not note your assertion that although you "are pleased with WORK, but one has to wait such a while for an answer," you may, perhaps, believe that I intentionally disregarded it; therefore I must entreat you to watch and count each week the number of letters acknowledged as received, and then compare them with the number of answered letters which limited available space permits to be printed, and you will—or ought to—understand why *some*—not *all*—queries are held over for a while.—J. S.

**Wood-Carving Tools.**—A. W. A. (*Bilston*).—The tools should be sharpened on the inside, and ground on the outside. The angle should be very acute. It would be a guide if you were to get one properly set by a carver, as you would then know better than by any amount of written description. In case you do not know any good carver, I daresay

Fig. 1. Fig. 2.

Angles for Tool Sharpening.

if you sent a tool to Urquhart & Adamson, 13 & 15, Bold Street, Liverpool, they would do what is necessary for a small sum as a favour, if you mention this Magazine. If you prefer to try for yourself, the illustration (Fig. 1) herewith will give you some idea of the angle to which carving tools should be set, as compared with that of the ordinary chisel (Fig. 2).—D. D.

**Photo Tent.**—R. H. (*Bradford*).—Procure four wooden uprights, ash by preference, 8 ft. 6 in. long and 2¼ in. in diameter, slightly tapered towards one end, and the other pointed and shod with iron to drive into the ground; an iron peg put through the pole just above the shoe, and projecting about 1 in. on each side, will be of assistance in fixing the poles in the ground. Two of these poles are intended for the back of the tent, and should be provided with holes protected with iron plates near the top, so that a roller background can be made to work in them in the usual manner. Into the top of each pole an iron pin is driven, leaving 3 in. projecting, through which a slot is made in order to receive a small pin to secure the whole together when set up. Four rods, either wood or iron, sufficiently long to leave a space of 8 ft. by 6 ft. clear between the uprights, and perforated to fit over the projecting pins at the top of each pole, will keep the framework in position. The distance from front to back should be about 6 ft. The whole arrangement is exceedingly simple, and can be pulled up and rolled together when done with. In use, the canvas covering will be permanent overhead, one or other of the side pieces being open according to the light required. The appearance of such a tent will be, when in use, as accompanying

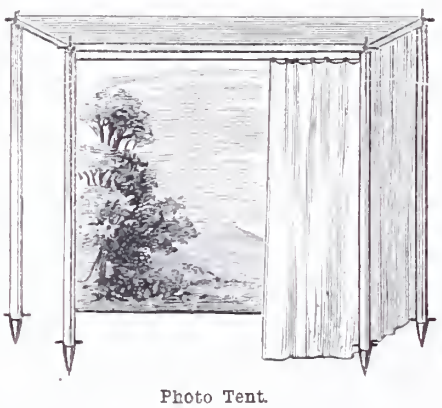


Photo Tent.

diagram. A curtain in front that can be pulled across at will, running easily on a rod, will be found a help in arranging the light. If the rod worked in a socket, so that the curtain could be pulled inwards or outwards as well as across, so much the better.—D.

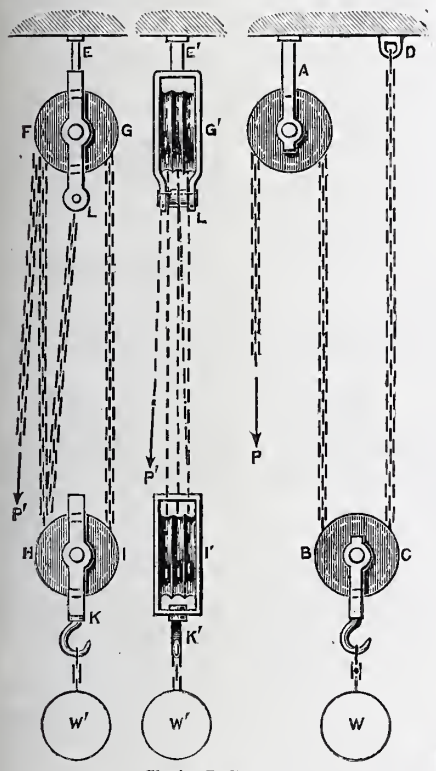
**Carriage Crests and Monograms.**—J. L. G. (*Norwich*).—The method of doing this and the kind of paper used to paint them on is, I believe, a trade secret. They are painted with oil colour on prepared paper. The crests, letters, or ornaments must be, of course, painted on the paper the reverse way, so that when turned over on to the panel, they will transfer right-handed in proper form. The shading of the crest or letters that should show on the face must be painted on the paper first, and the ground colours or gold put on last. Colours are sold ready for use in tubes; if too thick, thin with turpentine. To transfer the painting, you must be careful, and go all over it with gold-size and copal varnish made up in equal parts, taking care to keep well to the outer edge, with a small pencil, or camel's-hair will do. The gold-size and varnish must not be laid on too thickly, but just enough to cover. If the crest or monogram is not properly covered, some of the paint will stick to the panel and the rest draw away with the paper. When the gold-size and varnish is on the "tack"—that is, when it is nearly dry—it is ready to transfer to the panel. The panel should be first "flatted" with pumice-powder, and a pad with water to dull the surface and take the nibs off. Wash off clean, and dry with chamois leather. After getting the centre of the panel, strike with the chalk line a horizontal and a perpendicular line; thus having your chalk line struck, you will find on the back of the transfer a horizontal and perpendicular line crossing at the centre of it, which, when placed on to the panel, must come exactly over the chalk lines; then you will have it exactly square. Take care to exclude any air, and gently rub it with a small piece of cloth, so that all parts may adhere equally. Then with a wet sponge sop the paper until it moves, and gently draw it away. Pat the painting with the sponge wrung dry, wash off, and dry with chamois leather; take care not to rub too hard: and in two hours it will be ready for varnishing all over. Should you desire to varnish sooner, use more gold-size to the varnish that you transfer with; but on no account use gold-size alone, as it will cause the paint to crack and flake off after a while, and your job will be spoilt. There is another kind of transfer which is painted on very thin paper. These are treated in a different way. The back of the paper is done over with gold-size and varnish mixed, and when nearly dry is stuck on the panel; then the whole of the panel is varnished over. But this does not make such a nice job as the process described above, as it always shows a little projecting from the surface; but it is very handy, and always shows right handed—the way it is painted. I tried an experiment the other day which I found answered very well. That is: on a piece of ordinary note-paper I designed a monogram of three letters in lead-pencil, then glazed it over with ordinary gum, which, of course, should be clean and transparent. When dry, I commenced painting in the pencilled letters, which were still visible, beginning first with the shading—of course, the reverse way to that in which I wanted it to show when transferred; finally painting on the ground colour, or laying on the gold or silver leaf last. Thus you will see I have a coat of gum between the monogram and the paper, which, when wetted on the back, moistens the gum; then the paper was drawn away, leaving the monogram on the surface of the panel to which it was to be applied. Crests, ornaments, etc., can be treated in the same manner. These will have to be stuck on with gold-size and varnish mixed, and transferred in the same manner as explained in the beginning. The transfer method of heraldry is a quick and convenient way for some coach-painters and those who do not possess art and skill to paint them direct on to the panel, or wish to send them off by post. In the usual course of direct painting, herald painters first make a "pounce"—that is, they sketch the design on a piece of paper, then prick with a pin or needle all the outlines; next they get the centre of the panel, and strike with thread and chalk—called a chalk line—a perpendicular and horizontal line. They then place the "pounce" on the panel: then with pad—that is, powdered whiting tied up in a piece of fine muslin—they dab lightly the "pounce" or perforated design, then they raise it carefully; that will leave on the panel the outlines of the crest, etc., in white. They then commence to paint in colour to the lines, or size and lay on the gold-leaf and then shade it. Thus, you see, whilst you are painting on the paper to be transferred you could paint direct on to the panel with less trouble and better effect. The heraldic transfer materials can be obtained at Whittingham & Wilkins', Long Acre, W.C., and at Leigh Anderton's, heraldic painter to the trade, 67, Vine Street, Newton Heath, Manchester. By sending stamped envelope, they will forward you list of prices, etc.—C. W.

**Accumulator Cells for Electric Lights.**—J. C. H. (*Dublin*).—The number and size of accumulator cells required for an electric light installation are determined by the following considerations. (1) Volume of current required to light the lamps. (2) E.M.F., or pressure to force the required current through the lamps. (3) The number of hours it is intended to use the cells for lighting the lamps. Considerations 1 and 3 must guide us in the size of the cells, and the number of plates in the cells, as the volume and duration of the current will depend upon the capacity of the cells, it being estimated that 1 sq. ft. of positive plate surface will yield six ampère hours of current. Your ten lamps, of 8 c.p. each lamp, will take 280 volts of current to light them. Twelve lamps will take 336 volts of current. Find out the total resistance of the lamp circuit, employ one cell to each two volts of pressure required, and this will give the number of cells to be employed. Multiply the volts of current by the number of hours the cells are wanted, divide this by the voltage of the cells used, and you will then find the desired capacity of the cells. I think you will need 9 E.P.S. L-type 15-plate cells. These have a larger capacity than the 11-plate and the 7-plate cells. In charging these in series you should employ a current of not less than 10 ampères at a pressure of not less than 20 volts. If you had given me the size and type of your dynamo, I could have told you whether it would be practicable to charge the cells with it or not. Thin plates such as you mention are not safe to make the grids for large cells.—G. E. B.

**Ebony Stain.**—TREACLE PUSHER.—If you are, as your *nom-de-plume* indicates, a polisher, surely you must be aware that home-made black stains are not so good as those which are bought ready made. As you live so close to London, you will be able to buy the stain for little, if any, more than it would cost you to make it, besides getting a better article. If you are determined to try what you can do, I am afraid I cannot recommend anything to surpass the old recipe of a decoction of logwood chips and vinegar in which some steel filings have been left for a time; or, if you prefer to do so, substitute a solution of copperas for the vinegar. Good

proportions are 1 oz. each logwood and copperas in a quart of water. Apply hot. Then go over with the vinegar after the first is dry. Repeat till the stain is dense enough.—D. A.

**Chain Pulleys.**—DIPLOMAS.—Your question is rather vague, but I suppose you wish to know how to calculate the increase of lifting power gained by the use of pulley blocks, and upon this assumption I answer you, using the accompanying diagram to make my remarks clear. In the first place it must be understood that the increase of lifting *force* is gained at the cost of speed, or distance passed through in a given time. Work done is a *force* or *weight* acting through a *distance*, and *work* cannot be increased or diminished by any machine whatever. I shall not consider loss by friction of pulleys, etc., as that would complicate the matter without helping us. Suppose you pull on a chain with a force of 50 lbs., and you pull the end of that chain (keeping the same pull upon it all the time) through a distance of 10 ft. You will then have done work equal to 50 multiplied by 10, equals 500 ft. lbs. Now, if it had been a pull of 10 lbs. through 50 ft., the total work would have been the same, and so the total work may consist of any two numbers representing respectively force and distance travelled; so long as when multiplied together they make 500, the resulting work will be the same. The same argument also applies equally to any other quantity of total work done, but we see that the greater the force



Chain Pulleys.

applied, the less will he the distance passed through, and the less the force, the greater will be the distance passed through. Suppose with a pull of 50 lbs., you want to lift 800 lbs., the pulleys and chains must be so arranged that you pull in 16 ft. of chain, while the weight lifted rises 1 ft.; because 800 lbs. × 1 ft. = 800 ft. lbs., and also 50 lbs. × 16 ft. = 800 ft. lbs. Having described the principle concerned, I will now show the application of it. In the diagram, P indicates a force or pull applied to a chain in the direction of the arrow shown. If the chain merely passed over a fixed pulley at A, and had a weight at its other end, that weight could not exceed P, because in that case the only change which occurs is a change of *direction*, the force P and the weight would travel at the same speed, and neither gain nor loss of power would occur; but if the chain is carried round another pulley, B C, and up to a fixed point, D, and the weight W suspended from the pulley B C, there will be a difference of speed between P and W. The pulley B C rises and falls with the load, and such combinations as these are called blocks and falls, the upper pulley or set of pulleys attached to a fixed point being called the block, and the lower one the fall. Now, to raise the load W one foot, each side of the chain A B and C D must be shortened 1 ft., therefore the chain A B C D must be shortened 2 ft. by pulling that length of chain over pulley A, from which it is evident the force P must move 2 ft., while the weight W moves 1 ft., therefore the weight W may be twice the force P, for if P = 50 lbs., and W = 100 lbs., then 50 × 2 = 100 ft. lbs., and 100 × 1 = 100 ft. lbs. It will be noticed that the load lifted is equal to the lifting force multiplied by the number of lines of chain side by side, the hauling chain P, which is wound to slack, not affecting the result. A side view of a block and fall, carrying three loose pulleys on each, is shown at E, F, G, H, I, K. The top block is fixed at E. The chain passes from P round the top and bottom pulleys successively as shown, and is fastened to the top block at L. A front view is shown at E', G', I', K', and W' is the load to be lifted. It is seen that between the block and fall there are six lines of chain, each of which must be shortened a foot to raise the load W' 1 ft., therefore 6 ft. must be pulled over by the force P, which will, therefore, travel 6 ft. for 1 ft. rise of the load, the weight of which may be six times the pull P. From this we get a very simple rule to find the power of a block and fall. To find the weight that can be lifted by a given pull, multiply the pull by the number of lines of chain between the block and fall; or, to find the pull necessary to lift a given load, divide the load by the number of lines of chain between the block and fall. There are some pulleys called "differential" pulleys of special construction, and should you want to know how to calculate any particular kind, I shall be happy to inform you on receiving particulars. The above applies to all general cases. By combining two or more sets, the power is increased more rapidly: thus, if instead of hanging the load W' direct on the hook K, a similar block and fall were interposed, the power at the hook would be multiplied six times, and the total increase would he thirty-six times P.—F. C.

**Frosted Gold.**—H. H. W. (*Pimlico*).—From a dull surface (produced by polishing with water of ayr stone, and either bluestone or powdered pumice and water, the next step is to either gild or colour the article. Mr. Bonney will tell you about gilding, and I think you will find some information about colouring in "Shop" of No. 19, Vol. I. of WORK, page 301. Once it is gilt or coloured, the thing to do is to scratch-brush it. For that you will require a pretty powerful foot-lathe, some scratch-brushes, and some arrangement to allow a mixture of beer and water to dribble over the brush and the work, while the brush is rapidly revolving. It is this process that is most in use—and it wants a workman who has had experience to get a good surface—and, in fact, this is a special thing, and in our workshop all large surfaces of coloured gold are sent to the gilder to scratch-brush. A scratch-brush on a small polishing lathe will not produce the required surface anyhow. There is another kind of dull-coloured surface sometimes used for Etruscan work, which is nothing but the colour left just as it comes out of the colour-pot. I do not suppose you want that, nor the method followed in Birmingham, which is that of a sand-blast made to impinge on the work. The results by this method are very good, and certainly give an 18-carat appearance to a 9-carat article—for a time. This answer does not do more than indicate the methods, I am aware, but for further information the Editor will have to capture a practical gilder. I, a goldsmith, have not found it worth following up, and writing as my experience dictates, my reply is: "Don't try it yourself" unless you are going in wholesale for gold work.—H. S. G.

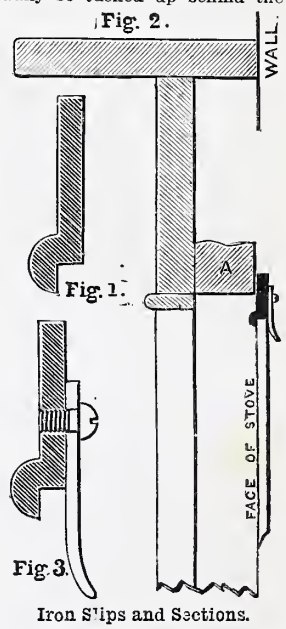
**Galvanising Staples, etc.**—HOLLY READER.—To do galvanising in a small way such as you inquire about, you will want an iron pot or vessel to contain the molten zinc—say about 10 lbs. or 12 lbs. The articles to be galvanised should be, directly after forging, placed in a hot pickle of *killed* spirits; if you can boil them a few minutes it will be all the better. Anything that you can wire together and do several at a time, do so. Use plenty of sal-ammoniac on the zinc. Take the articles out of the pickle, and gently place them in the molten zinc; do not rinse the articles in water before putting in the zinc, or it will sputter all about; but the spirits will not have that effect. Keep the articles in motion till they are thoroughly hot and well covered; then take them out and shake them, and throw them into sawdust. For very small things you might make a kind of wire ladle to hold them whilst in the bath. You can tin wrought-iron goods in the same manner. With regard to enamelling iron, it is beyond an amateurs' skill, as it requires special knowledge and training, only to be got by actual experience.—R. A.

**Phonograph.**—C. T. B. (*Derby*).—An article on the above subject is in the Editor's hands, and will appear when room can be found for it in WORK.

**French Polishing and Mount Cutting.**—C. M. J. (*Perth*).—It would be impossible in the space devoted to "Shop" to answer your query fully as regards French polishing. Ere this appears in print, you will have noticed, if you read the paper carefully, that the subject is already being taken up in a series of articles, the first of which appeared in No. 105, March 21st, and in No. 108, April 11th, to be followed by others, which will give particulars such as will, if followed closely, enable you to obtain a polish such as you have seen on sewing-machine tops as French polished; though, strictly speaking, many of them are not French polished as we use the term, but are polished on a foundation of oil-varnish: a process that requires a large number to work on to make it worth one's while to adopt. Dull polishing is obtained by dusting over the polished surface with fine emery, and well rubbing with a soft rag or brush in the direction of the grain. Sometimes a little linseed oil is used with the emery, and should be done after the final "bodying up," in place of "spiriting out." Mount cutting has been treated on in Vol. II. in "Shop," pages 207, 668, 683; gilding mounts, 207; mount-cutting tool, 669.—LIFEBOAT.

**Designs for Inlaying.**—A. W. (*Hackney Road*).—H. Zilles & Co., 24 to 26, Wilson Street, Finsbury, have some excellent designs for inlaying, but if you want them for furniture they are not altogether in the styles most commonly met with. If you want them for your own use, and not for sale in the ordinary trade channels of your neighbourhood, they are everything that could be desired. Should you prefer to have them in the Italian or prevailing fashionable style, you cannot do better than apply to Mr. Busschotts, Park Lane, Liverpool. He has the largest stock of Italian designs in this country for fret-cutting and inlaying. If you want special designs to your own sizes, you will have to get the patterns drawn out for your own use, or you may be able to get them from some marquetry cutter in your own neighbourhood.—D. A.

**Repairing.**—A. V. H. D. (*Holloway*).—You should not in any case repair defective stoves with wood. You can buy at most of the large ironmongers what are called "Stove Slips." These are slips (of various widths and lengths) of cast iron, supplied for the purpose of making out a stove to a different size to what it is made, and so adapt it to an existing mantel. With one of these slips I think you will be able to get over your difficulty. Fig. 1 is a section of a slip which will suit your purpose, and if you cut it so that it will just go between pilasters, you will find it can readily be tucked up behind the smoke joint, A, Fig. 2, until it gets into position shown, and the only thing that remains to be done is to keep it there. This can be done by screwing two thin iron clips on the back of slip, as Fig. 3; by turning these clips round so that they are parallel with slip until it is tucked into its place, you can pass your arm through the register hole of stove and reach these clips, and pull them into the position shown in Fig. 3, and this will effectually hold the slip in its place. A little plaster of Paris smeared with the hand over the back of slip when it is in its place will help to improve matters. If you find you cannot reach the clips with your hand, drill a small hole in end of clips, and tie a piece of string on end of each, so that by guiding the strings through first, the clips can be pulled down in this way. I should advise you to make a pattern in wood first, and try it that way, and then, in the event of your not being able to buy exactly what you want, it would do to cast from. Your next question as to who the parting garden wall belongs to, and who is responsible for its repair, is a question that very often crops up, and unless it has been specified in the lease, can only be settled by law, there being no clause in the Building Act to cover this particular case. I think you will find the matter generally stands in this way—viz., that if you want to repair, and your next-door neighhour is indifferent if it is repaired or not, you must pay, and *vice versâ*. This is one of those cases where a little give and take is very desirable.—E. D.



Iron Slips and Sections.

**Knotting, Splicing, and Working Cordage.**—H. W.—I would willingly tell you in what numbers of WORK the successive articles on this subject will appear if I could, but it is not possible for me to settle anything of this kind in advance.

**How to Make a Garden Barrow.**—L. P. B. (*Kew Gardens*).—Full instructions on the above, both as to size, construction, etc., will be found in No. 68 of WORK.

**Bleaching Silver.**—W. H. (*Reading*).—W. H. will find this matter dealt with on p. 60, No. 108, Vol. III. of WORK.—H. S. G.

**Emigration.**—PRÆTORIA.—Apply to John Pulker, Esq., Emigrant's Information Office, 31, Broadway, London, S. W.

**Fret Machine.**—J. B. (*Derbyshire*).—I have given other correspondents in "Shop" the information you seek. Refer to back numbers.

**Jewel Case Catches.**—H. A. (*Forest Hill, S.E.*).—These can be obtained of Mr. Child, Meredith Street, Clerkenwell. If the particular sort are not in stock, then get Mr. Bibb, West Street, St. Martin's Lane, to give a quotation to make them. A suitable piece of leather can probably be obtained at Deed & Sons, 91, Oxford Street, or at F. Cooper's, 107, High Holborn, London.—H. S. G.

**Magnetic and Electric Belts.**—J. O. (*Hednesford*).—The electric belts described on page 827, Vol. II. of WORK, in reply to G. F. R. (*Woolwich*), cannot be compared with the belts advertised at 5s. 6d. each, as these may be magnetic belts, made up of permanent magnets sewn on to the belts, and these do not give *electric* currents.—G. E. B.

**Electric Belt.**—W. H. C. (*Homerton*).—G. F. R. (*Woolwich*) inquired for an *electric belt*—that is, a belt to generate a current of electricity. I described such a belt on page 827, Vol. II. of WORK. This belt will generate a current of electricity if moistened with sour sweat or with dilute vinegar. In that description you will read—line 16 onward—"solder a length of wire braid to a copper disc of one pair, then pass it (that is, the length of wire braid) through the belt, and solder the other end to the zinc plate of the *next* pair, and so on." You will thus see that you will need as many lengths of wire as there are plates in the belt. The plates of a pair are opposite each other. The belt you have is, probably, a *magnetic belt*. These appliances only do good when *adapted* to a person's needs. I am investigating such appliances just now to discover their value as remedial and curative agents.—G. E. B.

**Marine Boiler.**—R. A. F. (*Shepherd's Bush*).—You do not state for what description or size of engine the boiler is required. From the size of boat, I judge you may put in a boiler of vertical type, 5 in. in diameter, and about 10 in. high. The fire-box inside may be 4 in. diameter and 3 in. high. From the top of the fire-box you may carry up a number of ¼ in. diameter tubes through the water space to a space whence the chimney springs, or you can carry up a 2 in. diameter vertical flue, and place a number of cross water tubes in it, crossing each other in all directions to present surface to the hot gases of combustion. These tubes may be ½ in. to ⅝ in. in diameter, and should be slightly inclined from the horizontal, to facilitate the circulation of water through them. Another form of boiler which presents advantages in heating surface consists of one or two coiled pipes to contain the water, and upon the surfaces of which the hot gases strike. These coils should communicate at top and bottom with water chambers, preferably of cylindrical form. Copper is the proper material to use, and it must be used for the pipes, but if the expense is in question, the shell and fire-box may be made of sheet-iron. The joints should be strongly brazed together, and the boiler tested with water pressure before you put it under steam. I do not think you will find a charcoal fire successful, and advise you to use a lamp or paraffin burner instead. Unless you have a blast, the charcoal will burn too slowly to make steam, and if you do have a blast you will find great difficulty in keeping your fire stoked. Your boiler should carry a steam dome, safety-valve, and water-gauge.—F. C.

**Making Catgut.**—WORKONIAN.—I am not acquainted with any book devoted to this industry. It is a very dirty one, but those who follow it in my district admit that it pays fairly well, and takes very little capital. The materials—the sheep's "ropes"—are bought from the butcher, and cleaned by turning inside out and well washing with *cold* water. All fatty matter is scraped off. A set runs to from twenty to thirty yards. The gut is twisted whilst "green," and just as we see twine twisted at a rope-walk, one end being fixed, and the other attached to a bobbin set in motion by a larger wheel. A size made from parchment scraps, etc., is afterwards rubbed over the gut, and it is dressed down with a cloth; this gives a finish, as well as serving to keep the twist in place. The smaller intestines serve for making the thinner strings. My neighbours sometimes make gut up to ½ in.; this is done by twisting several strands of intestine together. Bleaching is considered to weaken the gut.—S. W.

**Electro-Plating Outfits.**—E. C (*Wells-by Sea*).—The Gassner dry battery, and any dry material required for electro-plating and electro-gilding, can be supplied you by my brother, who advertises in WORK under the style of Bonney & Co., 19, Avenue Road, Lowisham, S.E. He undertakes to supply jewellers and amateurs with small electro-plating outfits.—G. E. B.

**Induction Coils.**—J. L. (*Canning Town*).—A series of articles on induction coils are in course of preparation. When these appear you will learn how to wind the secondary wire of your coil. A coil to give 1 in. spark should have 1 lb. of No. 36 silk-covered wire as a secondary coil. The primary should be two layers of No. 18 silk-covered wire. All other parts of your coil are right. See that the secondary wire is well insulated. To guard against possible faulty places, run the wire through melted paraffin wax before winding it on the primary, and baste each layer with the wax. You may wind on the secondary in three divisions, but the wire must be continuous throughout, and wound on in one direction only. The coil will be improved by a condenser of fifty sheets of tin-foil placed underneath the base.—G. E. B.

**Electric Bells.**—G. P. (*Edinburgh*).—You will find full instructions on making electric bells in WORK, Vol. I. A series of articles on "Burglar Alarms," including details of electric bell construction, appeared in Nos. 12, 18, 20, 27, 31, and 33. All back numbers are in print. You may also pick up several ideas from previous answers to correspondents in "Shop." Read these first, then if you do not clearly understand any part, or wish for further advice, write again, and I shall be pleased to help you. You will find an idea for an electric time alarum in No. 32, and several illustrated ideas in Vol. II., on pages 157, 175, 226, 416, 582, 699, and 723.—G. E. B.

**Fixing Chalk Drawings by Sprinkling.**—R. O. (*Handsworth*) can do this with isinglass dissolved in water, taking up his size with a camel-hair brush, and getting his "spurts" by using a comb. An old way of fixing chalk is with *warm* isinglass size, applied at the back of the paper.—S. W.

## IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**Soldering Delicate Gold Articles.**—H. S. G. (*Battersea*) writes, in reply to NORTHERNER (see page 734, Vol. II.):—"NORTHERNER asks for a few hints on this matter, as he has failed in an attempt to solder the thin bezel of a watch and has melted it. The cause of his failure may have been that the solder was of too good a quality, although that is but a poor excuse, for a workman should watch all his work for indications of overheating all the time that he is trying to solder one part. If the solder is not in fault, as it well may be if the bezel was from a Geneva watch, then there was probably dirt or grease about somewhere, either on the bezel, on the solder, or mixed with the borax. In fact, any impurity will hinder soldering; therefore one must always take care to have everything clean and free from dust or grease, and be very particular to scrape the solder bright, as well as the edges of the work where the solder is to run. I think I should have annealed and boiled out the bezel before scraping and applying the borax, then I should have given myself a fair chance to succeed. As to soldering delicate articles generally, to be successful in that class of work is not given to everybody. Success depends (after proper preparation of the work, cleanliness, etc.) on the ability to control and direct the flame of the blowpipe. Flames to solder with are roughly divisible into two—pointed and spread: the latter is what is wanted here. It is produced by holding the point of the blowpipe a short distance away from the flame—say, ¼ in. to ½ in.—and then blowing with a very gentle and regular blast so as to envelop with a quiet flame a large portion of the article until the solder runs or the work begins to show signs of sweating, when, of course, no more heat should be given. If the foregoing is not minute enough in its details, then write again."

**Dry Battery.**—F. A. (*Portsmouth*) writes, in reply to ELECTRIC (see page 14, Vol. III.):—"I think the following will be of use to you for a dry battery: Oxide of zinc, ¼ lb.; plaster of Paris, 2 lbs.; chloride of zinc, 1 lb.; water, 3 pints; zinc and carbon to be used as elements."

**Enlarging Drawing.**—A. N. F. C. writes, in answer to J. W. (*Edinburgh*) (see page 14, Vol. III.): "To enlarge, multiply, to diminish, divide, each side by the square root of 2 (=1·4142...., the nearest fraction to which in common use is 1⅖)."

**Wood-Slicing Machine.**—DEXTER HANDY writes, in reply to W. H. (*Belfast*), who asks (see page 782, Vol. II.) where he can procure a machine for slicing wood as thin and clean as that used for bandbox making:—"La Maison Arbey, Cours de Vincennes, Paris, make such machines, and if W. H. does not hear of a maker nearer home, he may like to apply to the above-named firm. They make a fine machine which will slice wood up to ·005 metre thick by 1 metre long and ·35 metre wide—in our measurements, say ⅛ in. thick by 39 in. long by 13¾ in. wide."

**Draught Board.**—T. C. R. (*Liverpool*) writes, in answer to J. W. M. (*Driffield*) (see page 782, Vol. II.): "Take a sheet of paper size of glass, mark width of border from each edge, and allow ¼ in. for rabbet of frame. Tick off upon inside lines number of squares, and connect points. This will give plan of board, and when placed underneath glass correct guidance for painting. For simplicity and good effect take lamp-black in oil, thin with varnish and turpentine, and by the aid of straight-edge and lining-pitch run all lines upon glass as seen through it. For width, say, squares 1 1/16 in., border ⅞ in., and ⅜ in. band running through centre for relief or other work, as fancy dictates. When this is dry, proceed to lay in alternate squares white and green of medium depth; the border a brown leather, cigar, or fawn colour: care being taken to make colour cover solid, or it will want re-coating, as in the case of the white, and a coat of this pigment spread over the whole will give additional solidity, and act as a preservative. For frame, procure plain moulding. Stain this walnut and varnish, or German mould from picture-shop, which is very cheap, but not so durable or consistent with use, in this case being faced with composition, and liable to chip, showing the white underneath. Four shillings should cover cost of above, presuming painting done by oneself, and tools to hand. There would be no difficulty in fitting boards to legs; and any handy joiner would give estimate for so simple a construction."

## V.—BRIEF ACKNOWLEDGMENTS.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—W. M. F. (*Elginshire*); C. R. (*Paris*); C. W. T. (*Manchester*); APPRENTICE; CARVER; PERPLEXED; C. G. M. S. (*Dezon*); A. E. S. (*Glasgow*); CONSTANT READER; B. O. (*Stoke-on-Trent*); CUTLER; T. R. (*Middlesbro'*); P. P. (*Manchester*); J. B. W. FOR ALL WORKMEN, PROFESSIONAL AND AMATEUR.

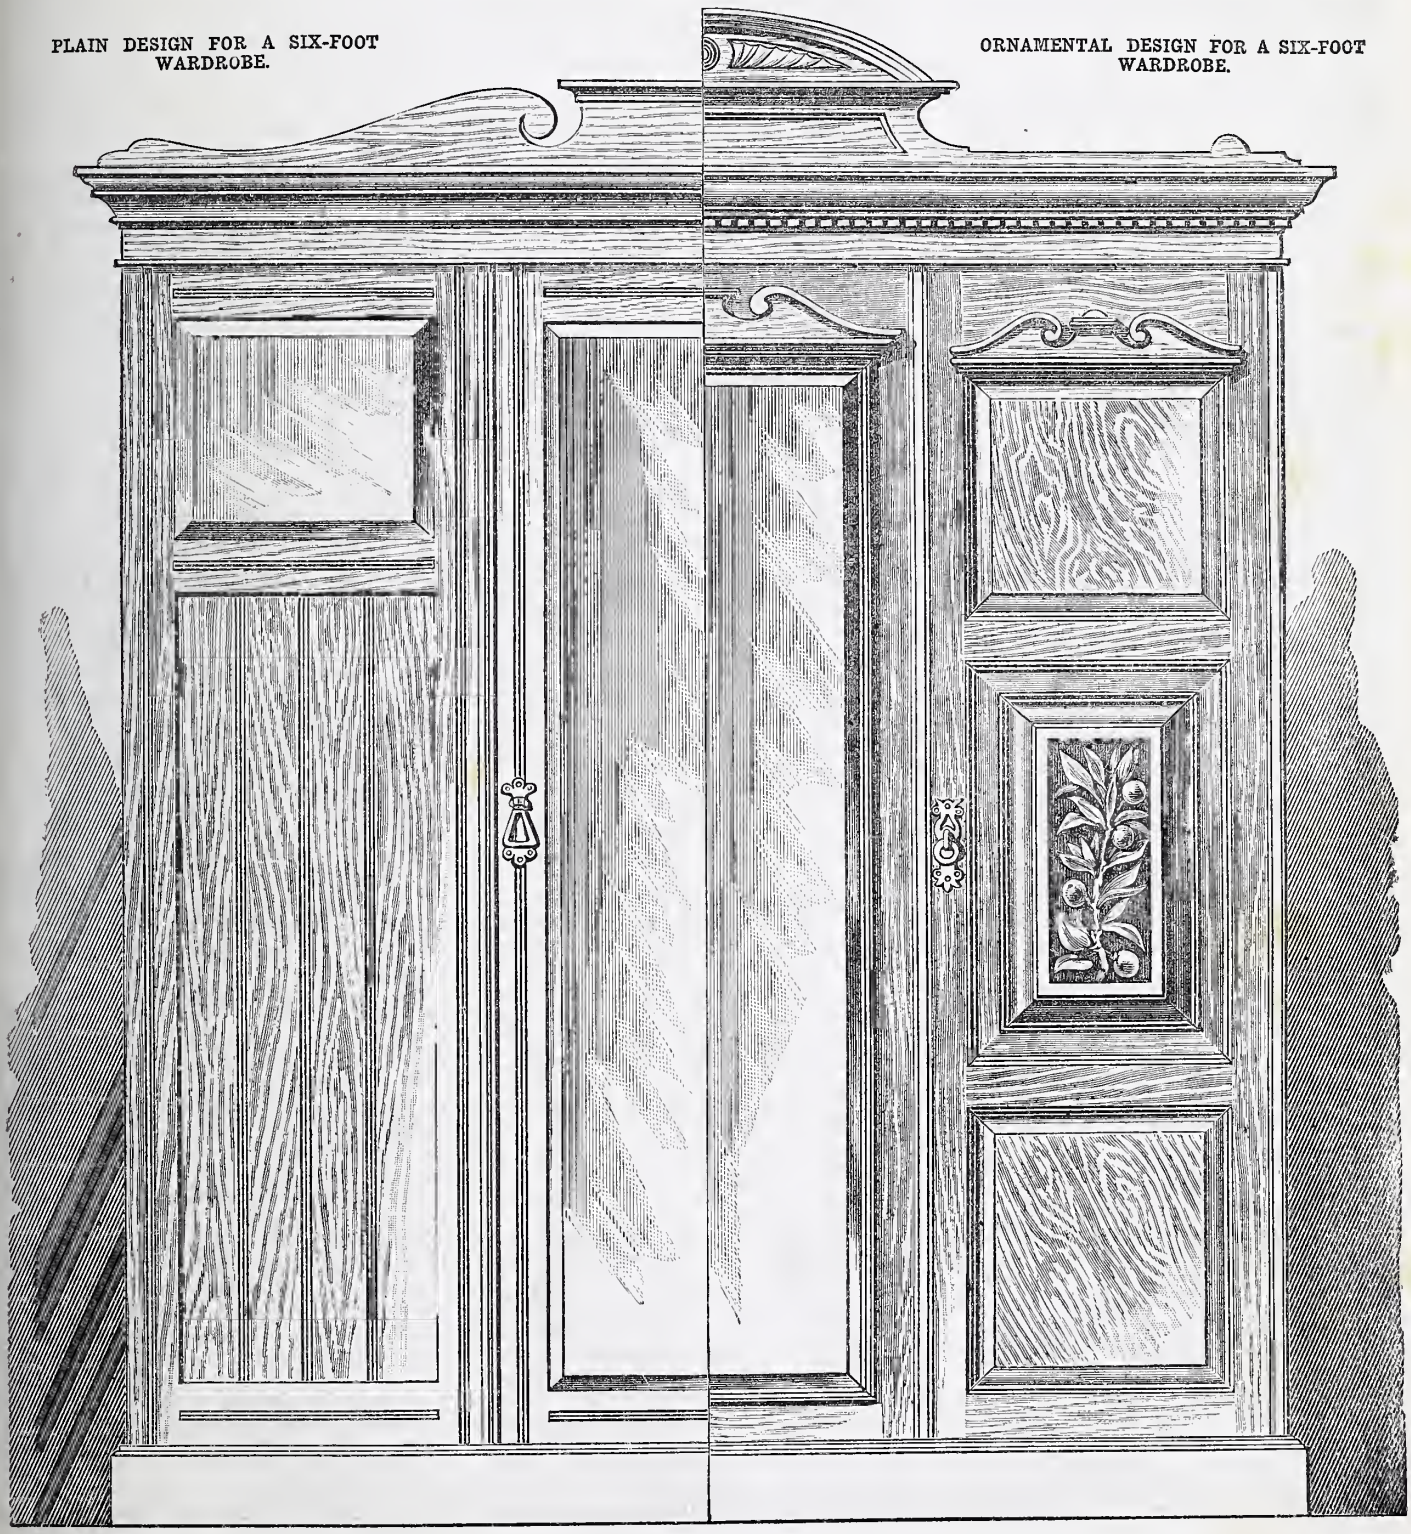
[*All Rights reserved.*]

VOL. III.—No. 116.] SATURDAY, JUNE 6, 1891. [PRICE ONE PENNY.

PLAIN DESIGN FOR A SIX-FOOT WARDROBE.

ORNAMENTAL DESIGN FOR A SIX-FOOT WARDROBE.



## HOW TO MAKE A SIX-FOOT WARDROBE.

BY AN OLD HAND.

Introductory—Size—Size of Ends—Parts Forming Wardrobe, Drawers, Trays—Hanging Part—Bonnet Box and Drawer—Hooks—Shelf—Lining—Plinth—Cornice—Doors—Short Trays and Drawers.

The construction of a large wardrobe is a job not to be undertaken by the novice; therefore the following suggestions are offered more for the consideration of the expert workman, who, while thoroughly proficient in the manipulative part of joinery, is not altogether at home in making up articles of furniture, than for those who do not understand the use of tools and the necessary joints. The amateur and the beginner are warned that the following remarks will require reading between the lines if they are to be of any benefit, for I do not so much wish to write detailed directions as to endeavour to represent what may be regarded more in the light of a friendly workshop chat over the bench between two experts in joinery, one of whom may never have had his attention directed to wardrobes. But perhaps one of the good old school of artisan—or shall I not rather call him a tool-using labourer?—who objects to the new-fashioned notions of letting people know so much in "these 'cre papers" may repudiate the notion that a quill-driving creature can tell the practical man anything worth knowing. We all of us know such types of individual, unpleasant to work with, and not, as a rule, quite so clever as he assumes to be. Well, I do not address my observations to him, and only make them in the hope that they may be useful to some of those younger members of my trade—that of a cabinet-maker—who do not object to learn. Everyone of them will know that to say everything that might be told about a 6 ft. wardrobe would take a long time, and I can barely touch the general outlines. For instance, I shall assume that the reader knows how to set out work, make doors and drawers, and the manipulation of the tools required, so that nothing need be said about such details.

Although the size of the wardrobe has been stated in the heading of this article to be 6 ft., there is no reason why a similar article of furniture should not be made either much smaller, or, on the contrary, much larger. The width stated is, however, a good standard or average one, and when a "three-door, long-tray wardrobe" is mentioned, the size that most of those in the furniture trade will conclude it to be is that named. As limits for wardrobes of this construction, 5 ft. and 8 ft. for the smaller and larger may be given; but probably more of them are made 6 ft. wide or thereabouts than of all the other possible measurements put together.

The height of such a wardrobe, whatever the internal fittings may be, will to some extent depend on circumstances, and the following considerations may be some guide to the maker:—That of cost must not be omitted, for, unfortunately for the turning out of really good articles of furniture, it is of prime importance, and "cheeseparing" must be practised sometimes both in work and material if a job is to pay. Now, a wardrobe is a big thing and swallows up some stuff, so that it may be necessary to reduce the quantity as much as possible, not only by keeping the height down, but also the depth from back to front. Why, by this means 4 ft. of stuff can be saved in the ends alone by having them 6 ft. 6 in. by 1 ft. 6 in. instead of 7 ft. by 2 ft. As there are four ends—two inner and two outer—and it may fairly be assumed that these latter are solid, here is a possible saving at once. True, rather extreme measurements have been taken for the ends, but neither of them would be regarded as unsuitable. Increased height adds importance to the work, but it should be remembered that, if it is excessive, convenience may be sacrificed to appearance, for the most convenient wardrobe is undoubtedly that in which most of the contents can be got at without mounting on a chair or steps.

For a 6 ft. wardrobe, a good ordinary size for the ends may be stated as about 6 ft. by 1 ft. 8 in. With a cornice 6 in. deep, or a little more, and a 5 in. plinth, we thus get the total height over all, exclusive of pediment, of about 7 ft. A reduction of 6 in. would make the wardrobe a low one, while, to use the language of our friends of the hammer and rostrum, an addition to the same extent would make the article "noble and massive." The size having been determined on, something will have to be said about the construction, which is by no means difficult to those who can handle their materials. Now, as I have suggested, this—or, indeed, any other form of three-door wardrobe—may be fitted up in what is probably the most popular form of arrangement among buyers, viz., that with sliding trays and drawers extending across two-thirds of the width, and the remaining third being a hanging cupboard.

So far as cabinet work is concerned, there might be no difficulty in making the wardrobe in one piece, but as it would then be inconveniently large and very difficult to remove or get into many ordinary rooms, it is generally—I may say invariably—made in parts. The three-door wardrobe with long trays and drawers is therefore nothing but a collection of parts fitted to, and to a certain extent independent of, each other. For all practical purposes it may be considered that such a piece of furniture consists of five parts—viz., the three principal portions of the carcase, the plinth, and the cornice. Of course, in addition to these are doors, drawers, and trays.

Two-thirds of the wardrobe being occupied with the latter, were one case made to hold them both, the size would be inconveniently great. This two-thirds, or, to put it in other words, the part which is enclosed by two of the doors, is therefore made in two portions, the lower one containing drawers and the upper the sliding trays. The former is nothing but a perfectly plain chest of drawers, while the latter is even simpler, as the trays simply slide either on slips fastened on to the ends of the case, or, better, by means of slips fastened on the ends of the trays and fitting into corresponding grooves in the case. May I here suggest, for the benefit of any "Curtain Road" furniture maker—or rather, dealer—who may see these lines, that good cabinet-makers in "the country" do not altogether appreciate the extremely shallow trays which London trade makers put in. I have known more than once these to be taken out and replaced by good deep trays such as are generally supplied in Scotch wardrobes. Yes, I know all about the reasons for shallow trays—price and all that sort of thing—and that the makers would not get any extra consideration when selling on the "buzz" in or near the Road, but the fact remains that the common London-made wardrobe is in regard to trays not of the best, and I suppose it is within the province of Work to give a few hints even to metropolitan readers. I do sometimes think that we in the country—by which I mean the cockney's definition—can often give them hints as well as receive them.

The parts containing the drawers and trays must fit together accurately, and are secured to each other when the wardrobe is made up by screws. Only one end need be solid, for the other, as well as the two tops, are not seen, and may be (as they generally are) of pine.

The hanging part is merely a plain cupboard behind the third door, and may be of pine except the outer end. The inner end of it and of the other two portions are, when fitting up, screwed together.

The fittings inside the hanging cupboard vary, but are usually of a very simple character, and it will be sufficient just to indicate arrangements that are often adopted.

Where ladies are concerned—and they generally are in connection with wardrobes—the bonnet box or drawer is usually considered indispensable. The bonnet box which will no doubt occur to most readers as being commonly seen is the familiar and not indestructible bandbox; but, as behoves the cabinet-maker, he must make something more substantial—in fact, he must make something to contain bandboxes. For this purpose the "bonnet box" or drawer of a wardrobe is usually made sufficiently deep to hold several of the others; and, indeed, I do not remember of any lady having ever complained of one being too deep. If it is made to hold two layers of bandboxes, there will not be any complaint on that score; but if made much deeper, the hanging space might be inconveniently diminished thereby.

When a plain drawer is made, there will be no difficulty in its construction, but on several accounts a drawer is not so convenient as a box. This is hardly more than a trade term, for in a strict sense the receptacle is not a box. In one form—and that perhaps the simplest as well as the most convenient—the top is a fixture or shelf enclosed below, with a fall-down front or door hinged at the bottom, and secured at the top with a spring catch.

A very similar construction is that in which the front is fastened and the shelf or lid is hinged near the back. In this case, things which may be on the shelf have to be removed before access can be gained to the interior of the box.

Another form of construction, and one entailing more work, is to make the top in the form of a sliding tray, which must be drawn out to get at the inside of the box.

It is entirely a matter of fancy on the user's part which is the best form to adopt, and, so far as the maker is concerned, a question of cost and which he thinks will suit his customers best.

Leaving the lower portion of the cupboard, let us turn to the top. Hooks here are regarded as indispensable. They are usually fixed in a row on the back and both ends,—or, as we should say, "all round"—and are fastened first on to rails, which are then secured in their places. As the back is seldom thick enough to hold the hooks, a rail must be used there; and it is better, though not so necessary, to have them on the ends. When a really first-class job is wanted, the rails on which the hooks are fastened are made to slide in and out. Above the hooks a shelf is often placed; but as the space for hanging might then be

made too short, it is generally found only when there is no bonnet box below.

It may be useful to mention that the hanging compartment is seldom supposed to be finished till it has been lined—a glazed, striped lining being generally used for this purpose. Though it is more the work of the upholsterer—generally only a young one—than of the cabinet-maker, the "jobbing hand" may be glad to know that the lining can be stuck on with strong paste applied to the wood, from which any ochre colouring—and there generally is some to disguise the pine in wardrobes bought in the neighbourhood already indicated—should be thoroughly washed off first. Lining is not a difficult job.

The plinth and cornice have been sufficiently mentioned, but it may be well to say that the latter should be fairly heavy in appearance, as shown in the illustration, which is drawn approximately to 1 in. scale, and should not consist merely of a slight moulding. To facilitate fitting together of the various parts, blocks should be fastened on to the top and bottom of the carcases, and fitting into the corners of the plinth and cornice.

The doors may be hinged within the ends or on them, the method, of course, being determined beforehand. When hinged within, the end must be thickened up for the trays to pass. The centre door—of which, by the way, the panel is generally looking-glass—may be either hung with centre hinges let into top and bottom, or with ordinary butts. In this case both ends of the hanging compartment project to an equal extent, and the hinges are fastened to the inner one, the edge of which should be faced up to match the rest of the outside.

To discuss the whole matter of hingeing wardrobe doors would, however, require considerable space, and no doubt enough has been said to enable any practical man to do what is necessary. If not, perhaps he will kindly state his difficulty for answer in the "Shop" column.

With the remark that a wardrobe of exactly the same external appearance may be made with short trays and drawers in one or other—usually the centre—of three carcases, these few hints on a 6 ft. long-tray wardrobe must be brought to a close, leaving the intelligent worker to make such modifications as may seem desirable to him.

## TO CLEAN WALL PAPERS.

BY E. W.

Stale Bread *v.* Dough—The Dough: How Made and How Used—Useful for Ceilings—An Example.

The value of stale bread for the purpose of cleaning wall papers is very generally known, and its service more largely requisitioned than that of all other substances. It is splendid for the job, and deservedly in favour, but in many respects is not equal to the comparatively unknown "dough" process. This latter is cheaper, quicker, leaves no dust or crumbs about, and, with moderate care, will make an equally good job with a far less expenditure of labour. The dough for this purpose is simply a mixture of coarse flour and water, the coarser the flour the better, of rather stiffer consistency than for a pudding. About 1 lb. or 1½ lbs. of flour will be sufficient to clean the walls of, at least, one good-sized room, even though the paper be very dirty. The loose dust on the walls should first be removed by a soft broom or brush, and then the lump of dough passed lightly over the paper, when it will be seen to remove the dirt in its path as effectively as an indiarubber squeegee removes liquid mud from an asphalte road. The dough in use works soft, and in consequence it will be found desirable to have some flour in a bowl to roll it in occasionally. If not intended to wash the ceiling, it may with advantage be treated the same as the walls, though, if thus done, it will not, of course, have the brilliant whiteness of a fresh-washed ceiling. By this means I have, in less than an hour, well cleaned the walls and ceiling of a room 14 ft. by 12 ft. by 8 ft. The walls and ceiling were very smoky and dirty when I began, and the walls showed in very pronounced patches the parts that had been covered by pictures, pier-glass, furniture, etc., but when finished they presented an evenly clean appearance suggestive of new paper; the ceiling also looked very clean and presentable, though previously blackened by smoke. Certainly, for simplicity, ease, cheapness, and the facility with which this work can be done by anyone without any previous experience of such, this method of cleaning must commend itself to all who are actively desirous of securing a clean, attractive, and healthy home.

## APPLIANCES FOR WORK TO BE MADE BY THE WORKER.

BY B. A. BAXTER.

Guide for Dado Groove, used for Grooving for Partitions—Trough for Planing Blind-Lath Edges—For Piano Small Work—Zinc Templates for Mortises, Contour of Mouldings, etc.—Suggestive Value of Articles on Beehives in "Work"—Mitre Templates of Various Kinds—Mortises to Pattern—Boring Collars—Setting out for Dowelling—Advice to Watch a Polisher or Carver—Fixing Small Hinges.

For grooving across a board with a dado plane, the benefit derived from the use of a guide is not to be despised; the guide may be a piece of ½ in. wood having a straight edge, and it may usually be fixed with a bench holdfast, which, though it cannot be made by the wood-worker, is one of the most useful additions to his bench that he can possess (Fig. 25).

In cases where grooves are to be made at regular intervals, a piece of wood, having affixed to the underside of it a piece that fits the groove last made, will be useful; all that is needful is to be sure that the strip fitting into the groove is parallel with the edge which guides the plane, and that it fits the groove accurately (Fig. 26).

The "trough," used to reduce blind laths, etc., to a uniform width, ought to be mentioned as suggestive, though blind laths are cut so accurately now that the trough is not required for that purpose (Figs. 27, 28).

Very much akin to this is a contrivance used by pianoforte makers to plane hammer-heads, etc., to the exact thickness. As some readers are aware, the small parts of pianos are made by shaping lengths of wood cut across the grain to the desired figure, and then cutting slice after slice off by means of a circular saw. This plan to plane the parts to accurate thickness merely consists in fixing on a piece of wood two strips of the proper thickness so that the edges of the trying plane move upon them, while the articles to be planed are placed between and therefore in the path of the cutter (Fig. 29).

It may not be too obvious to mention the great utility of zinc templates cut to the figure of a rebate or a moulding, cheap and useful, and easily cut with strong scissors, saws, or chisels and gouges.

Various grooved or rebated pieces of wood which are useful to hold long, thin strips while being planed or rounded merely mentioned will suffice, although appliances suitable for all purposes will never be fully described; reference here to the papers on beehives and appliances will show what I mean: it is not necessary (perhaps not allowable for me) to speak of the merits of those papers, especially *this* feature of them.

Appliances rendering chisels more accurate in action and results strictly might include planes, by a stretch of licence, for a plane *is* merely a chisel so fixed in a block of wood that its angle is constant and its penetration limited; but for chisels merely, help is required to enable the worker to make the best use of them. The template for mitres is perhaps the most useful and best known (Fig. 30).

A diagram is here given of a template for cutting applied mouldings to ornament a panel; this template will serve for both sawing and finishing with chisel, and is made so that the moulding just fills the groove in the template (Fig. 31).

A template for stop-chamfer work is useful and easily made; the intersection of the angle of 45° on each face of the wood gives a facet equilateral and therefore equiangular, if the template and the material are accurate.

For making mortises, etc., for forms, door-frames, and anything beyond the usual scope of a mortise-gauge, it is useful to make model mortises on a piece of wood that can be applied to the work, and there is this advantage, that the same strip will do for the marking of the tenons as well (Fig. 32).

I remember well being led to this by being engaged with another in making forms, and my comrade would not or could not see the advantage of making all the similar parts interchangeable, so as he made the mortises, I had to make every standard a separate fitting.

For boring, we can help ourselves in obtaining uniformity of results by easily contrived expedients.

First as to the depth, we can of course bore a hole with the bit itself, and the piece of wood forming the depth gauge only needs to remain on the boring tool and to extend from the collar of the brace to the wood being worked on; in the case of centre-bits or other boring tools larger than the shoulder of the brace, two pieces of hard wood can be notched to fit the stem of bit and screwed together on it at the position desired (Fig. 33). Here, however, I feel compelled to make a digression, to tell of a countersink which also acts as a depth-gauge, useful to all who bore for screws; it is of steel with a hole in the centre and a cutter wound round the hole in a spiral form; it has a screw to adjust and fix it on to any pin, spoon, or nose-bit, not exceeding the size of the hole in centre. I am told that it will work satisfactorily with any bit, though considerably smaller than the hole in centre; this is because the adjusting screw brings the cutting edge into prominence. It is to be had at all first-rate tool warehouses, or will be soon, on account of its utility. I saw it at Melhuish's.

But to return to our home-made appliances: the need of some help to accuracy in dowelled work is so great that most workers

who make anything in which dowels play any important part are glad to have assistance. Let us suppose that a joint is dowelled with three dowels, we know that the thoughtful worker will not put them in line, or too close together.

Let us imagine a thin veneer or a card or piece of sheet metal is interposed between the pieces of wood to be joined, three pin-holes bored in the thin wood or metal can easily be transferred to either face of the joint, and so the distance apart of the three dowels may be equal each to each in both pieces to be joined; but if there is also a stop or a guard to one edge of the gauge, not only will the distance apart be correct, but the distance from the edge will be ascertained, and if the end needs to be flush, then a stop on the end will materially help accurate boring (Fig. 34).

There are many other expedients which may be adopted with advantage, but they are too numerous to mention here.

It is often instructive to see how a carver or a French polisher will make rough but efficient arrangements for the holding of his work, but I may mention a trifle which I have found very useful: it is merely a turned pin having a square-shouldered head, $\frac{7}{8}$ in. in the stem, and about 3 in. long, the head about $1\frac{1}{2}$ in. in diameter, and about $1\frac{7}{8}$ in. long; the $\frac{7}{8}$ in. portion is tapped, and the holes in the side of the bench are also tapped to fit. One or two holes on the top of the bench are also bored and tapped, and this little arrangement alone (or with the aid of a piece of wood in which the turned pin moves freely—that is, with a hole just large enough to clear the screwed portion) forms a simple and most useful help in cutting shoulders, sticking mouldings, and other similar works; used in the sideboard of the bench it not only supports the board, but also holds it to the bench. If thought desirable, the piece of wood just mentioned can be made 12 in. long, and a thrust screw fitted to one end: it then becomes in effect a hand-screw, and the bench one of the jaws; but I have found the simpler form sufficient for so many varied wants that the last-mentioned arrangement has been discarded. This is shown in Fig. 36, but the piese of wood is omitted, the head of the screw is shown round like a mushroom-headed screw, and the side of the bench is shown in a flat or horizontal position instead of a vertical position.

For fixing small hinges uniformly on a number of small boxes, a piece of zinc folded to a right angle having holes just where the screws for the hinges ought to be put has been very useful, enabling a lad to place hinges with little trouble to himself if greater trouble had been required, he would not have supplied it (Fig. 35).

All these are mentioned as being suggestive, and if anything here mentioned proves to be useful, the writer will have his reward but if this paper should lead anyone to try and devise some special aid to help accuracy and uniformity, then he will have had the greater satisfaction of helping the reader to help himself in a very true and real manner. It is, in short, in indicating to the wood-worker how he may facilitate his work by the adoption of some small contrivance that the value of this paper lies.

In point of fact, in carrying out any kind of work, and especially work in wood, it is surprising how the worker may help himself by resorting to some dodge or other similar to those which have been described above and in the preceding paper on this subject, and in this opinion I am inclined to think no practical man will be found who will refuse to concur, when he looks back over the extent of his own experience.

## HOW TO MAKE A THERMOMETER.

BY J. G. LISTER.

KINDS OF GLASS — THEIR ADVANTAGES AND DRAWBACKS — APPARATUS AND MATERIALS REQUIRED—CONSTRUCTION OF TUBE—FLUIDS EMPLOYED—FILLING WITH FLUID—CLOSING—GRADUATION—FREEZING POINT AND BOILING POINT—HOW OBTAINED.

[T will be well perhaps to preface our remarks on the operations necessary to the production of a thermometer with a few general observations on the nature and uses of different kinds of glass tubing.

Tubes are made of three kinds of glass: viz., lead, soda, and potash or hard glass, according to the principal ingredient, besides silica, present. Each has its special advantages, and each its special difficulty of manipulation. Soda-glass is soft and easy to work upon, but is liable to crack during subsequent cooling. Lead-glass is a little more difficult to handle, and in inexperienced hands is likely to be marred by the production of unsightly blotches of reduced metal, but is much less liable to crack during cooling. Potash-glass is very hard, and will resist great heat, hence it is more difficult to manipulate, but is not open to the same objection—cracking—as soda-glass or reduction as in lead-glass.

Now as to details. The apparatus required will be a lamp, preferably a Bunsen, blowpipe, small glass or earthenware basin, saucepan, small file ("three-square"), and a small funnel; and as materials some glass tubing, mercury or methylated spirit, and a few pieces of ice. The tubing should be what is called thermometer tubing, usually sold at 2s. per lb. under the numbers 33, 34, 35, and 36. Of this, ¼ lb. will be ample to make half a dozen thermometers, including failures.

Having all in readiness, we commence by cutting off a length of 14 to 16 in. of tube by means of the file: first making a notch, and then by a sharp pull separating the portion. The end of this short length must now be softened in the blowpipe flame, and continually rotated until the hole closes, and about ⅛ to ⅜ of an inch is thoroughly softened. Then blow into the other end, using the muscles of the cheek only, until a bulb of the required size has been produced. At about 2 in. from the other end of the tube soften a small portion (about ½ in.), and, by means of a steady pull, cause the diameter of the tube to contract to such an extent that there is only the very finest of capillary tubes joining the two portions. This must be done with a firm but gentle hand; and while the tube is still soft, bend it to an acute angle with the greater length of the tube. Now break off the shorter length about the middle of the constriction, and the tube is ready for filling.

The fluids usually employed are coloured alcohol (methylated spirit coloured with any aniline colour; a small piece of copying-pencil serves very well) or mercury, though for most purposes the latter is preferable, for the following reasons:—First, it is opaque, and hence is readily seen; secondly, it does not wet the glass, and there is less error due to surface tension; thirdly, its co-efficient of expansion is large, and its specific heat is very low (·033 : *i.e.*, it requires less than $\frac{1}{30}$th of the heat required by water to make it expand to the same extent); and fourthly, its boiling point is high (662° F.), and its freezing point is low (— 38° F.), thus giving it a very great range of temperature.

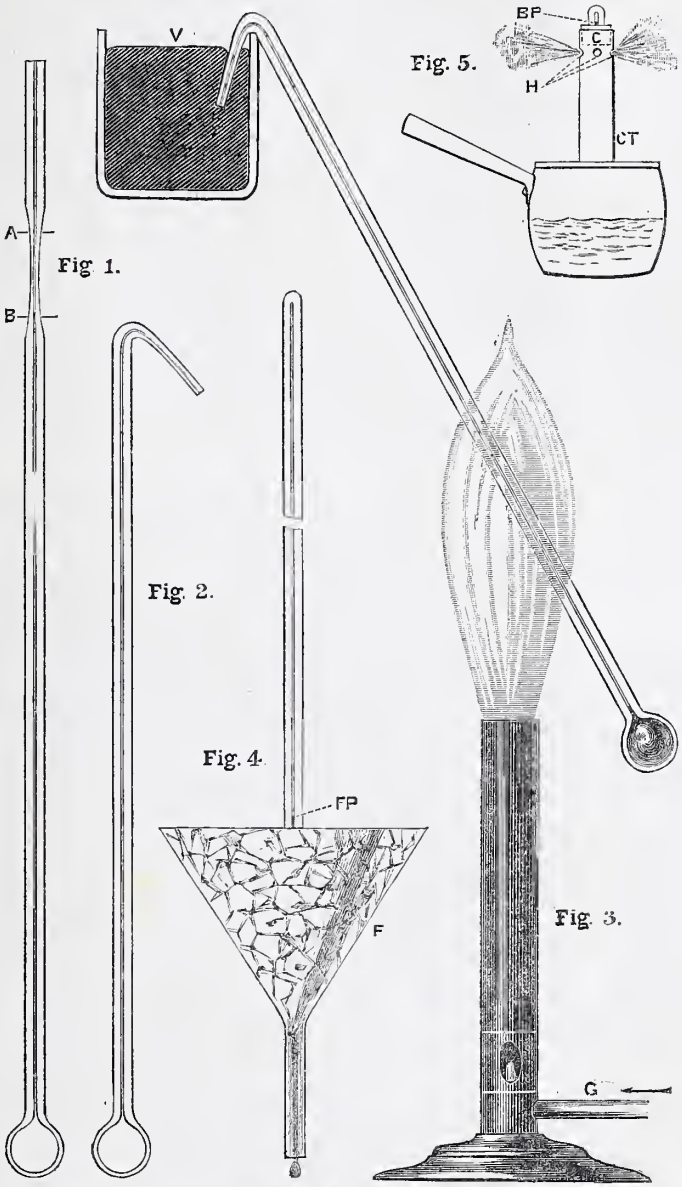

Fig. 1. Fig. 2. Fig. 4. Fig. 3. Fig. 5.

**Fig. 1.—Tube drawn out ready for cutting at A and bending at B. Fig. 2.—Tube bent ready for filling. Fig. 3.—Bunsen Lamp for expelling Air—G, Tube to Gas; V, Vessel holding Mercury. Fig. 4.—Mode of obtaining Freezing Point—F, Funnel containing Melting Ice; F P, Freezing Point. Fig. 5.—Mode of obtaining Boiling Point—C, Cork; C T, Cardboard Tube and Temporary Lid; H, Holes for Escaping Steam; BP, Boiling Point.**

We are now ready to fill our tube with liquid. Place some mercury in the small dish, raise it on a support of some kind, and hang the tube by the bent portion over the edge, so that the open capillary end dips under the surface of the mercury. Now gently heat the tube, to expand and drive out some of the enclosed air. Remove the lamp, and as the small amount of remaining air contracts, some of the mercury will be forced into the tube by atmospheric pressure. This must be repeated until the whole of the tube and bulb are filled with mercury. (If any mercury should stick in the tube, a few gentle taps with the finger-nail will generally cause it to flow downwards.) The final operation consists of removing the tube from the vessel, and heating the bulb *and* tube so as to bring the mercury near, but not quite to, its boiling point. This will cause it to expand, and will further drive out any imprisoned air, so that the tube will contain nothing but mercury and mercury vapour. Now, whilst the tube is still being heated, hermetically seal the capillary end by fusing in the blowpipe flame (taking care to *immediately* remove the lamp from the tube), and our thermometer is made, and it only remains to graduate it. Of course, in the final stage two sources of heat are necessary—one to heat the tube, and the other to use with the blowpipe; for the latter, a No. 12 tallow dip serves excellently.

Now as to graduation. The first thing is to obtain two fixed points: viz., boiling and freezing points (of water). To obtain the latter, which is usually got first, the tube must be inserted in *melting* ice, and a mark made on the glass just at the lowest point to which the mercury recedes. To obtain boiling point, the tube must be placed in the steam from boiling water, and a mark made on the tube at the highest point reached by the mercury. To do this, we must make sure that the *whole* column of mercury is in the steam. This can be done by replacing the lid of the saucepan by a piece of cardboard with a hole in it, in which is inserted a tube about 1½ in. diameter and 10 in. long, with a bored cork in the upper end, and a hole in the side to allow the steam to escape. By this means the whole of the tube and mercury will be kept at the B.P.

We must now decide what kind of thermometer we wish, Celsius (or Centigrade), Réaumur, or Fahrenheit. If Centigrade, then divide the space between B.P. and F.P. into 100 equal divisions, or 50 if great accuracy is not required, and each will be a degree (or two). If Réaumur, then divide into 80 equal parts. If Fahrenheit, divide into 180 equal divisions. Mark freezing point O° in C. and R., and 32° in F. If greater range be required, continue the divisions above B.P. and below F.P., taking care, of course, to put the correct numbers thereto.

The tube is usually let into a piece of wood, and held in the slot cut for its reception by small metal bands, or it may be secured by wire to a metal plate or even to a piece of cardboard, a hole being cut in either material for the reception of the bulb. The graduation should be made on the wood, metal, or cardboard to which the tube is attached, after determining boiling and freezing points on the glass. As this merely requires careful division of the space intercepted between these points into degrees, no instruction on the *modus operandi* is needed.

## SOME WORDS TO WOULD-BE PATENTEES.

BY "AN INVENTOR."

INTRODUCTION — SPECIFICATIONS IN THE LAW COURTS—EMPLOYMENT OF PATENT AGENTS—AMENDMENT OF BAD PATENTS—SEARCHING—HELP AFFORDED BY THE PATENT OFFICE—FIRST THING TO BE DONE — PROVISIONAL SPECIFICATION — COMPLETE SPECIFICATION — PROVISIONAL PROTECTION: ITS MEANING, USE, AND EFFECT—PUBLIC USE OR KNOWLEDGE—UTILITY—FIRST AND TRUE INVENTOR.

HAVING read the papers written and remarks made in Vol. I. of WORK by "C. C. C.," page 545; "Minerva," page 446; "Patentee," page 574; "Loco," page 766; and "A Consulting Engineer," page 694, and being sure that WORK is intended to teach and show people how to do things themselves, I propose—being one who always prefers to do a thing myself if possible rather than to get it done by others—to add and explain in this article certain matters that as yet have not been touched on.

I read the article of "C. C. C." at the date of publication (Nov. 16th, 1889), and came to the conclusion that he was an intelligent amateur who had picked his knowledge up from popular works, and his experience of getting specifications passed through the Patent Office; therefore it is not at all surprising that he should make a mistake or two; but this much must be said in his favour—viz., the information and instructions that he does give are sufficient to draw up a *valid* patent, providing the article, or process, described is new and useful, and that the applicant is the first and true inventor.

It is quite a new doctrine to me that a patent specification should have to go through the Law Courts before being considered a "success." True, such an one stands on a better and different footing, but as "prevention is always better than cure," a specification so drawn that no one dare challenge it in the Law Courts is, in my opinion—and, no doubt, is also in that of everyone else—a more "successful" one than one drawn with *a point to argue on*, on purpose to find work for lawyers, patent agents, etc., to pocket fees, and so harvest some of the fruits resulting if the invention turns out a success. The great drawback to employing patent agents and other professional men in drawing up legal documents is, that while they take reasonable precautions to do the work so that it will stand the test of the Law Courts, they always leave a point or two open to argument. This invites litigation, and while a lawyer will not go into Court if he has no point to argue on, he will readily do so if he has, and the fees are forthcoming.

There is another drawback against employing a patent agent — viz., he always gives the address of his own office as the address of the patentee, if he lives in the United Kingdom of Great Britain and Ireland, no matter in what part. He does this on purpose to intercept any communication intended for the patentee, so that if it means a sale of the patent, or a licence, they can put their fingers on, in the shape of the inevitable "commission." This proceeding is not strictly a legal description of the patentee, and is one I should like to see "sat on." It passes, however, on the ruling "that everything is to be construed in the most beneficial manner for the advantage of the patentee," and the Courts will not annul a patent except for very good and sufficient reasons.

In one of the papers to which reference is made above nine heads are given under which a patent would be considered "*bad*," but they are given in such a way as to convey the impression that a "bad" patent is a *worthless* patent. Now, this is not so. Everyone of these bad points can be amended after sealing of the patent, and so it can be made a "good" one. Further, an unnecessary piece of advice is given, that, when an inventor has drawn up his specification, with drawings, to the best of his ability, "he should *at once*, as he will *then* be in the position to do so, institute a most *careful* and analytical search through all the specifications *relating to the subject*, in order to ascertain how far his invention or improvement is novel, and how far it is not novel, so that he may protect himself and define and obtain his rights by lodging *proper documents*." What "proper documents" is he to "lodge," I wonder? What is to prevent someone else, either in this country or any other in the International Union, from applying for a patent and taking priority over him while the inventor is making his "most *careful* and *analytical* search?" and how is he to examine anything on which a patent has been applied for, *anywhere in the world*, for ten months previously, which will, perhaps, render his patent void through anticipating his invention?

It is implied that this searching should be done by a properly qualified, professional patent agent, therefore I am not at all surprised that it is not said or hinted how or where a search can be made; I will, however, supply the omission further on.

It is hardly fair to say, "that apparently the best qualification for employment in the Patent Office is the least possible acquaintance with, if not a total ignorance of, all matters relating to patents and the kind of work that has to be performed." No doubt this "thrust" at the Patent Office has been given because the officials try honestly to carry out the Act of 1883, and do all they can to assist inventors applying for their own patents. This has been a very sore grievance with professional patent agents, and they got the thin end of the wedge in, with the Act of 1888, which provides for the registering of the present and the exclusion of new patent agents, as well as giving the Comptroller power to reject specifications if not drawn up properly, instead of sending them back to be amended; but as the Act says he "may" do so, and does not say he *must*, I have not heard of any being "rejected," but all are sent back to be altered, if anything amiss is found in them. As it is, instead of charging the officials with "ignorance" or incapacity, I think they are wonderfully well trained for their work, considering the vast variety of subjects they have to deal with.

When anyone has invented anything they consider of value, and they have reason to believe it is *new*, the very first thing they should do, is to apply for a patent, and lodge a "provisional" specification (forms A and B cost £1). The first thing to consider and decide on is the Title, or name to give the invention, which must indicate the *nature* or subject of the invention. The Act of 1883 says only one invention can be included in one patent, but it also says, the validity of a patent must not be questioned on the ground that more than one invention is covered by it; hence, if the title is made wide enough, so as to embrace a whole host of things, they can be all included in one patent—patent agents do *not* point this out to their clients—thus you can call your invention "Improvements in Domestic or Household Implements or Applianees," and proceed to describe improvements in sewing, washing, wringing, or knife-cleaning machines, or any other thing used in the house; or, under the title of "Improvements in Agricultural Machinery and Appliances," you can protect improvements in every kind of machine or tool used in the farming industry; care being taken, in the specification, to call it *one* invention, simply dividing it into *parts*: for instance—the first part of this invention relates to improvements in reaping machines, etc.; the second part of this invention relates to improvements in thrashing machines, etc., and so on.

The Provisional Specification should only describe the *nature* of the invention; the more brief and vague it is the better. "C. C. C.'s" instruction to draw it out in full, as if a "Complete" Specification, is, I venture to think, a point on which he has "gone wrong," though drawing it in the manner he advises would not render it void, but it does lay the patent open to objection, as there is nine months to complete it in, during which time any improvements can be added, and claimed in the Complete Specification. Now, if in the meantime someone else should apply for a patent on the same thing, and his particular development of the invention is in the complete one, and not in the provisional, it is open for him to say it was got from him, and that if a patent was granted it should be only on the lines of the "Provisional." I don't know that he would succeed, though Sec. 4 of the Act of 1888 says he shall—the point has not been decided—but it is a debatable question, and might mean a lot of trouble and worry; while if the invention is only *described* in general terms, without drawings, it would be next to impossible to say the invention set forth in the Complete Specification was different to what is described in the Provisional.

Now, while only a short description is necessary in the Provisional Specification, a full description, full and sufficient directions for performing or carrying into operation, and a full statement of claims, with drawings, if necessary, must be given in the Complete Specification. In a properly drawn Specification, all three of these conditions or requirements are drawn separately, but as it seldom happens that a new thing requires a totally new mode of performing it, it is mostly sufficient to describe an invention, and direct in what manner it is to be performed, jumbled up together, as such a course saves paper and writing. The statement of claims *always* comes last.

The only conditions to be observed in drawing up a Complete Specification is to state clearly what you mean, avoiding all use of legal phrases. The simpler and clearer it is drawn the better; describe the invention clearly, pointing out the parts that are new and those that are old; then describe how to perform it—that is how to make or use, in such a way that anyone acquainted with the subject can, from the Specification alone, go and make, or perform the same. It is not necessary if a part is to be cast or turned in a lathe, etc., to explain how to cast or turn, unless something peculiar is to be done that an ordinary caster or turner would not know of.

It was said by two of the writers named above, that such should be so drawn and explained that at any future time, "any person" from them alone can make the article or perform the process. This is not so; it is quite sufficient if you merely

describe how the *new parts* are to be performed; you can even assume that everyone knows all about something described in a patent just granted.

The claims should also be clearly stated, and it is better to claim too much than too little, as it is much easier to disclaim than to make new claims. In claiming, all new parts can be claimed separately, so as to prevent such being used by anyone else; and such parts can be claimed in combination with old parts.

If all these are done clearly, and in such a manner that your *meaning* is clear, you have done all that the Patent Laws—not "Patent Office" please, as given by "C. C. C."—require. "The most experienced patent agent can do no more"; and such a Specification will always pass unscathed through the Law Courts on the question of drawing up. There are, however, a great many matters that affect the validity of a patent outside the question of drawing—that were not touched on by "C. C. C."—that require to be understood by every inventor, chief of which is the meaning and effect of the various terms used. I will take first:

*Provisional Protection:* its meaning, use, and effect. Before the year 1884 we had to lodge a Provisional Specification with our application for a patent, which was granted on such Application and Specification, on condition that a Complete Specification was filed within six months. We thus got our patent almost first, and we held all the rights of a patentee. But as the contract with the Crown was for what was described in such Provisional Specification, we could not insert or claim anything in the Complete one that was not mentioned in it. That has all been altered by the Act of 1883. We now get our patent on the "Complete" Specification, the Provisional one merely taking the place of the Caveat, under the old law, and by retaining the same appellation causes so much confusion. Few people seem to know or have any idea why the present form of Provisional Protection exists, or its real value to an inventor. Before the passing of the Act of 1883, very many complaints were made about the injustice suffered by inventors, in this country, in comparison with the United States of America. In that country an inventor has two years, after first publication, in which to apply for a patent: this gives him a chance to perfect his invention before patenting it; while in this country he could neither previously make it public or improve it, after applying for his patent. Several Commissions were appointed by Parliament to inquire into, and report on, the United States Patent Laws, and such Commissions pointed out that inventors in that country suffered very greatly, inasmuch as the *first* inventor alone had the *right* to the patent, and this without any regard as to when he invented the matter; so that if an invention proved to be valuable, the Law Courts were occupied for years deciding the claims of the various claimants. Some have run twenty years: notably the "Drive Well" patent; while the Telephone patent has been in the Courts testing its validity ever since it was invented. And as the temptation to copy a known invention, and bring up witnesses to swear to it, is very great, when a large sum of money is at stake, and the difficulties of detecting such frauds, it was agreed that such a principle could not be adopted in this country; therefore, while adhering to the strictly English principle of "first come, first served," it was provided in the Act of 1883 that when a person has conceived the idea or outline simply of an invention, he can apply for a patent, lodging simply a Provisional Specification, to enable the Comptroller to identify the invention with the Complete Specification. He then becomes provisionally protected—that is, as his patent is dated from the day of application, he takes priority over all other subsequent applicants; and Sec. 14 protects him from the consequence of publication or piracy, providing a Complete Specification is lodged within nine months, or ten months for £2 extra. Now, while this Provisional Protection gives the inventor no patent rights whatever—which "Patentee," page 574, contends it does—it protects the inventor in a very material manner: first, it gives him nine months to perfect, test, and mature his invention; secondly, it assures him a patent against all comers; and thirdly, it gives him seven months' Provisional Protection in the United States of America, and almost every other civilised country that has Patent Laws, all for the one fee of £1, payable to the British Patent Office. In all the countries comprised in the International Union, patentees have the same rights they have here, but of course they must apply for patents, if they want them, in those countries within seven months; but when they do so, they can have their patents dated back to the same day as the British one, and thus take priority over any subsequent applicant even in his own country. Foreign inventors have the same privileges or rights here, and not a few have already walked over British inventors; so while £1 will make an invention as safe as it is possible to make it, by following the advice given to first "search" at a cost of 21s. a day, an inventor may be forestalled. If an inventor feels safe about his invention at the end of nine months, he can abandon the first one and lodge another application, with a Provisional Specification, providing he has not made the invention *public*, which is termed:

*Public Use or Knowledge.*—This is quite sufficient to invalidate a patent, no matter how drawn. The principle on which this works, is that if an inventor makes his invention known to the public, there is no need to grant or offer him a patent to induce him to make public his invention—it would be equal to making one a present and then asking for payment. Nor is a man entitled to a patent for what the public already knows of, uses, or can get to know in this country; but such publication must disclose sufficient knowledge how to make or perform the invention to one who understands the subject. If the invention is an article put on the market in the way of trade, it may be assumed that all who get one, can take it to pieces and copy it; but if no one has had such an opportunity, and that it would be impossible to make sueh articles or perform the invention, there is no publication such as is necessary to invalidate a patent: not even if the very identical articles are described in a patent specification; for bear in mind the patent is granted in exchange for the disclosure of a *practical* mode of performing the invention, so that if no practical mode is disclosed of performing or producing the invention, the patent will not only be void, but it will not operate as an anticipation of a subsequent patent that does disclose a practical mode. This question was settled in the House of Lords (see "Betts *v.* Menziers," 10 H. L. C., 117). So what an inventor should do when he finds a prior patent has been taken out for his invention, is to examine if the disclosed mode of performing it is practical; if not, he can claim everything shown in it, as a just reward for his *practical* mode. As a great many patents are only for "paper" inventions—that is, inventions that have never been worked or tested in a practical manner—the chances are great that they are failures, *i.e.*, impracticable. Some people also consider that *ideas* are inventions and patentable. An invention may be, and often is, the result of an "idea," but it must be a realised result, with all the details of carrying it out, so as to serve a useful purpose. If it fails in this, it is no "invention," or patentable, so that an inventor can get his "ideas" from anywhere he likes.

*Utility.*—This also is necessary to support a valid patent—that is, it must serve some useful purpose. It is often set up as a plea against a patent that is being worked, which is absurd, as the mere fact of its being *worked* is proof that it is "useful"; but it is a good defence against an impracticable patent, the owner of which is trying to levy blackmail, under the charge of infringement, on a subsequently successful and useful patent.

*First and True Inventor.* — This is a matter on which a great deal of misconception prevails, especially as it means one thing in this country and another in America. In the United States, it means the first person who actually works or produces the invention. It really means in law, the person who first conceives the idea, but the Courts draw the line as above, as it would be absolutely impossible to test a man's *mere word* in any way, so that the Patent Laws would have been a farce. In this country, it means the first person who imports it from abroad, no matter how he obtained it, or who in this country having *bonâ fide* invented it himself, *first applies for a patent on it.* If he has obtained the invention by fraud, or "picked it up," being the invention of someone else in the United Kingdom, he is not the first and true inventor, nor entitled to a patent. Thus, if he is an honest inventor, or importer, and is the *first* who applies, he takes priority over all others, no matter how long they have been keeping their inventions secret.

I must reserve further remarks for another and concluding paper.

## MEANS, MODES, AND METHODS.

### To Raise Bruises in Wood.

Often in working soft wood, such as pine, etc., anything falling on it, or it getting knocked, produces a nasty bruise, which to plane out would reduce the wood, and, in many cases, would not be practicable. It is not generally known that bruises can be raised up again level with the surface by pouring in the hollow "produced by the bruise" methylated spirit, and setting it on fire, not allowing it to burn itself out, but blowing it out before the spirit is exhausted (or it will burn the wood). It will be found in most cases that the bruise has come up level with the surface; but if badly knocked or bruised, it will require more than one application of spirit, always blowing out the light after the spirit is burnt away. Bruises of nearly every description can be raised in this way. H. H.

### A Safe Way of Hanging Pictures.

Occurrences are frequently being recorded of the falling of framed pictures, and the narrow escapes of bodily injury therefrom. Lately, a picture fell in an undesirable way in a room of the house wherein I live; a small boy fortunately having, the moment previously, passed over the spot whereon it fell.

From this and similar incidents, I have been induced to give my humble attention to some simple means of preventing, as far as is possible, the likelihood of an accident occurring to any precious member of what we are told is the evolutionised ape family.

As the method I have adopted is simple, and requires so little extra labour, no reason remains why it should not be given a trial. It consists of nothing more than the use of *two* cords, or a single cord doubled to answer the purpose of two, instead of the use of but one cord. Fig. 2 gives a back view of a frame supported in such a manner, and Fig. 1 a side view of the same. If the rings are large enough, by all means have two cords; if not, then it will be sufficient to carry one cord through and tie it around each ring and to itself.

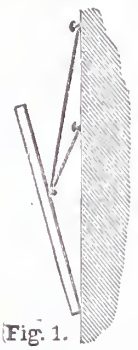

Fig. 1.

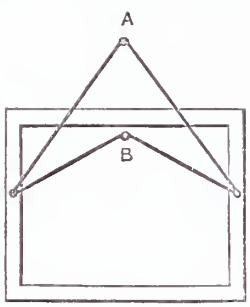

Fig. 2.

**Fig. 1.—Side Elevation of Picture and Cords. Fig. 2.—Back Elevation of ditto.**

Difficulty will be experienced in hanging pictures thus, as I can testify from personal trials. Perhaps the best way will be to use a prop whose length shall be sufficient to allow enough to project beyond the bottom of the picture to handle, while its top end is in contact with the lower loop for the purpose of hitching it on to its destined nail. To ascertain the accurate distance to fix the two nails apart from each other, place the two loops of the frame as in Fig. 2, and measure the length of the space between points A and B.

If pictures are supported in this manner, the top cord will be relieved from bearing so much weight as it would otherwise be compelled to; but should it chance to break, the lower cord will prevent the picture from falling, and *vice versâ*. J. S.

### To Clean Glass.

An excellent way to clean glass, especially adapted for picture glasses, glass cases, windows, etc., is as follows:—Procure a *clean* bottle, and put in one part of strong ammonia, and add about eight parts of *clean* water. Cut a groove down one side of the cork, and, replacing it in the bottle, we have a supply of liquid, which can at any time be sprinkled on the glass we wish to clean. If the glass is very dirty, we shall want two dusters, and sprinkling a little of the liquid on the glass, and wiping it with a duster, the dirt, etc., will be easily removed; after which, a few more drops sprinkled on and a clean duster, the glass will clean and polish up beautifully. H. H.

## MASONS' WORK.

BY MUNIO.

Tools and Appliances used in Masons' Work — Scaffolding — Hoists and Cranes — Centres—Mortar, Cement, and Concrete —Foundations—Setting Out.

**Tools and Appliances used in Masons' Work.**—The tools used in masons' work are the walling hammer (Fig. 10), for hammering and dressing walling stones; the trowel (Fig. 11), for spreading the mortar; the jointer (Fig. 12), for drawing the joints, and for tuck-pointing. A bit-hammer is also used for dressing stones. It is a short hammer, with a mortise hole at one or both ends, into which bits of various shapes can be fixed. A kevel, which is a hammer similar to a walling hammer, but much larger, is used for cutting and breaking up stones. Iron wedges of various sizes are used for cutting stones; they are fixed in grooves, and struck by the kevel. The points of the wedges should not touch the bottom of the groove, or they will fly out when struck; and, to get a clean cut, a crowbar should be laid solidly under the stone.

A plumb-rule is used for plumbing angles; a level for levelling stones; a line for walling; and straight-edges and rules of various sizes are used, but these need no description.

The mallet (Fig. 13) is used for dressing stones; the point (Fig. 14) is used to knock the rough off stones; the chisel (Fig. 15) is used for drafting: they are made from $\frac{1}{4}$ in. to 1 in. broad; the boaster (Fig. 16) is used to level the surface of a stone; a broad tool, similar to a boaster, but $3\frac{1}{2}$ in. or 4 in. wide, is used for tooling. The hammer and punch (Fig. 17) are used for roughing off hard stone; the pitching tool (Fig. 18) is used to knock off the edge of a stone to a line: it is only used on hard stone; the claw tool (Fig. 19) is used on limestone and marble; the lead mallet and lettering tool (Fig. 20) are used for cutting letters: the tool is $\frac{1}{2}$ in. in diameter at its widest part, and the edge is spread out; they are made in various sizes.

The chisels are sharped in a smith's fire, and are tempered to various degrees of hardness. For soft stones they are drawn out thin, and made moderately hard; for hard stone they are not drawn out so much, and tempered harder. After being sharped, the edges are rubbed on a stone till quite straight. The mason ought to learn to sharp his own tools.

The drag (Fig. 21) is used for levelling down the rough in Bath stone; it is a piece of steel plate, with teeth on one side; they are made of various forms, and with teeth of different degrees of fineness. Teeth saws are used on Bath stone and magnesian limestone. Plate saws without teeth are used on Portland stone, marble, and granite: they are fed with coarse sand and water. For sawing large blocks, tooth and plate saws, from 5 ft. to 7 ft. long, are used: they are fixed in frames similar to a joiner's turning saw; the frame is suspended by a rope passing over a pulley, with a balance weight at the opposite end. A handle is fixed at each end of the frame, and the saw is worked by two men. A groove is cut as a guide for commencing saw-cut.

In large works, steam-sawing, dressing, and moulding machines are used. Marble and granite, after being sawn, are polished with large cast-iron plates, fed with sand and water, which are revolved upon them; these plates are called laps.

The stone-pick (Fig. 22) is used for broaching. A hammer, called a diamond hammer, is also used for broaching. It has six or more steel points fixed in mortise holes in the face, and is hammered over the face of the stone.

The granite hammer (Fig. 23) is used for knocking up granite; it is also dressed by the mallet and chisels, and axed by a tool similar to a short thick hammer with a broad point, called an axe.

Squares, bevels, straight and circular rules of various kinds, are used for marking stones, a piece of hard black shale called "black," or thin pieces of hematite iron ore, being used to draw the lines. Measuring laths, gauges, zinc and wood moulds, iron crowbars, and rollers are also used.

The Lewis (Fig. 24) is used for hoisting stones. It is in four pieces, fixed together by a pin and cotter. A dovetailed hole is cut in the stones, in which it is fixed. Clips or grips are also used for hoisting. They consist of two large hooks, with a ring fixed in each. They are connected together by a chain passing through the rings. The hooks are let into holes at each end of the stone, and the tendency of the chain pulls the hooks together, and causes them to grip the stone.

**Scaffolding.**—The scaffolding used for ordinary works is made with poles 20 ft. to 30 ft. long, fixed 10 ft. to 12 ft. apart. Ledgers are fixed horizontally to the poles by scaffold cords; the ledgers are 7 in. by $2\frac{1}{2}$ in. On these are laid the putlogs, which are $5\frac{1}{2}$ in. by 3 in., with one end resting on the wall. On these are laid the scaffold boards, which are deals, 9 in. by 3 in.

**Hoists and Cranes.**—For hoisting stones up to $\frac{1}{2}$ ton in weight, ledgers are fixed about 10 ft. above the scaffold at both sides, and resting across these a strong frame about 9 in. wide is laid. An iron rail or bar is fixed on the top of the frame at each side, and a carriage with four grooved wheels runs on the rails. To this a pair of pulley-blocks is hung, by which the stone is lifted, and is run to its place on the wall by the carriage. The rails are turned up at each end, to prevent the carriage running off.

For heavier stones, shear legs are used. They are made of strong poles, 20 ft. to 30 ft. long. They are lashed together at the top, and the bottom ends spread out 10 ft. or 12 ft. They are kept perpendicular by two long guy ropes fastened to the top, and put round posts let into the ground at the bottom. A pair of pulley-blocks with a fall rope or chain is slung from the top, and the weight is raised by a crab-winch (Fig. 25). In order to take the strain of the guy ropes, the rope is brought round a block fixed at the foot of one of the legs, called a "snatch-block" (Fig. 26).

When a building is of great length, a hoist similar to Fig. 27 is used. This is made of squared timber fixed on a strong frame, in which two grooved wheels are fixed. These run on a single iron rail, laid the full length of the building. A cross-head, with a pulley at each end, is fixed on the top, over which the fall rope passes. A crab is fixed on the frame for hoisting, and the hoist is kept perpendicular by two guy ropes. Sometimes a small steam hoist is fixed on the frame instead of the crab.

Derrick cranes (Fig 28) are also used for hoisting. They are fixed inside the building, and the jib is arranged to sweep round the walls. When the building is too large for one jib to reach round, two or more are used. They are fixed on the various floors as the building is carried up.

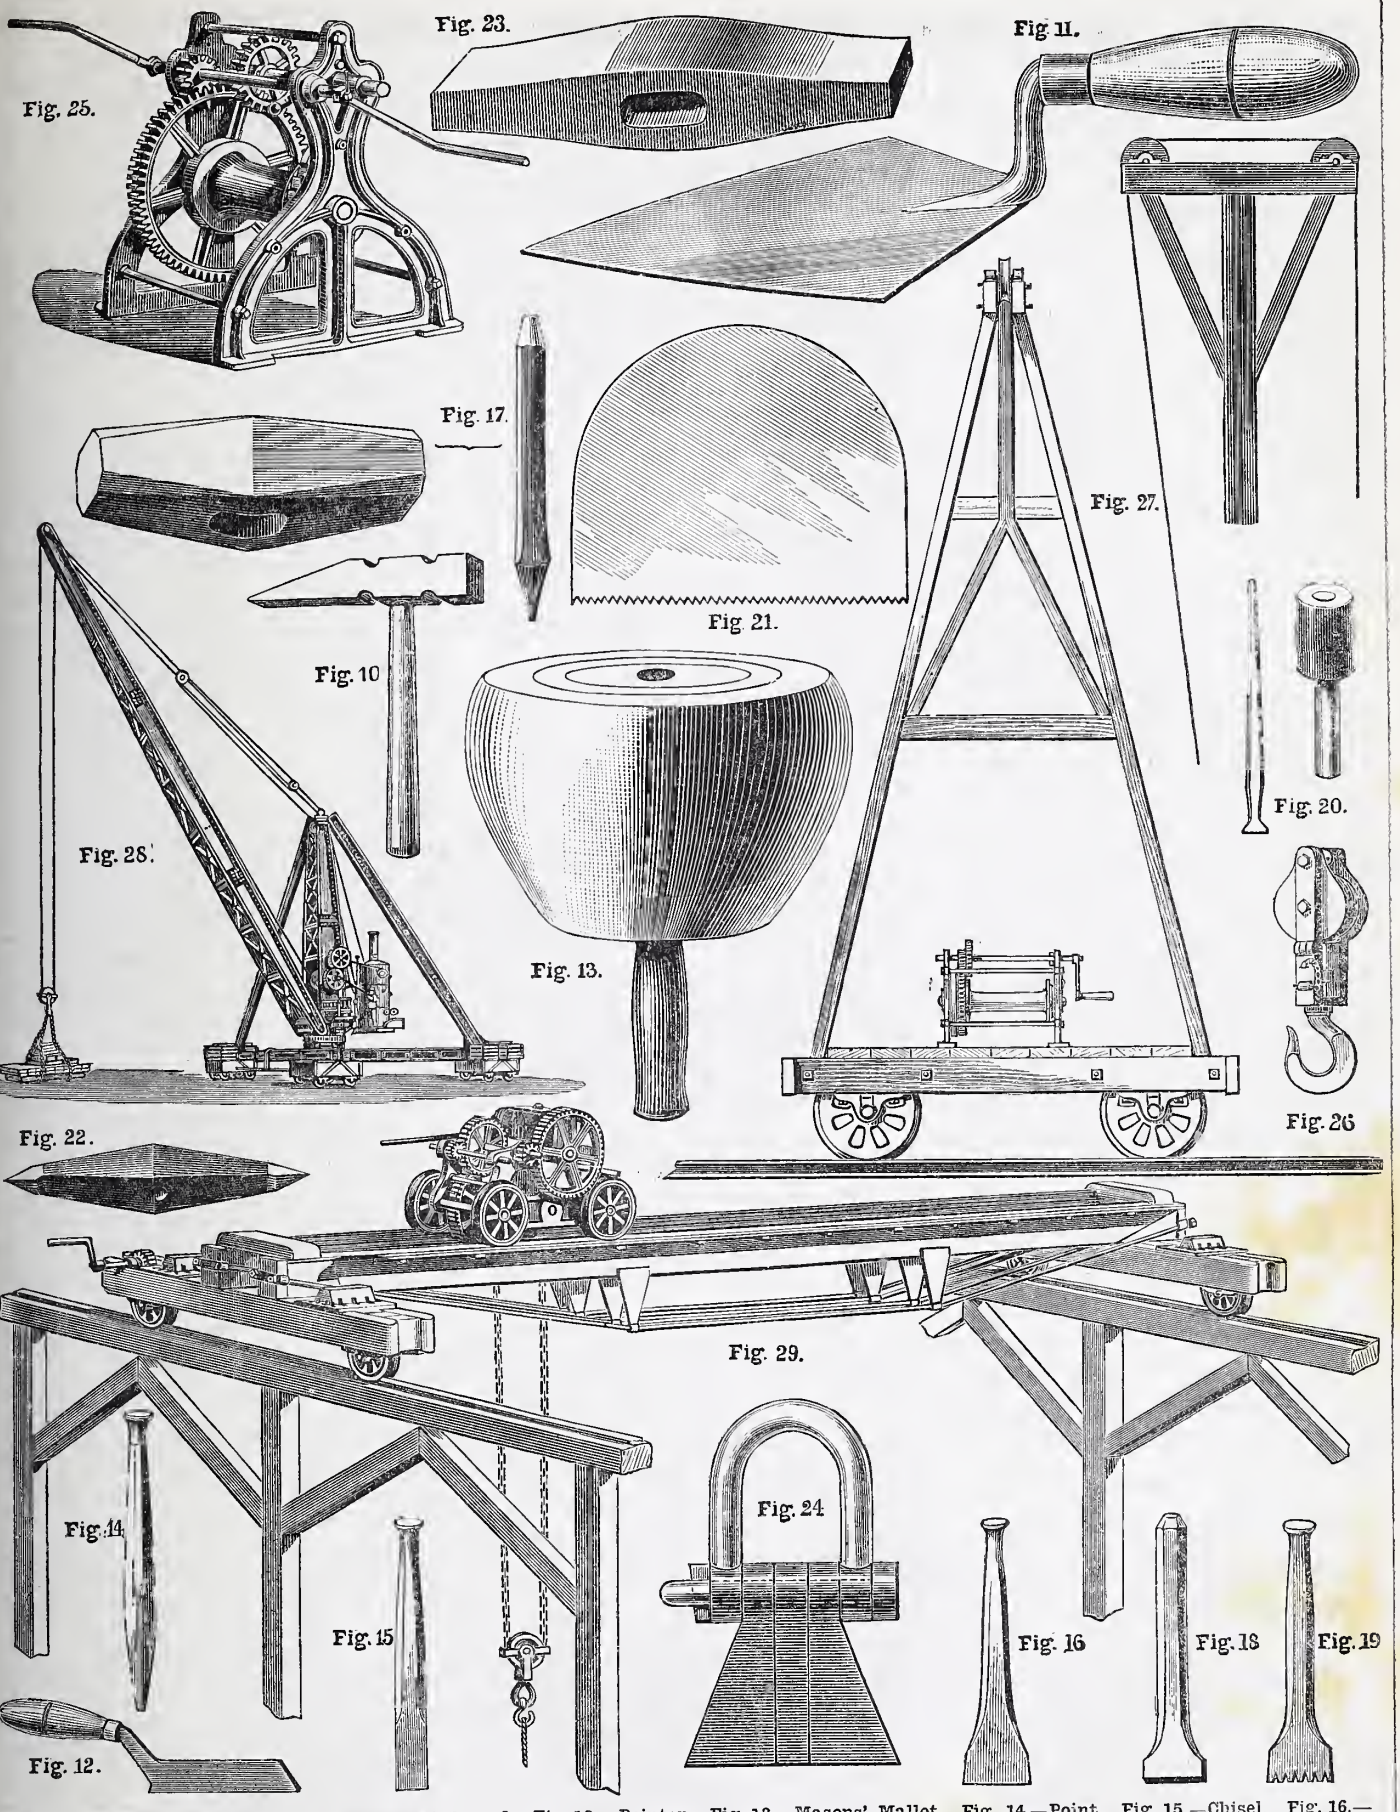

Fig. 10.—Walling Hammer. Fig. 11.—Masons' Trowel. Fig. 12.—Pointer. Fig. 13.—Masons' Mallet. Fig. 14.—Point. Fig. 15.—Chisel. Fig. 16.—Boaster. Fig. 17.—Hammer and Punch. Fig. 18.—Pitching Tool. Fig. 19.—Claw Tool. Fig. 20.—Lead Mallet and Lettering Tool. Fig. 21.—Masons' Drag. Fig. 22.—Stone-Pick. Fig. 23.—Granite Hammer. Fig. 24.—Lewis. Fig. 25.—Double Purchase Crab-Winch. Fig. 26.—Snatch-Block. Fig. 27.—Hoist. Fig. 28.—Derrick Crane. Fig. 29.—Overhead Travelling Crane.

When a building is very large, and the stones are of great weight, the overhead travelling crane (Fig. 29) is used. It is mounted on iron rails laid on strong timber framing, formed of baulks 12 in. square, and strongly braced and stayed. The crane is moved lengthways by gear wheels, and the crab on the top is either moved by gear wheels or pushed by the men walking on the platform. The framing is generally fixed half the height of the building at first; and when the building is brought up to that level, it is raised.

**Centres.**—Centres are also used by masons for turning arches. Those for bridges, or arches of large span, must be very strongly made, and fixed on firm supports. In all cases, wedges, or some means of slacking the centres as soon as the arch is keyed, should be provided; and in removing large centres, the ribs should be well stayed, as many serious accidents have occurred when the centres were suddenly released.

**Mortar, Cement, and Concrete.**—The mortar, cement, and concrete used in masons' work is similar to that used by bricklayers, and is fully described on page 183, Vol. II.

**Foundations.**—The foundations for walls should be neatly squared out, and the bottom made level. When the ground has an inclination or slope, the foundations should be "stepped," and the bottom of the trenches kept level. A drain should be laid from the lowest point of the foundation, to carry off the water. When soft or wet places occur in the foundation, the trench should be carried down to firm earth, and filled with concrete, and a drain laid to carry off the water. In large buildings a bed of concrete is often laid over the whole of the foundations, on which the footings are laid. The turf and vegetable soil should be taken off the whole of the interior of the site; and where wood floors are laid, a layer of concrete or asphalte should be laid over the surface, to prevent damp arising.

Excavations for cellars, basements, etc., should be accurately marked out, and squared down to the bottom, and a drain laid from the lowest point, to clear them of water. After the walls are built above the surface of the ground, the trenches should be filled in, and well rammed down.

**Setting Out.**—In setting out a building, centre lines should be stretched both ways. These should be accurately squared, and fixed in saw notches cut in the tops of pegs driven well down; all walls can then be gauged from these. Interior walls should all be gauged from the centre lines, and not from each other, so that any error may be more easily detected.

A fixed level should also be set up. This may be the floor or base line, and all levels may be taken from it.

## OUR GUIDE TO GOOD THINGS.

*** *Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of anyone who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

### 26.—"ARDENBRITE" LIQUID GOLD.

If any reader is inclined to ask what "Ardenbrite" is, I can tell him that it is a duly registered trade mark, and a distinguishing name applied to some excellent so-called liquid gold, metallic enamels, and metallic paints used for decorative purposes, and manufactured by Messrs. T. Pavitt and Sons, 70, Southampton Row, London, W.C. If I am further asked the derivation and meaning of the term, I can only reply that I believe it to be an imposing, but at the same time playful, way of disguising the Queen's English by making "hard and bright" appear as one word "Ardenbrite," inasmuch as the words which may be assumed to be its original source fairly describe the durable and brilliant qualities of the materials to which it is applied. To take the three principal forms of Ardenbrite in order, the "Ardenbrite" Liquid Gold, which, if I remember rightly, is the oldest of the three, does not tarnish, and washes well; its makers claiming for it that it lasts three times as long as real gold leaf. Be this as it may, its effect is brilliant, and the surface, when hard and dry, presents a highly finished appearance. It is very generally used by the trade for decorative purposes in theatres, tea-rooms, and public places of resort, and by the principal railway companies in the United Kingdom, and the most important lines of ocean steamers. To those who do any painting and decorative work at home it will prove invaluable. It can be applied with excellent effect to any material whatever, even to leather, for it is much used for decorating and renovating ladies' slippers in its various colours—gold, silver, red, and green. It may be obtained of all artists' colourmen, chemists, oilmen, etc., in jars at 6d., 1s., 1s. 6d., and 2s. 6d. It is used without any preparation beyond stirring it well up, and it can be applied with an ordinary paint-brush. For trade prices, application should be made to Messrs. Pavitt & Sons. The liquid enamels manufactured by Messrs. Pavitt & Sons are another form of Ardenbrite. These are sent out in gold, silver, copper, green, steel, and red; and by their aid the surface of any material can be quickly covered with a brilliant coating of metallic enamel which dries within half an hour; and which, when perfectly dry, is permanent and washable, and requires no varnishing. It can be applied over paint or varnish without removing the old coating. Last in order come the Ardenbrite Enamel Paints, which are supplied in white, vermilion, blue, sage-green, primrose, and black. These are said to produce by the application of two coats a surface like china, which dries perfectly hard in six hours. I think I may fairly say that those who use Ardenbrite in any or all of its three forms will not fail to be satisfied with it.

### 27.—WOOLHOUSE'S "MEASURES, WEIGHTS, AND MONEYS OF ALL NATIONS."

This is the seventh edition of a book that I have used for purposes of reference for many years, and I am glad to meet with it again in its revised and amended form. It was written originally by Mr. W. S. B. Woolhouse, F.R.A.S., F.S.S., etc., and is published by Messrs. Crosby Lockwood & Co., Stationers' Hall Court, Ludgate Hill, E.C. It supplies the means of readily converting the standard, linear, and square measures of one country into another, as well as the measures, weights, and moneys of all nationalities, and "the comprehensive principles which influence the fluctuations of exchange are also briefly stated, and correct rules given for computing the sterling value of coins and bullion. Not the least valuable portion of its pages are those devoted to an exposition of the measures of time, pertaining to the Gregorian, Hebrew, and Mahometan calendars, with a table of the principal epochs. To almanack makers this portion will prove especially useful. Besides a large variety of miscellaneous and interesting information on other matters, the Appendix gives particulars of the new Weights and Measures Act, 1889; a reliable account of the weights and measures of Japan and China; and full and authentic information on the subjects of Wire and Plate Gauges, and, more especially, in relation to the new Imperial Standard Wire Gauge, which was legalised by an Order in Council in 1883. The volume, which forms one of Weale's Rudimentary Series, has been much improved by being issued in a neat cloth binding—a considerable improvement on the old style, in which the edges of the boards of the cover were flush with the edges of the paper.

### 28.—SCREWS AND SCREW-MAKING.

Nothing seems to come amiss to the Britannia Company, Colchester, which, not content with a good reputation for making engineers' tools and appliances, and lathes and machinery of every description, seeks to do a large second-hand trade in goods of the same class, and, lastly, to pose as the publishers of some strictly technical works. The latest of those is a book entitled "Screws and Screw-Making," with a chapter on the milling machine. It claims to be "a complete treatise on screw-making in all its branches, embracing most recent methods, and containing the reports which originated modern standard screw-threads." The nature of the work will be best understood from a brief summary of its contents. After a preliminary chapter showing the different kinds of screw-threads now in use, the writer proceeds to describe the Whitworth, American and Swiss systems of screws, and the British Association screws. This is followed by instructions and remarks on chasing screws by hand, screw-plates, dies, and taps, and cutting screws on the lathe. Then comes the consideration of arithmetical rules for calculating wheels, a table of change-wheels for screw-cutting, and an explanation of the difference between, and mode of cutting screw or spiral wheels and worm wheels. The volume is brought to a close with remarks on screw-making, various tables of screws, and an account of the milling machine and some of its best types, as stated above. The work has a good though not very copious index, and is rendered all the more valuable by having bound up with it about 104 pages, which contain notices and engravings of the leading specialities of the Company, and form as good a price list of the Company's tools, machines, and appliances as any man need have. I must not omit to say that the price of the book is 3s. The writer has done his best to collect and epitomise all necessary information on the subject; and those who desire to make it their study, either for acquiring a knowledge of it for trade purposes or for competitive examinations, will not fail to find the volume, as far as I can judge from a cursory examination of it, both useful and reliable.

### 29.—PATENT SIMPLEX FIRE ESCAPE.

The fire escape that bears this name has been patented by Mr. William Petty, 4, Straithmartine Terrace, Drayton Road, Leytonstone, Essex, who makes the apparatus, and will supply it and fit it up in the houses of those who may wish to avail themselves of the means of escape it affords in cases of fire, when it is impossible to quit the house in the ordinary way, and egress must be sought through an upper window. The escape itself consists of a long canvas shoot or bag, open at the upper end, and having another opening near the bottom. The lower end is closed by an ornamental metal disc and locking gear, the purpose of which will appear presently. This bag, when compressed into its smallest compass, is contained in a metal case, which is placed in the ceiling of the room in which it is to be used, between two joists that are immediately over the window. Thus it lies completely out of sight, the only visible sign of its presence being the metal disc with which the opening in the ceiling is closed. The upper end is attached to a stout and strong piece of rope, whose other end is securely fastened to the joist. Should there be occasion to make use of it, the only thing to be done is to throw up the lower sash of the window and pull the cord attached to the disc in the ceiling. This brings out the bag, which must be thrown through the window, and is caught and held steady by someone standing below. The mode of descent is to enter the bag at the top and slip down it to the opening at the bottom, whence an easy exit is obtained. The bag itself is made of fireproof canvas, so that it cannot be injured by flames issuing from the house below the window from which it has been thrown. For nervous or frightened women or children it seems to afford a safe means of escape.

THE EDITOR.

### I.—Letter from a Correspondent.

**Rate of Circular Saws.**—A Woodworker writes:—"If a man lays out £10 or £12 in a machine, he expects that machine to turn out an extra amount of work to repay him. Therefore, when a man buys a hand-power circular-saw bench, he expects more work done with it than with a hand rip saw; and as I think the speed of a circular saw and feed of timber may be reduced in proportion to the power, and be an advantage, we will try, as briefly as possible, to see what advantage there is in a circular saw being driven by hand over a hand rip saw. The standard speed of a circular saw driven by steam and other power is about 3,000 revolutions per 12 in. saw per minute; and the rate of feed in cutting timber one-third its diameter, about 15 ft. per minute; and the power required, near 1½ H.P. Now a man, being calculated to be about ¼ of a H.P., turns a wheel 4 ft. or 5 ft. in diameter at the rate of 30 revolutions per minute, which is a good speed for a man to turn. From this wheel a 12 in. circular saw is driven, the speed multiplied 10 to 1; that is to say, the saw makes 10 revolutions to 1 of the wheel: then 10 times 30 is 300, the number of revolutions the saw makes in a minute, which would be ⅓th the speed of the saw driven by steam power. Now then, if the feed of timber to the saw driven at 3,000 revolutions is 15 ft. per minute, the feed of the timber should not be more than ⅒th of that with a saw running 300 revolutions per minute, which would be at the rate of 18 in. per minute. Again, in calculating 8 men to 1 H.P., and 1½ H.P. being required to drive a 12 in. circular saw at the above speed and feed, a man would be but ⅛th of that power; therefore the feed needs to be reduced at least to ⅓th of 15 ft., which would be 15 in. per minute. Again, when a saw is driven by steam, by keeping the steam up to a certain pressure the same power may be maintained for any length of time. But it is not so with a man; after turning the wheel a short time his strength diminishes, and the power exhausted is not more than ⅛th, and perhaps much less when the rate of feed has to be reduced in proportion, the feed being 12 in., and perhaps much less, per minute. Now then, we take a good hand rip saw, properly sharpened, and in a 3 in. deal it should advance at least ½ in. each stroke, making 40 strokes per minute, which is not very fast; it rips 10 in. per minute. But how much easier does the man with the hand saw rip the 10 in. than the man who turns the wheel drive through the 12 in. or 15 in.? The man at the wheel will not turn many minutes before he wants to rest and dry the sweat from his brow, and while he is resting the man with the hand-saw is still at work, at the same time having a civil chat with a friend or shop-mate. Now, taking all things into consideration, I contend that if the hand rip saw is properly worked it has an advantage over the circular saw driven by hand. I should like any reader of Work who is an employer and has a hand circular-saw bench, when he has a deal of ripping to do, say in 3 in. stuff, to get both circular and hand rip saws in good condition, and set two men at work, one at the wheel and the other at the hand saw, and see at the end of three hours which saw has the advantage—neither man to be relieved during the three hours—and report in the 'Shop' corner of Work. It must be remembered, too, that to work the circular saws satisfactorily two men are required."

### II.—Questions Answered by Editor and Staff.

**Lettering on Carts and Waggons.**—C. W. (*Worcester*).—Writing names on carts and waggons is a very simple affair, as plain block letters are generally used for all country rolling stock. I have painted some dozens of railway waggons and carts in times gone by, and I always used ordinary paint, thinned out from time to time with a little turps, as for common work of this kind, and a lot of it to do, speed is everything, and the more simple the diluents the less likely one is apt to go wrong. I think this is where you are in difficulties, as I frequently suffered from the same cause myself. In putting the last coat of paint on the cart or waggon, it is made to contain as much boiled oil as possible, so that it may dry with a good gloss, and also keeps out the weather better. Now, this surface is fatal to good lettering, as the letters will keep "cissing"—*i.e.*, running into ragged edges. This may sometimes be prevented by using nearly all turps in the colour you are writing with, by rubbing the surface with a little turps or by wetting with a leather. If this will not rectify, then repaint the part where letters are to go, write them, and when dry, varnish. If your paint runs down your brush, you either use it too thin or you are using long lining pencils instead of writing pencils, or you get your pencils too full. Do not dip your pencils into a pot of paint—rub some out on a piece of glass, and take the colour off of there.—H. L. B.

**Staining Walking Sticks.**—H. S. (*Graffham*). You do not say what colour you wish to stain your sticks of holly, hazel, and ash, or whether you have stripped off the bark or retain it. I can only presume that you have stripped off the bark, and wish them stained the usual brown or black, then French polished or varnished. A useful brown stain can be made by dissolving 2 oz. of asphaltum in nearly ½ pint of turpentine: give one or more coats with a piece of soft rag, or sponge, till you get the required shade. If this cannot be readily procured, thin some Brunswick black with turps. When dry, French polish, or give several coats of spirit varnish; but I fancy in your case you would find it better to give them a coat or two of patent knotting. For the black sticks, procure some black aniline dye, sold in penny packets, or use black ink; rub well till you have a black ground, then give one or more coats of black enamel. How to make a stick out of a cabbage-stump is, I think, beyond us. If you have a particularly fine one you wish to preserve for ornamental purposes, you might clean and well dry it, then give a coat of some clear varnish, such as copal.—Lifeboat.

**Pantograph.**—T W. (*Sleekburn*).—Apply to any toy dealer or fine art dealer for a Pantograph.

**Cement for Aquarium.**—J. J. B. (*Twickenham*). —See pages 351 and 750, Vol. II.; also Indexes to Vols. I. & II.

**Parlour Clock.**—R. H. (*Accrington*).—The only thing I can suggest is to drill a hole in the case opposite the hour you wish it to ring, stop the hole with a cork, and let the end of a wire from one end of your battery go through the cork sufficiently long enough to catch in the hour hand. You must bend it down so that it does not touch the minute hand; let it lie on the face of the clock, rising from it a little, so that the hour hand must drag over it. Let the other wire from battery go to bell, and wire from bell to one of the legs of clock case; by bending the end of the wire over which the hour hand passes in the direction the hand goes, you can have the bell ring for an hour or more if your battery lasts out. You can buy a bell and battery for a few shillings from any electrician, or you can buy the material and make up your own bell, etc. You will find other methods in back numbers. To stop it ringing, simply disconnect a wire from the bell or battery, and put it on again when you go to bed.—A. B. C.

**Grandfather's Clock.**—Bowton Lad.—If it is only the pivot broken off, you might turn another one on the end and put in a long bush; if it is broken in the middle, the only thing is to put a new piece. The pallets in the old English clocks are often brazed on, and sometimes riveted to a brass collet, which is soft-soldered on the shaft. French clock pallets are generally fitted on a square, and so can easily be shifted, as you say, by gently tapping with a light hammer. The cost of a new pallet shaft will depend entirely where you take it, and may vary from 2s. to 5s.—A. B. C.

**Verge Watch.**—Verge.—I can confidently recommend Messrs. Haswell & Sons, 49 & 50, Spencer Street, Clerkenwell, and Grimshaw & Co., 35, Goswell Road, Clerkenwell, for repairs and conversions. But good verge workers are very scarce, and I doubt where you could get it done as it used to be fifty years ago. Messrs. Haswell converted an old verge for me a few weeks ago, and made a splendid job of it; and although I always do my own verge repairs, I have no doubt they would do it to your satisfaction.—A. B. C.

**Clock Conversion.**—Old Clock.—To make a chime quarter clock from an eight-day English and two twenty-four hour clocks is, in my opinion, an impossible job, as the plates are not large enough for the extra train of wheels; and it is a thousand to one that the wheels and pinions would not be the proper number and size. Then it would require all new dial-work, and unless you have had some previous experience you would find it very complicated. The only thing I can advise is to fix up one of the twenty-four hour movements as a quarter arrangement, as set out in an article in Work some few weeks back. The only drawback is, you would have to wind it every six or seven hours.—A. B. C.

**Lantern.**—E. O. S. (*Rye*).—E. O. S. writes:—"Which is most in fault when a picture shown from a magic lantern is capable of focussing either sharp in the middle or sides, but not the two together, the objective or condenser? Mine is a £6 6s. lantern and lamp."—With a lantern of the price named, and by the maker he has mentioned, E. O. S. ought not to find any very great difficulty under proper conditions. At the same time, the maker does not guarantee the instrument to be in focus in the centre and margin at the same time if a short-focus front-lens is used, for the simple reason that it is impossible. Still, there ought to be a fairly sharp picture. Is it possible that in taking out the lenses to clean them they have been replaced wrongly? If so, then that may account for some confusion of rays. Or has E. O. S. properly adjusted the lamp? There is an exact position, which must be found by trials, where the best definition can be procured. If after every precaution I found the definition hopelessly bad, I should return the instrument to the maker, who, I have no doubt, would properly adjust it.—O. B.

**Bootmaking.**—E. J. S. (*Maidstone*).—This is a subject which will be thoroughly dealt with in the next volume of Work.

**Wood-Carving Patterns.**—W. H. R. (*London, E.*).—The figures in the Index refer to the pages of each issue of Work, and not to the numbers themselves.

**Theatrical Posters.**—A. L. S. (*Glasgow*).—An article is in hand.—H. L. B.

**Graining Cheap Furniture.**—J. M. (*High Harrogate*).—You evidently wish to know how the cheaper kinds of furniture are painted and grained; but, of course, there are many ways in which this is done, in order to bring the goods within the means of people who have but little cash to spare. In the first place, furniture can be painted and grained by the same methods as are used for all other kinds of woodwork; but it is very seldom any high-class work of this kind is put upon furniture, as it is only the cheapest goods which are so treated, as you yourself must know. If you wish to grain in the ordinary way, then the following books will be useful to you: (1) "House Painting, Graining, and Marbling," by E. A. Davidson, 5s. (Crosby Lockwood & Co., London); (2) "The Art of Graining and Imitating Woods," £1 11s. 6d., shortly to be raised to 2 guineas (G. Sutherland, 15, St. Ann Street, Manchester). The latter will be the most complete work ever issued on this subject. I will now describe how the very cheapest kinds of furniture are "got up" in this way, and as it is only known to a few, the process—although I cannot commend it—may prove of general interest, as by the substitution of patent size for oil paint in the first coats, the element of cheapness, as well as a rapid method of manipulating the various processes, is thereby attained. The method consists of mixing up "patent" or glue size with the best gilders' whiting, the size being used moderately strong; this is stained to required shade for the ground colour, such as with venetian red for mahogany, with yellow ochre if for oak, etc., etc. The furniture is coated with this mixture whilst hot, and *is well worked into the wood*. If one coat is not enough, give two. Finish off with a coat of clear size. The graining can now be done upon this in oil colours, rose pink and a little black being mixed with it for mahogany or rosewood; umber and ochre for oak, etc. When it is wished to imitate maple wood, it is best to give the goods one coat of oil paint over the sized surface got up with the priming *white*. It may be thought that this work is not lasting, but it is said to withstand hard wear for years; personally, however, I cannot say, but bedroom furniture, not having much rough usage, is said to last any amount of time. Patent knotting on a sized surface, or the knotting first and size afterwards, in conjunction with enamel colours, is much used in large furniture factories; also the size and whiting process, with one coat of paint on the top for painted furniture. Deal furniture, finished in patent knotting, if carefully done, has a good appearance, and may be either varnished or French-polished afterwards, but for this style the furniture requires to be well made.—H. L. B.

**Wire Blind Writing.**—A. V. W. (*Cheltenham*). —Mark the letters out on the blind in pencil, and then go over them with parchment size; they may then be painted or gilded in the ordinary way. Gold paper letters may be fixed to blinds in the following manner. The gold paper—the best—is coated at the back with strong gum, like postage stamps, but with a much stronger solution. When dry, the letters are drawn, or traced, at the back, and cut out with sharp scissors. They are then wetted at the back and stuck upon the wire gauze, or zinc, the words being previously set out on the blind in the usual manner. The gilt paper may then be varnished over with copal, or any clear, hard-drying varnish, which will enable them to be washed at any time. In varnishing the letters it is necessary to carry the varnish a little over the ledge of the letters, thus preventing the damp from getting at the back of them. (From the "Art and Craft of Sign-Writing.") Wire blinds may be cleaned as follows: Take some methylated spirits in an egg cup, put in a piece of cotton wool, let it soak in the spirit, and set it alight. Then hold the parts of the wire blind over the flame. The old paint may then be brushed off. If the bores of the blind are choked up, remove by inserting a hot needle. When quite clean, varnish with white, hard varnish, and the wood frame with brown, hard varnish. To remove old letters from blinds without injuring the gauze, place that part of the blind which the letters are on upon a piece of wood, so that the gauze lies quite close to the wood. Then apply a solution of *pure* caustic soda with a common fibre brush. A very short time will suffice to destroy the paint and turn it into mud, which must then be washed away with plenty of clean water. The wood beneath the blind confines the solution to that part of the blind only where it is needed, and keeps it from running away.—H. L. B.

**Blow-Lamp.**—Vulcan No. 1.—In reply to your inquiries for a blow-lamp, or self-acting blow-pipe, that will braze ½ in. solid iron, and ¾ in. iron tube, and that will also braze a gold or silver ring, there are several that will do the latter. The one sold by Melhuish, illustrated on the cover of the Exhibition No. of Work, seems well suited for this class of work, but I have not had the opportunity of testing its powers. With regard to the brazing of iron, the

lamp most likely to do that is the Paquelin, fully described in WORK, No. 32, Vol. I., p. 505, and since then mentioned several times in "Shop." I must say that it is a severe test, and I am not at all certain that it would do it. It might under favourable circumstances—that is, that the parts to be brazed be supported on willow charcoal blocks, the work must be somewhere out of colds and draughts, and a deflector held over the top: it might then possibly do it. ⅜ in. iron I know it will do; the ¾ in. pipe would be harder still to do, if you mean gas pipe, and I am very doubtful about it. However, there is no more powerful lamp in the market at present, so it is Hobson's choice—that or none. I may say that the agents advertise it as giving 1,000 degrees of heat (see back page of No. 105, where price and other particulars are given).—R. A.

**Blow-Lamp.**—E. D. (*London, S.E.*).—See reply to VULCAN No. 1 above.—R. A.

**Bottle Lettering.** — FAIT ACCOMPLI. — The names on bottles, lamp glasses, etc., to which you refer, are cast on by the manufacturers at the time the articles are made. An amateur could not do it. —W. E. D.

**Saw Grinding.**—T. J. (*Handsworth*).—If T. J. would write to a good Sheffield saw-maker stating size, thickness, and number of saws he wants made, he would get them cheaper than he could make them. For the size T. J. states the price would be about 3s. or 3s. 6d. each, and as he requires a good number, no doubt he would get them for much less. Of course T. J. will know whether he can make them for less than the above price. There are various methods adopted for grinding saws. One is to place the saw between two revolving grindstones and grind until the hammer marks almost disappear. After which the saw is placed between face-plates, and while revolving is fed with emery. I believe there are improved grinding machines by Messrs. Eadon, Sheffield. By these machines saws are ground to a degree of uniformity which is impossible by other methods. In fact, concave, bevelled, convex, and saws of any pattern can be ground with the above machines to any thickness. —A. R.

**Leather in Binding.**—F. R. H. (*London, N.W.*). —You want me to tell you how to distinguish the difference between Levant morocco, Morocco morocco, and second morocco. Well, I can tell morocco when I see it, but really I cannot give you any information which will enable you to do so. The tooling has nothing to do with it.—G. C.

**Phonograph.**—J. S. (*Newcastle-on-Tyne*).—These instruments are not for sale, but are let out on hire. If you write to the Edison Phonograph Company, 60, Ludgate Hill, London, E.C., you may get some information.—W. D.

**Wax Cylinders.**—X. Y. Z. (*Bradford*).—They are cast in a special mould, which must be of a diameter sufficient to ensure them being slipped on and off the rotating cylinder.—W. D.

**Violin Bridges.**—J. M. (*Newcastle*) and other correspondents wish to purchase COMME IL FAUT'S violin bridge, described in WORK, Vol. II., page 810. COMME IL FAUT should advertise his address, etc., in WORK.

**Bookcase.**—T. M. (*Gateshead-on-Tyne*).—I can only ask you to search diligently the Indexes to Vols. I. and II., for designs of bookcases, in both the body of WORK and "Shop." You can easily adapt fretwork panels if you find a design the general appearance of which you feel satisfied with. See the three prize bookcases in Vol. I.—J. S.

**German Clock.**—J. S. (*No Address*) —See that the hook drops fair in the middle of the notches on the count wheel, and try each one. You may find perhaps that it catches just on the corner dropping in, and so goes on striking, or perhaps the wire that drops down and catches the pin does not drop far enough to catch it safe, or it may perhaps start off striking at the warn. See that when the stopping-pin is freed at the warning that the other wire is up high enough to catch the pin and hold it till they drop at the twelve.—A. B. C.

**Moulding Figures in Plumbago.**—NAP.—I can bring no experience to bear on this question, and doubt whether any other figure moulder could; but, had I the job to do, I should try mixing the plumbago (which would, of course, be in fine powder) with a like quantity of plaster of Paris. But before using the bulk, I should feel my way by experimenting on small quantities; for as a large proportion of plaster would interfere with the appearance of the plumbago, it would be well to use no more than would suffice to make the mixture set firmly.—M. M.

**Circular Saws.**—P. F. (*India*).—If P. F. does not know the whole art of saw hammering, my advice to him is not to attempt to temper his saw or saws. The following information I recently received from a well-known Sheffield saw maker, which will not only answer the question asked by P. F., but will give him and many other readers of WORK such information as will, no doubt, be very acceptable. To make a circular saw that will give satisfaction requires an amount of skill and much labour. The sheet of steel, after being rolled in the rolling mill, is placed between the jaws of a powerful shears and pared to its shape; then the holes are either bored or punched instantaneously with a steam hammer. Then it is put into a toothing machine and the teeth punched; after put into a fiery furnace, and when red-hot, is plunged into a large bath of whale oil—this is termed hardening, in which great care is to be taken. Then it is put into a furnace heated with hot air, and when properly heated, put into the whale oil; then taken out, and if too hard to file, put back into the furnace again and brought to its proper temper. The saw is now ready for the smith, whose duty it is to get the saw level or true by means of hammering. This hammering is done by the most skilled workmen—the art of hammering requiring considerable judgment. After the hammering, the saw is put into the grinding machine and ground to its desired thickness. The saw is further improved by being glazed with a special machine. Another method of tempering saws is to get the saw hot, plunge it into a mixture of oil with suet and wax, then take it out and heat it over a fire till the grease inflames. This process is termed blazing. The saw is then flattened while warm, and subsequently ground. A circular saw when at its proper temper should be a pale blue colour, which colour is removed in the grinding.—A. R.

**Bird Stuffing and Mounting.** — POLYITE JOINER.—There is a book edited by L. Upcott Gill treating fully with the art of Taxidermy. It is published by the *Bazaar Exchange and Mart*, Strand, price 7s. 6d. Ward & Co. also publish a book on bird preserving, price 1s.; this treats of skinning the birds, and is a very good book for a young beginner. With this book, and a few hours spent in the Natural History Museum, anyone could make a very good start. Waterton, in his "Wanderings in South America," published by Macmillan & Co., price 6d, gives full instructions for skinning and preserving birds for cabinets. Artificial eyes can be procured at Gardner's, 29, Oxford Street, London. As a preserving solution, corrosive sublimate can be made with eighteen grains of perchloride of mercury to ten ounces of water.—F. H.

**Castings.** — A CONSTANT READER. — Castings cannot be got up "nice and smooth" by the use of chemicals—that is, not to obviate the necessity for turning and filing. They can only be cleaned from adherent sand and scale. In the case of brass, this is done by immersion in dilute nitric acid—say, one of acid to eight or ten of water. An hour's immersion will suffice, after which they will be removed, washed in water, and dried in sawdust.—J.

**Tool Fitting.**—ARSENAL.—You can apply at the War Office, Pall Mall. But why not call at the Arsenal, and ask for foremen of departments? Little notice is taken of letters.—J.

**Tempering, etc.**—A. R. (*Blairgowrie*).—(1) Malleable cast iron *can* be welded by the same methods as wrought iron, but the joint is never safe, nor strong. As far as practical science is concerned, therefore, it is unweldable. (2) Welding cast steel is one of those jobs that every smith cannot tackle. The art consists in getting the precise temperature, which varies with steel of different qualities. *It should always be the lowest temperature at which it is possible to make the weld.* You must clean the surfaces as with wrought iron, but sand alone will not do for the flux, as is the case with iron. You must either use sand and burnt borax, or ground glass. (3) Temper drills, to bore hard substances, by plunging them into a block of *lead*, instead of into water or oil. Use paraffin to lubricate the drill.—J.

**Incubator Regulator.**—B. N. (*North Seaton*).—Look at the illustration carefully, and you will see that the well is open to the atmosphere. A little heat, of course, passes off, but no air, because it is sealed by the water which it moves up and down. The arm working on a hinge has nothing to do with the interior, and is fixed on the wooden top of the incubator.—C. M. W.

**Couches.**—LEMUR. — Couches like your sketch are generally made of walnut or oak, the framing part of beech, ash, or birch. Nearly all the wood that is seen is worked by the wood-turner and carver. Sizes of ordinary couch are about as follows, it being understood that there is no hard and fast rule as regards size. Length of couch on frame (not allowing for scroll projecting), 5 ft. by 2 in.; width, 2 ft.; height from floor to top of seat-frame, 11½ in. or 12 in.; height to the top of scroll from floor, 2 ft. 3 in.; height of back from floor, 23 in.; back about 9 in. shorter than seat. It should be framed up of 3 in. by 2 in. stuff, the rails tenoned into the legs; the round or elliptic end is sawn out in two pieces and dowelled together; the rails should be tenoned in the whole breadth at this end, and the legs allowed to stand up 1 in. for strength, the round end to be dowelled to the legs. The rails should all be kept back from the front of the legs ⅜ of an inch, to admit of the facing being put on, so that when it is on all will be about flush or level. On the front the scrolls are dowelled into the rails, and flush with them. These are made of 1½ in. stuff, same shape as the finished scroll. The carved scroll is then glued on in such a position that it forms a rebate on the inside edge, to allow for the stuffing, and a little over the other edge for the same purpose. The legs are turned out of 4½ in. stuff, and the squares cut down all round to make the turning project boldly. Two ¾ in. iron rods are put across the frame to give strength and hold against the pull of the webbing which goes across the frame for the stuffing; these are fixed in the following way: Holes are bored to receive the rods in the inside of the rails about ¾ in. deep; the length of rod is calculated for, and the rods are put in at the same time as the frame is glued up. The carved and turned pillar at the end of the back is out of about 3 in. stuff, and tenoned into the seat rail, and the rails which carry the spindles are the same width as pillar, and about 1 in. thick moulded on the edges to match the bottom moulding. A piece of 1 in. beech is glued on to the top side of the top spindle rail about ⅜ narrower on each side—this will form a rebate for the stuffing. These are dowelled into the pillar and into the scroll at the other end. The spindles go in with a pin at each end; the middle panel is dowelled in; all sharp edges should be taken off with a rasp to prevent cutting the stuffing materials. In cramping on the round end, it will be found of great service to cut a notch in the rails and in the shaped piece in order to get the cramp on to pull by. These pieces should be glued in again, and a bit of canvas glued over them.—H. H.

**Inlay Wood.**—OLD READER.—There are many kinds of wood used for inlaid centres of various articles of furniture. Amboyna is a yellowish wood of variegated shades, much used for inlaying. Satin wood also comes under the same head.—J. S.

**Binding.**—TYRO.—It is quite necessary to take out the old sewing in books to be rebound, and if you follow the instructions given in the articles you will be right. If you proceed in a proper manner, cutting the threads in the centre of each section, you will not damage your book. But if you rug and drive without cutting the threads, you will undoubtedly have torn leaves.—G. C.

**Castings.**—R. C. M. (*Bristol*).—Watch "Shop" for the answer to the above.

**Dulcimer Making.**—R. C. (*Tipton*).—You will find the article on "Dulcimer Making," in No. 31 of WORK, contains instructions for commencing to build that instrument.

**Removing French Polish.**—G. S. L. (*Hampstead*).—For flat surfaces, nothing better can be used than the steel scrapers as used by cabinet makers; for turned work use methylated spirits, though it can be nearly all got off by the application of strong hot soda water, to which has been added some oxalic acid; or, if a large quantity is required, use the following: ½ lb. American potash, ½ lb. soft soap, ½ lb. rock ammonia, 1 lb. washing soda, threepenny-worth of nitric acid, 1 gallon of water. Apply with a fibre or scrubbing brush, taking care of the hands. Swill off with plenty of clean water. When dry, oil and fill in; then repolish with clear polish to show up the natural grain.—LIFEBOAT.

**Fretwork Patterns.**—E. J. C. (*Kennington Park, S.E.*).—I advise you to search through Indexes to Vols. I. and II., not only to alight upon the information you are at present in search of, but also to gather several useful paragraphs relative to fretwork. Search the "Shop" columns more particularly for handy wrinkles.—J. S.

**Battery Plates.**—R. E. A. (*Portsea*). —The battery plates may be of any thickness from ¼ in. upward. The carbon plates may be ⅜ in. or ½ in. in thickness without any disadvantage other than taking up more solution space for the thicker plates. Very thin zinc plates are soon cut through by the acid, and very thin carbon plates are liable to breakage. Rolled zinc plates are preferable to those of cast zinc. The thickness of the plates did not interfere with the light from the lamp. The lamp did not light because either it alone, or its resistance, together with that of the connections, was too high for the current generated in the battery. The lamp must have a resistance not exceeding 8 ohms.—G. E. B.

**Repairing Incandescent Lamp.**—W. E. B. (*Birmingham*). —If the platinum loops are not broken off into the glass, you may make connection with them by soldering a scrap of No. 20 copper wire to each. You may even get at enough of the platinum wire to make a joint with the copper by carefully filing away a little of the glass around the end of the wire. Smoothly flatten one end of the copper wire to thin foil, and make of this a socket to fit the end of the platinum wire; then dip it in soldering fluid, and apply a bead of solder on the tip of a soldering iron.—G. E. B.

**Aquarium and Aviary.**—NOVICE. —The mahogany pillars you speak of would, in my humble opinion, be quite unsuitable for the purposes of your sketch. An article on a Wardian Case is in the hands of the Editor, and when published will give you sufficient instruction, with a little modification, to carry out your ideas.—C. M. W.

**Fountain.** — A READER. — A fountain worked by an electric motor can be obtained from The Maughan Patent Geyser Company, Queen Victoria Street, E.C. I believe it is a patented article, but I am not so sure of its efficiency. A description of a single self-acting fountain was given in WORK last year; this without ornamentation would suit your purpose. A great many readers of WORK have made this fountain successfully.—C. M. W.

**Amber Mouthpieces for Pipes.**—CONTRIBUTOR.—Amber mouthpieces can only be obtained at first cost from Austria, where the trade is chiefly in the hands of Jews, and is the speciality of a very limited area; no British house could compete with these makers. CONTRIBUTOR should consult a London directory for an importer's address. If he has access to the current and last volumes of a London periodical of limited circulation called *Tobacco*, he may there find information about the trade in question. Cut amber is costly; compressed or "moulded" amber less so, but how it is moulded is, we believe, kept a trade secret. The mouth-

pieces and trinkets made of it have, however, every property of amber, even to the electric one. "Parkesine" (an imitation of amber) was the invention of a Birmingham man. It has not been largely taken up in this country, but has found more favour with the French. Another imitation, now being manufactured in the United States, is "Silleroid." This latter has the disadvantage of being so inflammable as to be almost explosive.—S. W.

**Thermograph.**—J. F. (*San Remo*).—J. F. has designed a thermograph on the following plan. A spirit thermometer is delicately balanced like the beam of a scale; it contains also a short column of mercury, which the expanding and contracting spirit displaces—by so doing shifting the centre of gravity, so that it oscillates. One end carries a style. In front of the style is a cylinder which revolves once in seven days. It is intended to make the style record by a curved line the varying temperature. At this point he is confronted by a difficulty. If the style is replaced by a pen, there will be introduced, by the constant loss of weight, an error; also there will be friction and other evils which he points out. His hope has been that, by electricity and a chemically-prepared paper, he might be able to produce what he desired. He has tried potassium iodide, but without success. Now, the fact is, that a variety of chemicals are acted upon by electricity, but, unfortunately, J. F. hars the way by one condition, which is fatal, as far as I know, to success—that is, the paper must be *dry*. In all the processes known to me, moisture is necessary for chemical reaction. I have stated this much, as some correspondent may be able to suggest a method that I have not tried. There is a plan, however, which, I think, will be better even than a chemically-prepared paper, and which will in no way detract from the elegance of the instrument (a sketch of which is supplied me). It is to employ a small induction coil. Let one terminal of the secondary be connected with the metal pillar carrying the balanced thermometer; from the central pivot on which it turns, carry a small rod or wire which shall have metallic connection with the metal style. The other end of the secondary wire must be connected to the metal drum carrying the ruled paper, which should be a fine, smooth paper like "foreign post." As the current flows a series of small holes will be punctured in the paper, which on being removed may be used with an ink-pad, like one of the letter multiplying methods in use. This is the most perfect plan that I can suggest; by it there is no change of weight to shift the point of gravity; nothing to produce friction. J. F. asks for an opinion on his design, and says his critic need not be afraid of hurting his feelings. So far from passing an adverse criticism on his instrument, I think it a capital idea, and with the addition I have suggested, I believe it will make a most efficient electro-thermograph.—O. B.

**Charge for Battery.**—J. H. (*Manchester*).—Without seeing the battery, and in the absence of its description, one cannot well tell you how to charge it "completely." So many different batteries are, and have been, used for gas-lighting apparatus as to render a reply to your question a mere guess. If the gas-lighter is a small cylinder with a long rod projecting from it, there may, or may not, be a battery. It may be worked by a small machine. Tell me how the battery is made, and I will tell you how to charge it.—G. E. B.

**Electrotyping.**—H. G. W. (*Bath*).—The best book I know of on the subject is Watt's "Electro-Deposition," third edition, price 9s.; Mr. McMillan's "Treatise on Electro-Metallurgy," price 10s. 6d., is also a good book on the subject. A cheaper manual is Urquhart's "Electrotyping," price 5s.—G. E. B.

**Insulation for Coil.**—H. G. W. (*Bath*).—If you suspect the coil to be imperfectly insulated, immerse the whole instrument in melted paraffin wax, and keep it there until bubbles have ceased to come off from the wire. Running the wire through the hot wax, and basting each layer with it as the wire is wound on, will also improve the insulation. The efficiency of the coil will depend largely on the perfection of the insulation.—G. E. B.

**Coil for Vacuum Tubes.**—W. H. (*Pollockshaws*).—A wooden bobbin measuring 4½ in. by 1 in., with a body 1½ in. in diameter, having a ¼ in. hole in it, is altogether unsuitable for the purpose of forming part of either a shocking coil or one to illuminate vacuum tubes. The ends of this bobbin may be sawn off, and bored to fit the tube of a coil, but a wooden tube would be altogether unsuitable. Make a tube of $\frac{1}{16}$ in. sheet ebonite, 4½ in. to 5 in. in length, and ⅞ in. in diameter. Turn holes in the bobbin ends to fit this tube, and glue the ends of the tube into these. The tube may be made of strong thin paper, glued, and wrapped around a glass rod to the required thickness. When this is dry and hard, it may be slipped off from the rod and glued into the bobbin ends. The core, made of a bundle of No. 20 soft iron wires, will fit into this tube. Over the tube wind two layers of *silk-covered* No. 18 copper wire. Cotton-covered wire is not nearly so good. Over this primary coil of wire wrap two or three layers of tough thin paper, soaked in melted paraffin wax. See that the paper has no holes in it, and baste it well with the hot wax on the outside. *Fill up* the bobbin with No. 36 silk-covered copper wire, coated with hot paraffin wax, and wound on evenly throughout. If you use No. 32 you will not get such a long spark as that from No. 36. This coil may be worked with current from three or four pint bichromate cells, and will give a smarter shock than you will care to take across the hand whilst spanning the terminals of the secondary. If you care to use your No. 18 cotton-covered wire for the primary, and your No. 32 silk-covered wire for the secondary, you will only get a very mild shocking coil, but it will be useless for lighting up vacuum tubes.—G. E. B.

**Bent Iron.**—R. N. (*Grays*).—If you are anxious to commence, you may get some good designs and much information on the subject by joining the Home Arts and Industries Association, Royal Albert Hall, S.W. The annual subscription is very low. You may get materials of Clark and Hunt, 160, Shoreditch; they promised me some time ago they would keep it in stock. The tools required are few and inexpensive.—WORKER BEE.

**Re-painting, etc., Blinds.**—R. J. (*South Devon*).—The ordinary charge for re-painting, new tapes and cords, and re-fixing Venetian blinds is, in London, 4d. per foot superficial, but it should be worth more to paint the iron corrugated laths mentioned. R. J. has five large blinds, which at 4d. per foot would cost £3 1s. 2d. I should say the value of the work on iron laths would be at least 25 per cent. extra—£3 16s.—B. A. B.

**Stencils and Brushes.**—A BEGINNER.—A short paper on cutting stencils appeared in WORK, Vol. I. The best way of cutting is upon a piece of old plate-glass, flat upon table or bench. Use a sharp-pointed pocket-knife, and keep an oilstone handy to "ruh up" edge of knife every few cuts. Next to the foregoing, the main thing required is practice. With reference to the "dahbing" or "hrushing on" motions with stencil brush (Fig. 1), the former is most correct for all stencil work, and is the safest. In some cases the pattern will not look regular and one even tone if brushed on. Rubbing is often quickest for stencilling on a distempered ceiling-flat,

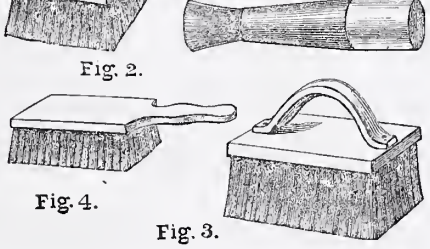

Fig. 1.

Fig. 2.

Fig. 4.

Fig. 3.

Stencils and Brushes.

and where we use thin distemper or flat paint, which is more of a stain than body; but care is always necessary to get clean work with brushing. Respecting stipplers and their use, I give you a cut of three herewith, Fig. 2 having reversible handle, and Fig. 3 bridge handle. They are used for distributing paint or vehicles in a perfectly regular manner, and for taking out paint-brush streaks. In use, the paint is first spread—a good coat—and then the work is at once stippled with the ends of bristles until a regular surface of a granular nature is obtained. See articles on "Plain and Decorative House Painting," Vol. I.—LONDON DECORATOR.

**Plant-Forcing Case.**—SOMERSET.—Full instructions for making a plant case warmed by artificial heat will be given in a future number of WORK, together with an efficient heat regulator.—C. M. W.

**Water Spray.**—WEEKLY READER.—In order to throw a spray of about 30 ft. of water from the tub in your garden you will need a strong force pump—a suction pump might readily be made in tin work—but I would not advise you to attempt a force pump unless you can work up solid metals; the better plan would be to use a long length of hose as a syphon direct into your cistern, and thus conduct the water to the points required; in a smaller spray, certainly, but quite as convenient.—C. M. W.

**Incubator.**—F. W. A. (*Peckham*).—If the water in your incubator is nearly boiling, you should have no difficulty in getting up the required heat in the egg drawer; there should be no brown paper in the bottom of tank; and the temperature should be taken at the line corresponding to *the top* of the eggs. If the temperature at this point is high enough you need not trouble about the heat an inch or two lower down.—C. M. W.

**Split in Violin.**—R. T. (*Galashiels*).—Carefully remove the belly with a knife which is not very sharp, lay it on a flat piece of board, and drive small tacks all round close to the edge of the belly; this done, take out a sufficient number of the tacks on one side to release the belly. The joint should then be sponged quite clean, and laid aside to dry. The edges should be covered with fresh glue, the belly replaced in its position on the board, and the tacks again driven in; then draw tightly across, from one tack to another, a piece of strong twine; you will thus be able to get the joint quite close.—B.

**Cast of the Foot.**—CRISPIN.—The mould, as well as the cast itself, will have to be made of plaster, and not, as Crispin supposes, of clay. He should invest twopence in Nos. 74 and 81 of WORK. In 74 (Vol. II., p. 349) he will find all about plaster and the way of using it; and in 81 (Vol. II., p. 578) are special directions for casting parts of the living human body. The way in which a foot may best be cast is there illustrated by a diagram.—M. M.

**Cost of Electric Bells.**—GLENIFFER.—The relative cost of fitting a six-roomed villa with electric bells, as compared with the old system of pull-bells, will depend upon the number of bells you may require. If you do not employ an indicator, you will have to put a bell to each room, and this will increase the cost. The total cost will be from £4 15s. to £5 for material. In a new house provision should be made for laying the wires in zinc tubing laid in the plaster. Best quality line wires are coated with rubber under the cotton, to resist the damp.—G. E. B.

**Gramme Dynamo.**—G. W. (*Bradford*).—It is not an unusual occurrence to find an amateur in trouble with a dynamo of his own construction. Some little point in detail is missed, and this ensures entire failure in the performance of the machine. It may be a slight fault in the insulation of the wires; a fault in winding or connecting the coils; a fault on or in the commutator; a wrong adjustment of the brushes, which are given too great or too little bend; or the machine is driven in the wrong direction. Probably either one or more of these faults exist in your machine. First, test the insulation of the wire by means of a battery and galvanometer. If this is all right, examine the connections—one may be loose. If these are right, try to run the machine as an electro-motor, with current from your other dynamo, adjusting the brushes until you get the machine to move at its best. It must now be run as a dynamo, in the opposite direction to that of its movement as a motor, and the brushes must be adjusted to meet the requirements of a dynamo.—G. E. B.

**Roofs.**—D. LE D. (*Ireland*).—In answer to your query as to whether shingle roofs are suitable for this country (Ireland), I should say no, bearing in mind that Ireland is always considered to have a humid atmosphere. I have never met with a case where they have been specified for new work, and the only experience I have had with them has been in repairing old roofs; and this, I think, you will find to be the general modern experience. The fact of their not being used much in modern building tends to show that they have not been found as good as other and cheaper methods of covering a roof. They are fixed in the same manner as slates or plain tiles, and are mostly made of oak.—E. D.

**Patterns.**—J. C. B. (*Great Ayton*).—I do not know of any other fire-proof solution. Nothing of the kind is used by founders. The patterns are simply varnished or painted, and put away in rooms removed from the workshops. As a rule, no fire is allowed in a pattern stores, and no naked candle, only lamps enclosed in lanterns.—J.

**Spring.**—T. B. (*Harwich*).—You go to work the right way, but perhaps the section at the bend is less than that in other parts, and this, together with the hole there, becomes a source of weakness. Then you must sacrifice some amount of elasticity to retain strength.—J.

**Paint for Cart.**—J. C. (*Belfast*).—To get a good and durable bright red for the wheels of your cart, it would be advisable (after well cleaning and preparing them) to paint them once with Venetian red pigment, and then finish with two coats of vermilion. In both cases it is best for such work, and where only small surfaces have to be covered, to mix the pigment with one-third japanners' gold size and two-thirds of turpentine until of working consistency. The Venetian red is sold ground in oil, and the vermilion in powder only. Strain the paint before using, and finish with two coats of pale carriage varnish. You will then get a durable job.—F. P.

**Bicycle Steel Castings.**—B. C. (*Nottingham*).—Malleable steel castings can be had of Forsythe and Millar, Broad Street, Bridgeton, Glasgow. Crucible steel castings of the St. George's Cycle Co., 293, Hampstead Road, London. Steel castings of Brown Brothers, 7, Great Eastern Street, London. Brown Brothers will send their catalogue, which has innumerable illustrations of steel stampings for cycles, both diamond and cross-frame safeties. These are quite good enough for the highest class machines.—A. S. P.

**Enamel Tricycle.**—J. C. (*Bedale*).—Any enamelling done at home must be put on with a brush, like paint. The tricycle should be well cleaned and smoothed down with emery-cloth or glass-paper. The process of applying the enamel should be done in a warm room, and the parts may be heated at the fire, when the enamel will flow more freely. Use the Club Hard-drying Black Enamel, and as it dries very quickly, put it on with a brush an inch broad, covering as much as possible with a brushful, and take care not to go over the same place twice. The above enamel can be had in 1s. bottles at any of the cycle shops. The above is the only method, except stoving or baking, and J. C. would have to send the machine to an enameller or provide a stoving plant, costing about £12.—A. S. P.

**Broken Fork.**—J. W. R. (*Westminster*).—Unless J. W. R. is a mechanic and acquainted with brazing, he had better give his machine into the hands of a repairer. If the fork is broken up at the crown, a new fork has got to be fitted the same curve and size as the other. It has got to be brazed on. If broken anywhere else in the length, it may be mended by fitting about three inches of a smaller-sized fork inside the broken one, the broken part being in the middle of the three-inch piece; the parts must be

well filed and fitted clean for brazing. A practical brazier could do this easily enough, but the job at home by a green hand would be a failure.—A. S. P.

**Advice on Emigration.**—D. A. T. (*No Address*).—You may do well in either Queensland or South Africa. The latter is more unsettled, and probably more rough, but wages are higher as a rule, and so are the expenses of living. I believe New Zealand has even a grander future than Australia in the near future; the conditions of existence will be easier. Do not wait for a job at your trade as wheelwright, but take the first that comes to hand that you can do, and look about you until you see an opportunity to work at your trade. Neither loaf about the towns longer than obliged, but get back into the country, and settle down in a good position on a main road; you may then soon get a little business of your own around you, which will increase in proportion to the rate at which people settle down in the district. For myself, I think I would prefer N.W. Canada, 150 or 200 miles N.W. of Winnipeg.—WORKER BEE.

**French Clock Snail.**—RICHARD III.—Before altering the snail of the clock, make sure the fault is there. See that your rack teeth are all straight, that none are longer than the others, and that none are thicker on the tops; next see that the pallet gathers up only one tooth at a time, then see that the rack arms are not loose; if this is all right, try round, and note which hours are wrong, and see if the rack falls too far or not far enough: if not enough, scrape or file the snail where the rack drops till it drops right; if it drops too far, take off the snail from hour wheel, or jumper wheel, and swell it out by hammering with a round-faced hammer, or you might stretch the point of the rack that rests on the snail till it drops fair at the hours where it used to be wrong. Then try round, and file the snail down at the hours where it does not drop sufficient. To make a new snail, mount a round piece of brass on your hour wheel, and put a pointed pin in the rack arm in place of the half-round or square one. Put the rack hook in the first tooth of rack, and hold tight with one hand while you turn the hour wheel, or jumper wheel, round, letting the pointed pin of rack rest on the piece of brass for new snail; now put rack hook in second tooth, and so on till you have the twelve circles on the new snail that is to be. Next put on the minute wheel, shake minute and hour wheel (if snail is on it), put on your minute hand, and see that the striking is let off at the twelve; turn the hand down to six, and hold it there tight while you let the rack drop the whole twelve teeth with the pin resting on the snail; press on it so as to leave a clear mark. Now turn the minute hand round an hour, and repeat the scratch till you have twelve radial lines, as well as twelve circles, on the snail (of course, if the snail is on a jumper wheel, you simply move one tooth of it and make your scratches). All you have to do now is to file out between two radial lines down to the first circle, take the next radial line and file down to the second circle, and so on till you have the twelve steps, then file the pin in rack tail half through, and your snail is done.—A. B. C.

**Cleaning Telescope.**—SCENERY.—There is no mystery in the matter. You may take the telescope to pieces and clean it. Use a soft cloth or chamois leather for the lenses, so as not to scratch the surface of the glass. The risk is lest, knowing nothing of the matter, you might fail to replace the lenses in their proper cells. To entirely avoid accident, you had better remove only one piece of tubing at one time, and clean only one lens at one time, replacing the lens exactly as you found it before you touch another.—E. A. F.

**Diapason.**—BRIXTON.—The pins for the long keys should be inserted near the centre; about five-ninths of the length of the key, measured from the front, would be about the usual position. The pins for the black keys should be about ⅝ in. behind those of the white keys. Any weighting that may be requisite can best be determined when the action is completely attached. As regards the length of the keys, that will be a question for you to determine, having regard to the position of your action. Any length that will work conveniently will suffice.—M. W.

**Grained Arches.** — M. W. (*Manchester*). — "Masonry and Stonecutting," by E. Dobson, price 2s. 6d., is as suitable a book as you can have; it is published by Crosby Lockwood & Co., but you can order it through any bookseller. There is an atlas of plates to it, which I think is included in the price named, but you must inquire about this. After procuring the book, if you examine any work in progress or completed, you will get a much better idea. There is also "Masonry and Stonecutting," by P. Nicholson, published at 28s., which I believe you might get second-hand from Batsford, 52, High Holborn, London, for perhaps 10s.; this is a larger book.—M.

**Colour Mixing.**—J. G. P. (*Crewe*).—First obtain a knowledge of the names of pigments, which you will find are not always synonymous with the colours. Dutch pink is yellow, verditer is blue, lake is not purple-blue always, but sometimes green, yellow, brown, etc., or you will find it as a pigment colour, with a chalk base, or body, for fugitive colours. Doubtless a colourman's catalogue will help you at first better than a learned treatise: as Heywood & Wilkinson, Battle Bridge, N., or Mr. Parsons, Long Acre, W. C. For books: "Painting and Painters' Materials," by C. L. Condit, E. and F. N. Spon, Charing Cross, London; or, "Artists' Manual of Pigments," by Standage, Crosby Lockwood & Co., Stationers' Hall Court. This last is a low-priced book, the first a costly one.—J. C. K.

**Camera.**—T. J. (*Sheffield*).—To give practical details for the construction of the apparatus you require would occupy too much space for these columns. It would be the better plan to borrow one of the pattern you most fancy, and copy it. Some scores of different kinds are now in the market, of varying degrees of effectiveness. The most simple are, as a rule, to be preferred, and less likely to get out of order. For smooth working and real effectiveness a quarter-plate, or 5 × 4 camera, enclosed in a case and with a good supply of light double dark slides, is as good as any. The back of this can be made to open and allow focussing, and the exposure made by a lever on the outside connected with an instantaneous shutter. The lens is a very important item, and should not be less than six inches in focus. Work with a large aperture, and give good depth of definition. The focussing, as well as the finder, must be arranged and worked from the outside of the case.—D.

**Tables of Weights.**—IRONMONGER.—Almost all engineers' "Pocket Books" contain these tables, so you have a wide choice. There is a book of "Engineers' Tables," price 1s., published by Messrs. E. and F. N. Spon, Strand, W.C., London, which might suit you. These weights are very easy to calculate, for a bar of iron 1 in. square and 1 yd. long weighs 10 lbs., and steel is 2 per cent. heavier.—F. C.

**Blowpipe.**—ROMEO.—Hydrogen can be burnt at the end of a brass tube, but this tube should not have any openings in it on the side, as in a Bunsen burner. You would have to make a large quantity of the gas, store it in a gas-bag or reservoir of some kind, and conduct it thence to the burner. I presume that you would make it by adding sulphuric or hydrochloric acid to zinc or iron, and the gas would not come off steadily enough or in sufficient volume to burn in the burner straight off. This flame would be hot enough to melt thick glass tubes, and thus there would be no need to make an oxy-hydrogen blowpipe. Your want of coal-gas prevents you making the hydrogen in a cheaper way; and considering the large amount of materials required to make sufficient gas, I think it will be cheaper for you to save up till you get the 6s. 6d., and then buy a French blast spirit-lamp, which I have found to work capitally. Hydrogen is explosive if any air be mixed with it; so collect a little in a test-tube, and, by applying a match to this, see that it is free from admixed air before conducting the gas to the reservoir.—F. B. C.

## III.—QUESTIONS SUBMITTED TO CORRESPONDENTS.

**Pompeian Blue.**—CYANOS will be obliged to any reader who will give him the receipe for making the old Pompeian blue colour.

**Band-Sawing Machine.**—BON ACCORD writes:—"Will some practical reader kindly give me sketch and particulars of a Band-Sawing Machine, and how to construct it, with a wooden frame, to be used mostly for wheel work, to be driven by power?"

**Blast Gas Furnace.** — A. B. (*Manchester*) writes:—"I shall feel obliged for any information as to make and price of Griffin's Patent Blast Gas Furnace."

**Fretworker's Address.**—F. G. B. (*Hull*) writes:—"Will anyone kindly tell me the address of Russell, designer of fretwork?"

**"Desideratum" Fountain.**—AMATEUR writes:—"Can any reader of WORK give particulars of a self-acting fountain called the 'Desideratum,' with sketch of same? also instructions for making it?"

## IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

**Ferrules for Fishing-Rods.**—P. T. (*Kasan, Russia*) writes, in reply to TELESCOPIC (see page 812, Vol. II.):—"You can get ferrules for fishing-rods of any size, and in any quantity, from Messrs. S. Allcock & Co., Standard Works, Redditch. I suppose any other firm in the wholesale fishing-tackle trade can supply them, but I give the name of Messrs. Allcock & Co. because I *know* that they make the article wanted."

**Plane Iron.**—R. H. W. (*Lewisham*) writes, in answer to query from ONE IN DISTRESS (see page 522, Vol. II.):—"You might try the iron illustrated in *Carpenter and Builder* of June 27th; it has three broad grooves in it, and the inventor claims that it does not want grinding. This, if it is a practical invention, would be the cheaper; or a more expensive alternative, the machine sold by Melhuish or by Moseley for sharpening plane irons after the principle of a grindstone, with a stone that puts a finishing edge to the iron. It is turned with one hand, and has a rest affixed, which keeps the iron at the right angle for sharpening."

## V.—BRIEF ACKNOWLEDGMENTS.

Questions have been received from the following correspondents, and answers only await space in SHOP, upon which there is great pressure:—CHICK; G. C. (*Hackney*); E. F. B. (*Liverpool*); H. B. (*Notts*); TURNER; H. N. (*Ipswich*); F. H. (*Streatham Hill*); E. E. S. (*Devon*); F. L. (*West Cowes*); IMPATIENT; A. R. (*Scorrier Saw Mills*); INCLINED PLANE; SEWING MACHINE; C. T. B. (*Chapel-en-le-frith*); T. F. (*Aberdeen*); PATENT BALL BEARING CASTOR CO. (*Leicester*); J. F. (*Boston*); P. H. (*Camberwell, S.E.*); W. C. G. (*South Norwood, S.E.*); E. M. C. (*New Humberstone*); G. A. B. (*Yorks*); B. MCC. (*Kilmarnock*); T. T. (*Harlesden, N.W.*); PUZZLE; G. E. B. (*Lewisham*); G. P. (*Fulham*); TABLETOP; J. M. (*Kilmarnock*); A. T. (*East Greenwich, S.E.*); J. T. B. (*Warrington*); F. D. B. (*Stamford Hill*); E. E. D. C. (*Crewe*); A. M. (*Glasgow*); E. D. R. (*Staffordshire*); H. O. H. (*Bristol*); H. R. J. (*Canning Town*); T. J. S. (*Tottenham*); R. L. (*North Wales*); SUBSCRIBER; C. T. (*Boston*).

# FRETWORK FOR AMATEURS OF BOTH SEXES AND ALL AGES.

Eclipse Design. No. 102.

Wall Bracket. Price 6d.

## THE MOST PROFITABLE AND FASCINATING OF ALL HOME PASTIMES. EASILY LEARNT.

J. H. SKINNER & Co. having *Dissolved Partnership*, are offering their *Enormous Stock*, including 250,000 FRETWORK PATTERNS and 100,000 ft. of Solid and Three-Ply FRETWOOD, Veneers, &c.; 1,000 Gross of FRETSAWS, besides an immense quantity of TOOLS, OUTFITS, &c., as a special inducement to their customers to order at once.

**4,500 1s. Books of Fretwork Patterns**, each containing Twelve Large Sheets, beautifully lithographed, none of which would be sold retail at less than 2d., and many at 3d. and 4d. each; also

**1,200 2s. 6d. Books of Fretwork Patterns**, containing Twenty Sheets, 19 in. × 12 in., of new designs, many of which would retail at 6d. each. These Books,

**£375 in Value, will be GIVEN AWAY.**

Amateur customers ordering 5s. worth of designs from Catalogue will be presented with one of the above 1s. Books. Those ordering 10s. worth will receive a 2s. 6d. Book.

**An Allowance of 10 per Cent.** *in goods* will be made on all mixed orders for Wood, small Tools, Saw Blades, and Designs, amounting to 10s., and **15 per Cent.** on orders amounting to 20s. and upwards. NOTE.—*This reduction does not apply to Treadle Machines.*

N.B.—A SPLENDID OPPORTUNITY FOR BEGINNERS.

**Complete Fretwork Outfit**, comprising 12-inch Steel Frame, Forty-eight Saws, Awl, File, Four Designs (with sufficient Planed Wood and 1s. Handbook on Fretwork). **An Archimedian Drill**, with brass handle and Three Bits, will be **SENT GRATIS** with each Set. Post free for 3s. 6d. Outfits on Card, 1s. 6d. and 2s. 9d., post free. 6 ft. 2nd quality assorted planed Fretwood, 1s. 9d.; post free, 2s. 0d. 12 ft. ditto, ditto, 3s.; post free, 4s. 3d.

**SKATES!!!**—EVERY PAIR WARRANTED.—Sizes, 7½ in. to 12 in. No. 1, Unpolished Beech, 10d. per pair. No. 2, Polished Beech. 1s. 6d. per pair. No. 5, "Acme" pattern, all steel, 3s. per pair. No. 7A, "Caledonia" pattern, self-adjusting, one screw fastening the whole skate, the best principle, 6s. per pair. No. 8, Metal frame, with strap complete, 1s. 9d. per pair; postage, 5d. per pair. These are not rubbish; we warrant every pair.

The first dose will give relief in twenty minutes. Every sufferer is earnestly invited to try one Box of these Pills, and they will be acknowledged to be

## WORTH A GUINEA A BOX.

For Females of all ages these Pills are invaluable, as a few doses of them carry off all humours, and bring about all that is required. No female should be without them. There is no medicine to be found equal to Beecham's Pills for removing any obstruction or irregularity of the system. If taken according to the directions given with each box, they will soon restore females of all ages to sound and robust health. This has been proved by thousands who have tried them, and found the benefits which are ensured by their use.

For a Weak Stomach, Impaired Digestion, and all Disorders of the Liver, they act like magic, and a few doses will be found to work wonders on the most important organs in the human machine. They strengthen the whole muscular system, restore the long-lost complexion, bring back the keen edge of appetite, and arouse into action with the rosebud of health the whole physical energy of the human frame. These are FACTS testified continually by members of all classes of society, and one of the best guarantees to the Nervous and Debilitated is, BEECHAM'S PILLS *have the largest Sale of any Patent Medicine in the World.*

## Beecham's Magic Cough Pills.

As a Remedy for Coughs in general, Asthma, Bronchial Affections, Hoarseness, Shortness of Breath, Tightness and Oppression of the Chest, Wheezing, &c., these Pills stand unrivalled. They are the best ever offered to the public, and will speedily remove that sense of oppression and difficulty of breathing which nightly deprive the patient of rest. Let any person give BEECHAM'S COUGH PILLS a trial, and the most violent Cough will in a short time be removed.

Prepared only, and sold Wholesale and Retail, by the Proprietor, THOMAS BEECHAM, ST. HELEN'S, LANCASHIRE, in Boxes, 9½d., 1s. 1½d., and 2s. 9d. each.

Sold by all Druggists and Patent Medicine Dealers everywhere. *N.B.—Full Directions are given with each Box.*

**A Suggestion for a Rustic Verandah—Front Elevation.**

### SUGGESTION FOR A RUSTIC VERANDAH.

BY ARTHUR YORKE.

GENERAL ARRANGEMENT AND MATERIALS—CONSTRUCTION OF FRONT—ROOFING—LINING OF ROOF.

*General Arrangement and Materials.*—The above elevation of a rustic verandah I have called a "suggestion" merely, for to arrange any definite plan, or to fix accurate dimensions, for an appendage of this kind demands some previous knowledge of the building to which it is to be attached. All that I can do, therefore, is to give a design that shall be easy of adaptation, and this, I believe, will easily be adapted to many houses of modest size.

The illustration is, I should observe, a front elevation, drawn to a scale of ½ in. to the foot. It is shown as a part only which may be extended to any required length at either end. As to the width, that indicated is 3½ ft. from the wall to the middle of the collar-posts, the eaves having a further projection of 6 in. For a cottage verandah the width given is a satisfactory one. It gives sufficient room for seats on a hot day, or for a promenade on a wet one. The width, as also the height, can easily be increased to suit a larger house. The verandah is supposed to be built on a raised platform of brick or stone.

All those parts, even the minor ones, which can be considered as belonging to the framework, are of straight natural wood, and by choice of larch; whilst the mere filling-in of rustic open-work is of small crooked stuff—probably oak or apple tree. The roof, as drawn, is of tiles; but of this I shall have to speak more particularly further on.

*Construction of Front.*—It will be seen that the collar-posts which support the verandah are arranged in pairs, so that 3 in. or 3½ in. poles will suffice for them. Their bases are supposed to be dowelled to the

masonry of the platform on which they stand; they are 6 ft. 6 in. high. Except at the entrance or entrances, a sill of half-stuff runs from post to post on the platform. At a height of 3 ft. 3 in. they are connected by a round bar of smaller material, and, again, by a second cross-bar of similar size to the last, at 6 in. from their upper ends. On the tops of the posts rests a lintel of half-stuff of larger diameter—say 5 in. The upper and lower cross-bars come opposite to the middles of the posts, but need not be mortised into them, for if their ends are cut V-shaped, so as to clip the posts, they can be nailed quite firmly. The lower cross-rail is placed at a convenient height for leaning upon. At a height of 5 ft. 6 in. caps are formed by simply nailing four pieces of quartered stuff round each post. The diagonal braces which start from above the capitals will be observed to pass in front of the upper cross-bars, to which and to the lintel they are nailed. The illustration sufficiently shows how the panels between the pairs of posts and the frieze between the upper cross-bar and lintel are filled with open-work of small crooked branches, which contrasts in a pleasing manner with the straight pieces of the framework. This open-work may be made available for, and will be found useful as, a support for climbing plants.

*Roofing and Lining of Roof.*—In so narrow a structure the rafters alone will suffice to keep all in place, without anything of the nature of a tie-beam being called for. These rafters will be of half-stuff, and for the given width a length of 5 ft. will be enough; this will allow of such a projection beyond the lintel as will give the eaves a width of 6 in.; the pitch will be rather less than a true pitch, but amply steep for the purpose. A piece of half-stuff nailed to the wall will support the upper ends of the rafters.

In forming the roof it is proposed to board over the whole space upon the rafters, and to nail the tiles or other covering upon the boards. For the non-professional workman this is much easier as well as much safer than the use of laths. It will also facilitate giving a neat finish to the inside. It is suggested that the inside should be lined beneath the boarding with rush matting. This is an inexpensive material; its brownish-green hue is pleasing to the eye, and it is so inartificial in appearance as to harmonise well with the natural wood. After fixing the rafters the matting is to be stretched tightly across them before the boards are nailed down. It is probable that the rafters will be arranged with intervals of about a foot between them, and to hold the matting more closely to the boards a strip of split rod may be nailed up the middle of each space, or strips may be nailed so as to form a simple ornamental pattern; an intricate one will not be desirable, as fixing it will be overhead work.

A neat, but less characteristic, ceiling may be formed by, instead of using the matting, painting the boards of a suitable colour and slightly ornamenting them with split strips of rod. In this case the boards should be planed. None will be better for this purpose than $\frac{3}{4}$ in. flooring boards, and these are commonly sold steam-planed on one side. Other ways of lining the roofs of rustic buildings are discussed in my paper on Summer-Houses, Vol. II., pp. 65 and 197 (Nos. 57 and 65). To these articles the reader can refer, but it must be remembered that a lining suitable for a summer-house may not be sufficiently neat for a porch or verandah.

In the same papers something is also said with regard to roofing materials, thatch being more especially commended in point of taste. A thatched verandah, however, would scarcely be desirable unless attached to a thatched cottage. Practically the choice lies between shingles, metal, and tile or slate. Shingle roofs have been spoken of in the first of the two articles above cited. A metal roof is, undoubtedly, that most easily fixed by an amateur, and should metal be used in this case, I should, as a matter of appearance, rather recommend black sheet iron than galvanised, and to keep it painted; paint stands far better on the black than on the galvanised surface. As a matter of taste, metal looks thin and poor, but it becomes less objectionable when painted; a deep, dull red would be the colour to be preferred. Perhaps, of all available coverings, nothing will look better than tiles, as drawn. Red or buff tiles will in themselves look best, but the choice must, to an extent, be influenced by the general covering of the house. It may be, if that is of slate, that small slates will come in most appropriately; but whichever of these coverings is used, the best finish against the wall will be with a "flashing" of metal, as shown.

## FRENCH POLISHING—BODYING IN.

BY D. DENNING.

THE BODY—BODYING IN ON CHEAP FURNITURE—PREPARATION OF POLISH—HOW TO MAKE IT—WHITE POLISH—BROWN POLISH—REMARKS ON THE POLISH OF THE MANUFACTURERS.

If it can, without conveying the implication that some of the details of French polishing may be performed in a careless manner, be said that one operation is more important than another, the remark applies specially to the "bodying in," as it is technically called, of the work with the polish. In ordinary English, bodying, when applied to the polisher's craft, or rather art, simply means coating the wood with a thin layer of the polish, evenly and smoothly distributed. On the way this is done the appearance greatly, and the durability of the shine or gloss entirely, depend. If the body is thin, the polish—by which is meant the gloss subsequently given to the film—may be beautiful at first, but cannot last, as the polish—this time the material is referred to—sinks or perishes. On the other hand, if the body is too thick, though the gloss may be all right, the work will not look well. It is apt to be "treacly" looking, and give rise to ideas of varnish having been used, besides impairing the pure tone of some kinds of wood. Therefore, let the novice be careful about the way in which he does the bodying, if he wants to excel in his work. It may be well to remind novices, or those who are not accustomed to see good work—or, shall I say? the highest degree of excellence to which polishing is capable of being brought—that many specimens that are seen are anything but good. Only in the best shops or houses, and on the best pieces of cabinet work, can the finest polishing be seen. Polishing on second-rate—even if substantial and sound—furniture is generally on a par with the woodwork. The lower this is in the scale the worse the quality of polish; therefore the gaudy and shiny-looking cheap furniture, which unfortunately is too often seen in all but the very best shops, etc., must not be taken as models to be copied in polishing. To meet the public taste, the price paid for polishing has to be cut down, with the result that inferior polish and less time are spent on the work than would be were excellence the prime consideration. I do not say that even the best materials and the expenditure of even more than the necessary time or labour will ensure good work in unpractised hands; but they are, at any rate, important factors, and amateurs and novices will be wise not to use either inferior materials, or to be unduly discouraged if their efforts are not as successful as might be wished.

With these preliminary remarks—and I am afraid some of my younger readers may think them of comparative unimportance, though they are not so—we may proceed on our course.

*Polish.*—As the quality of materials has been referred to, a few hints on the polish and its preparation will not be uncalled for, especially as so many readers of WORK are continually asking questions on this subject for answer in "Shop." Those who want a good recipe for polish will find the following thoroughly reliable, and neither I nor anyone else can tell them of a better—no, not even if it has been "in print." There may be cheaper methods of making a given quantity of polish, and there may be many giving more ingredients, but none of them surpasses, or is equal to, the simple mixture of shellac and methylated spirit. If any reader tries it, and does not find his work satisfactory, he must blame something besides the polish, for the fault will not be in it. It is just possible that some novices may think that they could manage better with a polish containing, say, half a dozen different ingredients, all of them weighed out and measured with the utmost nicety. If so, my advice to them is that they should ask any really competent French polisher whom they may meet with what he uses in his polish. If he thinks fit to be candid, he will admit that shellac and spirit form the best; but it is within the bounds of possibility that he will not care to say too much about his methods.

To make a good average polish, neither too thick nor too thin, about 6 oz. of shellac to each pint of methylated spirit will be required. The proportions vary according to the fancy of the polisher, and, perhaps, to some extent according to the nature of the work he is engaged on chiefly. Be that as it may, great exactitude in the proportions is not necessary, and I know more than one good polisher who makes his polish almost by guess-work. Of course, if it turns out too thick, the polish can be thinned by merely pouring in some more spirit, while if it is too thin, the deficiency can be made up by dissolving some more shellac in it. A rough-and-ready way of measuring the proportions is to put some shellac in a bottle, or say, for explanatory purposes, half fill it with the lac, and then fill up with ordinary methylated spirit. This is, perhaps, as good a method as any, so it will be seen there is not much trouble involved.

The shellac gradually dissolves, and the solution is hastened by an occasional shaking or stirring with a stick. As many directions, ostensibly published for the benefit of the amateur, recommend the application of heat—one of them which I read lately actually saying that the mixture should *be boiled!*—let me emphatically say that heat is not necessary, and that an attempt to boil the spirit would probably end in disaster. I prefer, as a rule, not to find fault with wha

has been written by others, and I only do so now in order to warn readers that the preparation of polish by heat is dangerous, and should not be practised except with the utmost caution, if at all. In confirmation of this, I may say that I have seen many policies of insurance covering furniture manufactories and shops, where, of course, polish is constantly used, and I think most of them —indeed, I cannot remember an exception —have had a clause to the effect that polish, if made on the premises, must be prepared cold. With this I must leave this part of the subject for the readers' personal consideration. If they are bent on using heat, they do so at their own risk, and must not blame Work for any disaster which may happen.

Two kinds of polish are used, one of them nearly colourless, and known as "white polish," the other darker, and known as "brown polish," or simply "polish." If unqualified by the word "white," this latter kind is always understood.

The white polish is made by using white or bleached shellac, while the other is made with ordinary shellac, either orange or reddish-brown.

Either polish may be used on any kind of wood, except where great purity of tint is required, and, roughly speaking, the white is to be preferred for all light woods, such as light oak, ash, sycamore, satin, etc., while the brown may be used on darker kinds. Even on these I am inclined to think that white polish is, if not better, at least equally good, the only ordinary furniture wood in connection with which a decided preference might be given to brown being mahogany. It will be understood that, when distinguishing between brown and white polish for dark woods, the higher branches of the polisher's art are being touched on, and under ordinary circumstances either may be used indiscriminately. We all know the old saying about doctors differing, and if the word doctor is taken in its literal meaning of "learned man," it may be conceded that men learned in all that pertains to polishing do differ to such an extent that the present writer, at all events, cannot in his person answer the question, "Who shall decide?" He, nevertheless, states his opinion, for which he has equally good reasons (to himself) as those who differ from him have for theirs. Is there not a couplet which wants to know—

> "Where can all this difference be
> 'Twixt Tweedledum and Tweedledee?"

and many a good polisher may, and does, think that any distinction between white and brown polish on dark wood is equally as unimportant.

However, as white polish may be used on dark, and must be used on light woods, if they are to be kept light when finished, and brown can only be used on dark woods, it will be seen that the white polish is the more useful of the two, so that those who do not care to keep both kinds may confine themselves to it. It costs a little more, from the slightly higher price of the bleached shellac; but the extra cost is a mere trifle—so small that it is hardly worth considering by those who only use small quantities, while those who have occasion to use polish in larger quantities can easily have both kinds.

But it may be asked whether the polish cannot be bought ready made, and if so, whether it is not equally good? The first question must be answered in the affirmative, but the second requires more consideration.

Undoubtedly, it would be too much to say that polish bought ready made may not be equal to that made from the recipe given, for there is nothing to prevent manufacturers using the same ingredients, and I cannot say whether many of them do not. At the same time, from the impossibility of knowing the ingredients in polish which is got ready made, there is always some risk attendant on its use, or perhaps it will be better to say, a degree of unreliability which is not experienced when one prepares his own. From the price at which some polish is sold, it is only a fair inference to suppose that something cheaper than spirit and shellac alone have been used; and without saying that good polish may not be bought, it is better for the user, when he wants something that can be depended on, to prepare his own. He knows then what he is using, and in the other case he does not. The bought polish may have nothing in it to prevent it being thoroughly good in every way—brilliance, clearness, and durability—but the fact remains that those who are best able to judge do, as a rule, prefer to make their own polish when they want to do the best class of work. Possibly there may be a certain amount of prejudice in this preference—and from a manufacturer's point of view this might be attributed as the sole reason—but then we are considering the question rather as consumers than as manufacturers.

Possibly many manufacturers, and some polishers, may even assert that the gums or resins they use in addition to shellac even improve the quality of the polish, when used with knowledge and discretion. I am not prepared to say that such additions—please note I have not called them adulterations—may not do so to a certain extent in certain directions—for instance, one gum may give increased elasticity, while another may harden the film—but for a good all-round polish, which can be relied on, there is nothing to surpass the one named. However, as all may not share this opinion, I hope on some future occasion to give several well-approved and frequently-recommended formulæ for forming other polishes, in order that those who feel inclined to do so may experiment for themselves. It will be found that shellac is the principal ingredient in them all, and that those who cannot polish with shellac and spirit alone will not be able to do any better with them; therefore, I hope no novice will remain under the impression that he will do better by-and-by, when he gets another kind of polish to work with.

## WIRE-WORK IN ALL ITS BRANCHES.

BY JAMES SCOTT.

Crimping—Properties of Extending and Decreasing—Putting Together—The "Start" for the Latter—Turning Over—Squeezing Down—Various Meshes—Guiding Boards—The Slides.

The salient points connected with Mr. Bellamy's crimping machine consisted of the use of pairs of cog wheels, fixed after the manner shown in Figs. 19 and 20. A coil of wire was supported by the "swift" (described previously) facing the edge of the machine, the worker traversing the length of the shop, pulling the remainder of the wire behind him, which was finally cut up into the required lengths. The "crimps" were regulated according to the size of the wheels and the cogs thereof, and the distance apart from each other that they were fixed. In Fig. 19 the wheels are shown at a certain proximity to each other, and therein is also noted the crimps of the wire as a result of its being drawn through the wheels; while in Fig. 20 are shown the same sized wheels, but with larger cogs, and the same sized wire represented as passing between them, the result, in the latter case, being a longer crimp. If the crimps, however, are deeper or shallower than a certain limit, it will be impossible to place the wires together so that they may hold themselves properly. The wheels are so regulated as to be adjustable to various degrees of distance from each other, for the reason that allowance must be made for the various gauges of wire to be crimped between them as previously explained.

The Mr. Bellamy who carries on the wire trade in London, concerning whom I may be permitted to say a few words later on, has improved upon his father's ideas; but as the patent has been long expired, I cannot consider myself justified in giving either explanatory details or drawings of his improvements; nor, indeed, of seeking his permission to do so, for, were I to adopt the latter course, I feel sure he would, as a friend, hardly refuse, and my conscience then would accuse me of having taken a mean advantage of our mutual acquaintance.

"Putting together" is the technical term for crossing the wires over and under one another. The wires have to be cut into the required lengths by means of the shears, preparatory to being "put together." In commencing, one wire is placed across the bench as in Fig. 21, A. Another is then placed across it *at one end*, as in Fig. 22, B. Still further, a third, C, is fixed across in the same direction as, and exactly parallel to, the first, A. Here care must be exercised in order that the end of the third wire shall be level with the ends of the first and second wires—that is to say, when the wires are all "put together," the tops and bottoms of them shall in each case follow an imaginary straight line.

The fourth wire, D, is next put across in an exactly parallel line to B (Fig. 24). This method is continued until sufficient wires are placed over and under each other to assume an appearance similar to that presented by Fig. 25. This completes what is called the "start."

The usual practice is to place a weight of some sort upon the "start." The "putting together" can then be continued from either end—there is no necessity whatever to work at both sides alternately when the "start" has been completed—until sufficient length has been obtained. The workman can, if he has sufficient wire, make, by these means, dozens of yards of fencing in a comparatively short space of time.

My earnest advice to anyone who thinks he may wish to use this kind of work for some purpose or another is, unless he makes sufficient at the beginning, to always keep the "start" by him. When he has completed a length to suit himself, he should undo from the remainder the wires which constitute the "start," and lay them by for another time. It apparently appears a comparatively easy and simple matter to make the "start," but, in truth, this is a very difficult affair indeed—the continuance of "putting together" is decidedly very easy labour when considered in connection with "putting together" the "start."

Fig. 26 shows a section of crimped wires when "put together," and from this diagram it should be plainly comprehended how each wire crosses over and under its companions. It is essential, when making the "start," to

Fig. 25.—The "Start," a Result of the Continuation of "Putting together," as in Figs. 21, 22, 23, 24. Fig. 26.—Section of Crimped Wire Mesh. Fig. 27.—A Frame. Fig. 28.—"Turning Over." Fig. 29.—"Squeezing Down." Figs. 30, 31, 32.—Diagrams showing how a Number of Wires when put together can be lengthened or shortened in Distance bodily. Figs. 33, 34.—Two more Forms of Crimped Wire Meshes. Figs. 35, 36, 37, 38.—Method of putting together Square Meshes; it is preferable to work from the Reverse Position to that in which the Wires are here placed. Figs. 39, 40.—Guiding Boards: Wires supposed to be crimped, but shown straight to avoid confusion.

allow the wires to project a distance beyond the points at which they cross each other (E, Fig. 22). The reason for doing this is that there shall be sufficient length to enable the worker to "turn over" the wires—*i.e.*, when the put-together piece is attached to a frame, the parts of the wires which come in contact with the frame (Fig. 27) should be bent over it by means of the pliers (Fig. 28).

When attaching the wires to a frame, temporarily secure them by "turning over" a wire here and there on each side. Then turn each wire up and partly over in consecutive order, and clip off, by means of the nippers, what may be considered superfluous. Finally, "squeeze down" each wire with the aid of the nippers or pliers, whichever may be considered the most convenient method. The use of the nippers for this latter part of the work will be found to be the best for the larger sort, but the pliers are to be preferred for the smaller descriptions. Fig. 29 represents "squeezing down."

It will be noticed that when crimped wires are put together they are capable of being stretched bodily to a great length and also closed together. The best illustration to name to most appropriately explain this stretching and diminishing is to allude to the groundwork upon which we remember to have been pleased, in our younger days, to have fixed imposing wooden soldiers, and of which the same idea is made use of extensively in connection with window blinds, etc. Fig. 30 shows a number of wires as when first "put together," and Fig. 32 the same wires when stretched, or, more properly speaking, extended; while Fig. 31 gives an idea of the same when closed together.

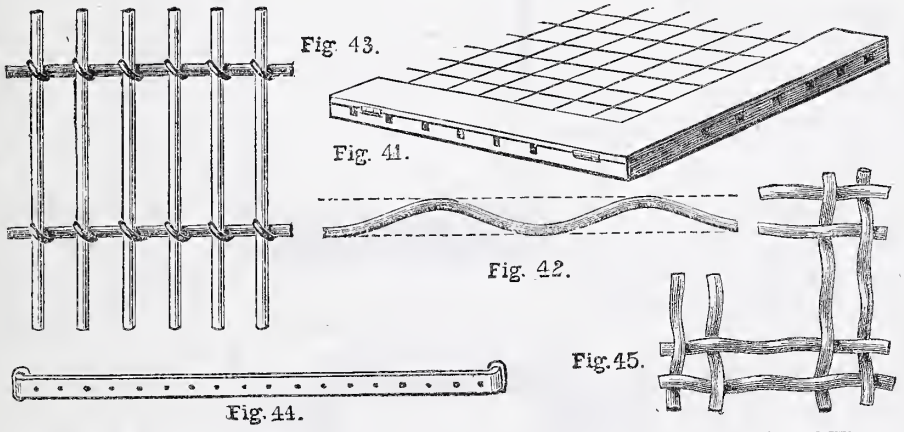

Fig. 41.—Guiding Board, Wire Straight instead of Curved. Fig. 42.—Section of Crimped Wire to explain use of Guiding Boards in Figs. 39 and 41; Fig. 40 is a Plan (open) of Fig. 39. Fig. 43.—Section of Laced Work. Fig. 44.—"Slide" used in making Mesh, shown in Fig. 43. Fig. 45.—Another Pattern for Interlacing Crimped Wires.

Sometimes the wires are fixed "two-and-two," as in Fig. 33. To do this, when the first and second wires are laid across each other, another wire has to be placed, in each case, on the outside of them, parallel, as in Fig. 24; the work is then continued in a similar manner as in the single wire mesh, allowing two or more crimps to intervene alternately.

Another mesh is the square one shown in Fig. 34. The only difference between the construction of this and the diamond mesh consists in the laying of the wires at right angles across one another, as shown in the progressive diagrams, Figs. 35 to 38, they being placed over and under each other in the same way as those composing the diamond mesh.

Sometimes "guiding boards" are used to assist in "putting together," but my practical friend does not advise their adoption, as they are sometimes rather awkward to handle, and when the worker has learnt to "put together" wires by their aid, he will wish he had striven to perform the work without any such assistance on the part of accessories, as the time occupied by a man in constructing a piece of work by these means will be far in excess of the time occupied by a workman in making the same sized portion by merely trusting to his dexterity of hand, without any "guiding boards." But these things may be considered by some to contain a mite of usefulness, so I must take this reason as my excuse for proceeding with a brief description of them.

In Fig. 39 is shown a section of one for use in connection with the diamond mesh. It is merely two boards, an inch or so in width, of a length considered desirable, and about ½ in. thick, together, with holes bored through it in the manner shown in Fig. 40. They would be hinged together, and secured with a hook and eye at each end. The wires are placed through this from the side marked A, either in the order already described—*i.e.*, across each other progressively—or else one set of parallel wires fixed first, and then the cross wires connected with them in the opposite direction. For the square meshes, a rectangular board, as shown in Fig. 41, could be used, also hinged, and with hooks attached to the ends.

The holes in these guiding boards should be, in width, the same as the gauge of the wire; but they should be in depth just sufficient to receive the crimps of the wires; by this I mean that the space occupied by the crimping, as indicated in Fig. 42 by the dotted lines, should be the same as the depth of the holes (Fig. 41), in order that the wires may be held in their proper position, instead of the crimps laying upon their sides, as they are apt to when being "put together" in the usual manner.

An extensively-used mesh is that shown in Fig. 43. The wires forming it are "put together" by the humble aid of an accessory which rejoices in the appellation of "slide." This appliance, I must say, is a very handy one, and its use is, contrary to that of the guiding boards, recommended. It is a very simple affair, and a sketch of it is given in Fig. 44. It is but a strip of metal or wood, with holes through it, and is secured to the bench. In "putting together" a piece of work of the pattern shown in Fig. 45, the long wires are placed through the slide, allowing the front ends of them to project for a short distance, and to them, at this part, is temporarily fastened a cross wire, which latter is finally laced to the long wires. The latter are then drawn partly through the slide, and cross wires laced at equidistant and, of course, parallel points to the first. When the first cross wire has been fastened, proceeding with the work is almost the same as if the wires were in a frame, for the opposite ends to those to which the first cross wire is laced being in the "slide," they are there restrained from closing together, or otherwise becoming inconvenient to handle.

It is a usual practice, with this description of work, to lace the alternate wires in an opposite way to the others, *i.e.*, the first, third, fifth, and so on, would be laced from left to right, whilst the second, fourth, sixth, etc., would be secured by the lacing wire travelling from right to left. Sometimes the middle one or two only, according to whether an odd or even number of cross wires are used, are laced in a reverse direction.

I said, a short while ago, that perhaps I should be permitted to say a few words concerning Mr. Bellamy, one of the sons of the inventor of crimped wire.

My many readers must certainly recall the fact, now I come to mention it, that in my numerous contributions to WORK during the past, I have never recommended or made allusions to anyone by name. This was not on account of my not wishing to do so, but for the sole reason that I was entirely ignorant of, and unacquainted with, anybody connected with wood-work who was worthy of more consideration than his fellows in that craft or trade. I do not mean to say that I do not know any good workmen, for I should be telling an untruth were I to declare so; for my trade acquaintances consist of both good and bad workmen—although I believe honestly that the majority of them belong to the former class. They are good "workmen," and good "men" without the "work"; and I must add, that although I think they are good men *without* the "work," I also think, paradoxically, perhaps, that they are *better* men *with* the WORK. Therefore, if recommendations were due to one, they were likewise due to the remainder; and to name the whole was entirely out of the question.

But, with regard to wire-work, I am placed in a different position, for I am only acquainted with the family of Bellamy and the workpeople whom they employ; therefore, I deem it not out of place to mention his address. I do not promise that he *will* satisfy everyone, nor do I say that he will satisfy *anyone*; but I *do* say that my belief is, that anyone and everyone who may apply to him will not meet with disappointment.

This is meant for those who may wish for any articles made in wire, and who do not care to construct them personally. His address is 40, Penton Place, Pentonville, London, N. I do not know that he would supply crimped wire in small quantities, but I have no hesitation in saying that reasonably large quantities would be attended to. It does not require an abundance of intelligence to understand this. In a shop where several people are at work, there is a chance of their time being lost, to a certain degree, if they are called from a large job to perform comparatively small ones.

The same with finished articles; if but one or two are required, I may advise the reader to communicate with me through

the Editor (with his permission), and I will see what I can do through the influence of a relative of Mr. Bellamy, who is in his employ, and who is always willing and ready to do a little "overtime."

Of course, straight wire can be obtained from several places; and, indeed, I do not think that any wire-worker, who may be in the same locality as where the reader may chance to reside, would refuse to supply him with crimped wire, for every wire-worker must have a crimping machine; the only difference being that that belonging to Mr. Bellamy contains a few improvements upon the others capable of saving his and his workpeople's time to a certain extent. But I see no reason why any reader should not "knock up" a pair of wheels to answer the purpose. In a former paper, I have given what I consider to be a sufficient description of the crimping machine.

## A SIMPLE BRACKET FROM SOUTH KENSINGTON MUSEUM.

BY URQUHART ARNOLD.

Small Things at South Kensington Museum—Art Work—Plain Bracket—Decoration of Bracket.

The remark that there are many wonderful things in the Museum at South Kensington may seem on an equality for triteness with that of the philosopher who assured his audience that he "admired Shakespeare's works because there was a good deal in them." Of course, we all know that nowhere in this country, at any rate, if in any other, are there so many art treasures collected together as at South Kensington. Naturally I take, perhaps, more interest in the wood-work there than in anything else, and, no doubt, so do many of the readers of Work; but I could not help thinking, as I was mooning away a few hours—as I am very fond of doing when I have an idle evening in London—that one sometimes misses many a lesson by neglecting the comparatively unimportant objects. I was started on this train of thought by noticing a small bracket something like that shown by Fig. 1. I only jotted it down roughly on a scrap of paper, and the drawing is principally from memory. It is such a very simple thing that it might appear to be too insignificant to say anything about it, and being from memory, as said, it may not adequately represent the original. It is, however, just on account of its simplicity that it is worthy of some notice; for we are rather too apt to exclusively devote our attention to the great masterpieces of work—such, for instance, as the Boule wardrobe in the Jones collection—instead of keeping our eyes open all round.

The bracket which occasions these remarks has not even the merit of being "very old"—a qualification which to many seems a necessity if a piece of art work is to be admired; neither is it costly, so that there is nothing, apparently, about it which distinguishes it in any way, or places it above the lowest level of mediocrity. That it is unique I do not say. It is even commonplace, if you like to call it so—nothing more than the application of artistic principles in the production of an ordinary little bracket, which can be made by any joiner with the commonest tools from a few bits of pine boarding.

When we talk of art work, or the production of anything artistic, are we not rather inclined to conjure up visions of æsthetic (I use the word in its popular or derisive sense) looking individuals, with sad-coloured garments, and a general air of unconth angularity, mentally struggling to bring forth something fearfully and wonderfully devised? I do not say anything new when I say that the simplest thing may, and ought to be, a piece of art work in the widest acceptation of the term. Decoration is not, in itself, a necessary feature of art workmanship. Lavish ornamentation is apt to be anything but artistic, unless applied with skill, which all of us do not possess. On the other hand, by due attention, most of us can produce things which, if not in the highest form of art, as applied to our several crafts, shall yet be artistic and true. My conception of art may be different from yours, but I hold that any article, if it be designed with due regard to its intended purpose, and be carefully made, is in the truest sense a work of art—I do not say a great work of art—and worthy of regard. The little bracket, I venture to think, fulfils these conditions. A bracket is to support something. Is not this one evidently designed to do so? Is it well made? The answer depends on the worker. If he is careless with the work it will not be.

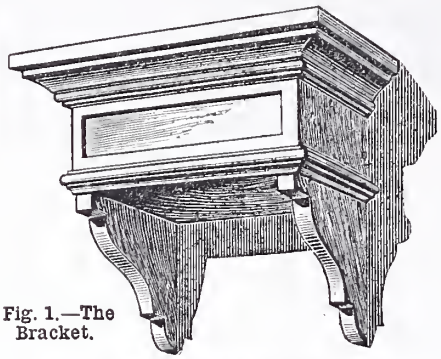

Fig. 1.—The Bracket.

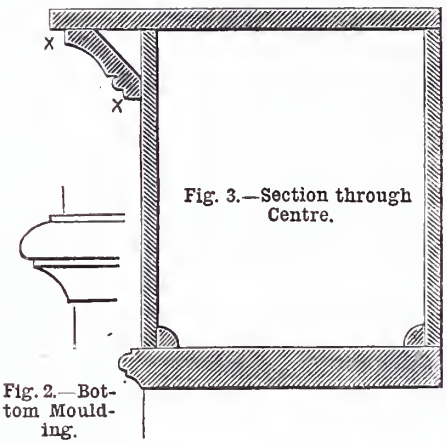

Fig. 3.—Section through Centre.

Fig. 2.—Bottom Moulding.

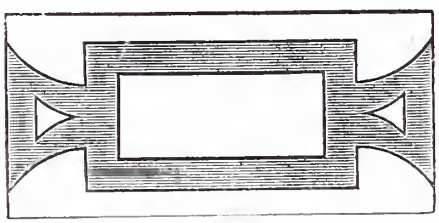

Fig. 4.—Gilding on Front.

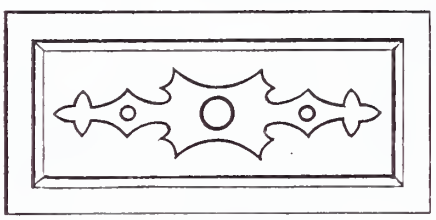

Fig. 5.—Suggestion for Inlay.

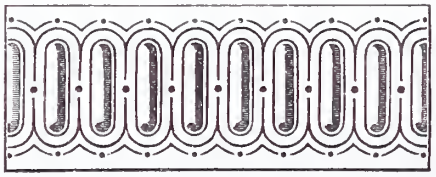

Fig. 6.—Suggestion for Carving.

Now I have done with my little homily on art, and we may turn to the actual making of the bracket, or rather, give a few hints about it. The construction is so simple that any boy almost could manage it; so that those who aspire to work in wood but do not know how, or have not the skill nor the tools to do anything big, may succeed with it. If they like to decorate the bracket afterwards, there is no reason why they should not do so.

Now, I do not pretend to say that the bracket in the Museum is made in the way I am about to suggest—I have had no opportunity of examining its construction, so that I cannot tell what it is—but there is no reason to suppose that it differs widely from that suggested here. The size, also, is a matter of secondary importance, for that can be altered or arranged to suit the requirements of the user. As shown in Fig. 1, the bracket is oblong on top, but there is no reason why it should not be square if that shape suits better.

The first thing will be to make a box, minus top and bottom, of, let us say, ½ in. stuff. On front and two ends of the upper part of this, plant a simple moulding, mitred at the corners. The bottom of the box extends beyond the front and ends, and is moulded at these edges, as shown in Fig. 2. On a line with the ends of the box, brackets are to be screwed, or otherwise fastened, to the lower side of the bottom, to which the box may be fastened from above with blocks of wood glued into the angles. The top may then be nailed on. If the appearance of the nail-heads be objected to, dowels may be used instead, and, by being inserted in the ends first, need not come through. An alternative plan is to make the part I have called the box without back, and then to fasten the top on with blocks, as suggested for the bottom.

Fig. 3 represents the construction in section from back to front, and is so clear that comment is superfluous.

The bracket will look well finished in almost any way; but it may be interesting to state that the original is black, relieved with gilt lines on the parts marked × in Fig. 3. The front of the box also has gilt lines instead of a panel, as indicated in Fig. 1.

Another bracket (there are several of them of the same design, but varying in size) has the front of the box part decorated with gilded lines, as shown in Fig. 4, which at once suggests that a piece of overlaid fret of the same pattern may be used, the corners being mitred for the sake of neatness. A small inlay of bold design, and surrounded by a neat moulding, would also look well, and it is needless to say that if the front is carved, as it easily may be, in a suitable style, the value of the bracket will be increased.

As suggestions for what may be considered appropriate, without entailing much or difficult work, Figs. 5 and 6 are given for inlay and carving respectively.

Alterations and variations from the

original might be suggested at almost indefinite length, till by the process of evolution something totally different in style and design results. It would be interesting to illustrate this; but as there are other subjects besides wood-working which require the space which would be occupied in doing so, and enough has probably been said to enable those who wish to contrive for themselves, I must—at any rate, for the present—take leave of the unpretending little South Kensington bracket.

## TO PREPARE FRESH-BURNED CHARCOAL IN SMALL QUANTITIES.

BY E. W.

General Observations—How to Make—The Wood to Use—Culinary Uses.

*General Observations.*—Although charcoal is cheap, and everybody that has frequent need to use it may avoid a complete exhaustion of their stock by a timely renewal, yet it will not unfrequently happen that many, especially amateurs, who only occasionally have any use for such, cannot so conveniently get it in the time of need as could be desired. Perhaps only a small quantity is wanted for some special purpose; it may be for a small job at brazing, or perhaps a supply of fresh-prepared carbon for chemical purposes. In cases like these it will often be far better to make than to buy.

*How to Make.*—If there is clay at hand, and a thin coating placed around a piece of wood, a small puncture hole being left for the escape of steam and gases, and the whole placed in a good fire, the wood will quickly become charred, but not consumed, and when taken from the fire separates readily from the burnt clay. It is desirable, however, when time permits, to let the clay dry slowly before burning.
